CASE 6.—Male, complained of retention of urine for four days. Two years earlier he had two attacks of retention of urine, at 15 days' interval, lasting 24 hours, accompanied by pain and swelling in the right loin, relieved by the passage of a stone and large quantities of urine. Examination: Indefinite swelling in right loin with dullness in front. On catheterisation no urine was drawn from the bladder. Right kidney was drained, and 200 c.cm. of urine drawn. Patient's condition steadily got worse, and he died on the twenty-fifth day after the operation. Post-mortem: Perinephric suppuration round the right kidney, which was in a condition of pyonephrosis. Two stones in right ureter, one about middle, the other at ureteric opening; left kidney in a condition of hydronephrosis. Lumen of left ureter almost obliterated at ureteric opening.

CASE 7.—Male, complained of retention of urine for four days. Examination: Both kidneys in a condition of hydronephrosis. Bladder empty. Both kidneys drained from loin. Patient died ten days later. Post-mortem: Both kidneys in a condition of marked hydronephrosis, with very little kidney substance left. Both ureters were dilated, except at a point just above ureteric opening, where lumen was almost completely obliterated.

CASE 8.—Male, complained of retention of urine and pain in right side for four days. Bladder empty. Diagnosis of calculus in right ureter made. Right kidney exposed from loin and found swollen. It was incised, and its pelvis was found slightly dilated, but did not contain any stone. A catheter could be passed down the ureter, but only as far as a point near the bladder. A drainage-tube was inserted in the pelvis of the kidney. Patient died three days later with signs of uræmia. Post-mortem: Right kidney in a state of slight hydronephrosis. Right ureter dilated, except for lower 3 cm., where it was represented by an impervious fibrous cord. Left kidney in a condition of advanced hydronephrosis, small in size, but with no kidney substance left. Left ureter in a similar condition as the right. Bladder showed signs of old-standing bilharziasis.

CASE 9.—Male, complained of retention of urine for seven days. Examination: Tender swelling in the abdomen with rigidity of the abdominal wall. Pulse was rapid and respiration thoracic. A diagnosis of acute peritonitis was made. Laparotomy was performed and the abdominal cavity was found to contain urine. Both kidneys were large and in a state of advanced hydronephrosis. A small rupture was discovered in the left kidney, from which urine flowed into the general peritoneal cavity. Left kidney was removed and right drained from the loin. Patient died on the second day of the operation. Post-mortem: Lumen of right ureter obliterated in its lower 3 cm. and dilated above this. Left kidney in a state of hydronephrosis. Left ureter in a similar condition as the right. Bladder showed signs of old-standing bilharziasis.

CASE 10.—Female, aged 21, complained of severe pain in the right loin and incontinence of urine. Gave a history of several attacks of renal colic in the right side. Attacks were followed by the passage of blood-stained urine mixed with pus. On examination right kidney was found tender, enlarged, and cystic. Left kidney could not be felt. Urine: Alkaline, sp. gr. 1015, contained blood, pus, albumin, and bilharzia ova. X ray examination negative. Cystoscopy was not practicable. Operation: Nephrectomy; kidney showed extreme hydronephrosis with a mild infection. Patient passed 400–800 c.cm. urine mixed with blood daily after the operation. She gradually got worse, and died on tenth day after operation with symptoms of uræmia. Post-mortem: Left kidney showed moderate degree of pyonephrosis; lumen of right ureter in lowest 2 cm. almost completely obliterated, upper part much dilated; left ureter in a similar condition; bladder showed no signs of bilharziasis. An empyema on left side of chest.

CASE 11.—Male, aged 40, transferred from the medical section with a diagnosis of calculus anuria. History of anuria for four days with severe pain in the right lumbar region. Operation: Right lumbar nephrostomy. Kidney was found hydronephrotic. No calculi found. Catheter passed down the ureter stopped near the bladder. Patient died of uræmia three days later. Post-mortem: Right kidney hydronephrotic, left small, being represented by a fibrous sac containing a small quantity of fluid. Right ureter, lowest 3 cm. impervious, rest dilated. Left ureter in a similar condition. Bladder showed signs of old bilharziasis.

Diagnosis.—The diagnosis of these cases in any stage depends upon: (1) Recognition of bilharzia ova in the urine; (2) absence in radiographs of the shadow of a stone in the kidney, ureter, and bladder; (3) cystoscopy. Of these, cystoscopy is by far the most important. For although the actual lesion is inside the ureter, one would be quite justified in concluding that the lesions seen at the ureteric opening are but a continuation of the same process higher up.

Differential Diagnosis.—This, in all stages, is mainly from calculus. It must, however, here be emphasised that the two conditions may coexist, and that an attack of renal colic in a patient with ureteral bilharziasis may be due to the passage of a renal calculus. Hence the importance of careful radiography.

Treatment.

Only in the first stage of the disease may tartar emetic be expected to effect a cure. Early diagnosis is therefore the only way of saving the patient's life, as the later stages are always fatal. The surgeon must, however, always keep in mind that while one kidney may be disorganised, the other may be still in a condition amenable to treatment by tartar emetic. During the attacks of renal colic treatment along the usual lines is all that is needed.

In the second stage nephrectomy for hydronephrosis and pyonephrosis is justified if the disease is unilateral, which is, however, very uncommon. Abdominal nephrectomy will be found much easier than the lumbar operation, which is sometimes rendered impracticable owing to the shape and size of the diseased kidney. It is of vital importance that the function of each kidney should be estimated separately before any such operation is undertaken since the hydronephrotic kidney may be the only one that is functioning, the other kidney having been destroyed at an earlier date. If the disease is bilateral tapping the kidney through the loin by a Potain's aspirator will often relieve the patient for two or three months, when the same process may be repeated if necessary.

In the third stage no treatment is of any avail. Nephrostomy does not seem to modify the progress of the condition in any way.

Summary.

1. Bilharziasis of the ureter exists, and may be the only, or the most prominent, manifestation of the disease. The disease is usually bilateral, though more advanced on one side than on the other. The disease is very chronic, and the stages merge one into the other.

2. The disease ends in the formation of fibrous tissue, which replaces the normal coats of the ureter. This leads to contraction and narrowing or even complete obliteration of the lumen of the lower part of the ureter. Secondary to this the upper part of the ureter and pelvis of the kidney become dilated.

3. Ascending infection is rare, and is mostly a complication of bilharziasis of the bladder.

4. The disease, if neglected, is very fatal, ending in death, usually from uræmia and rarely from septicæmia.

My thanks are due to Dr. Anis Onsy Bey, clinical pathologist to the hospital, who prepared all the specimens for me, and to Dr. M. Erfan and Mr. A. W. Mooro, registrars at the hospital, for their help in the preparation of this article.

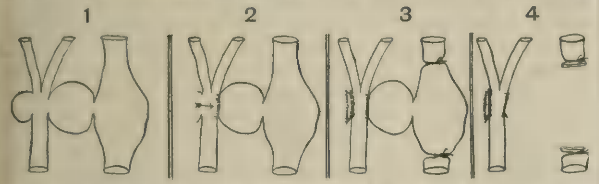
A CASE OF
ARTERIO-VENOUS ANEURYSM OF THE NECK.

BY A. W. MOORO, F.R.C.S. ENG.,
SURGICAL TUTOR AND REGISTRAR, KASR-EL-AINY HOSPITAL, CAIRO.

THE case here described illustrates several points of surgical and medical interest.

The patient, a labourer aged 39, was admitted under my care, nine months after a gunshot wound of the neck, with all the signs and symptoms of an arterio-venous aneurysm of the left common carotid artery near its bifurcation, as well as the type of sensory aphasia known as word-forgetfulness. Operation was advised on account of the patient's distressing insomnia and the fact that the aneurysm was gradually getting bigger.

Operation.—Anæsthetic, chloroform and ether; duration, two and a half hours. The left side of the neck was opened up by a Z-shaped incision over the sterno-mastoid muscle. The latter was cut near its origin and turned upwards. Crile clamps were applied to the common carotid and the internal jugular at the root of the neck, and to the internal and external carotids and the upper part of the internal jugular. One clamp sufficed for both the internal and external carotid arteries. Dissection then showed the condition to be a varicose aneurysm, the size of a walnut, of the common carotid artery and the internal jugular vein, together with a small saccular aneurysm, the size of a hazel-nut, on the opposite side of the artery, and extreme dilatation of the corresponding part of the vein (Fig. 1). The vagus nerve was adherent to the arterial aneurysm and on it was a traumatic neuroma about 8 × 4 mm. The cervical sympathetic was not implicated. The arterial aneurysm was first excised. Through the opening thus produced, the communication between the artery and the other sac could be clearly seen and was closed by a continuous "Matas" suture of No. 000 silk sterilised in liquid paraffin, penetrating the intima and muscularis only (Fig. 2). Then the wound resulting from excision of the arterial aneurysm was closed by Dorrance's method (Fig. 3). Lastly, the dilated portion of the jugular vein, together with the varicose aneurysm were totally excised between two ligatures (Fig. 4). The wound was kept wet with liquid paraffin all through the operation. On removing the Crile clamps, pulsation returned in the now slightly constricted artery, and there was slight oozing through the Dorrance suture, but none through the Matas suture. The oozing, however, stopped almost immediately on the application of a piece of muscular tissue. The sterno-mastoid was then sutured in position and the area of operation drained by a small tube inserted through a separate skin incision.



Diagrams showing the steps of the operation.

FIG. 5.

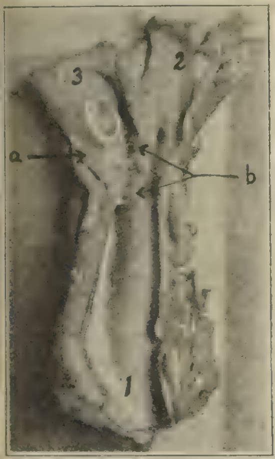


FIG. 6.

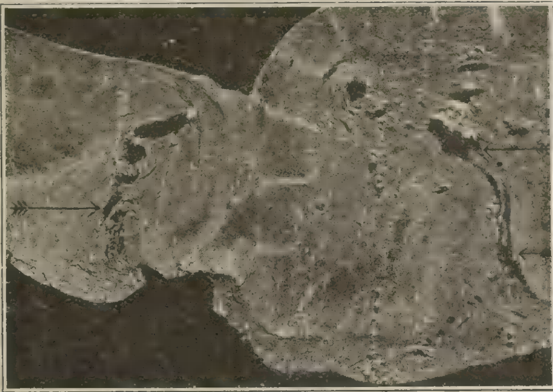

FIG. 7.

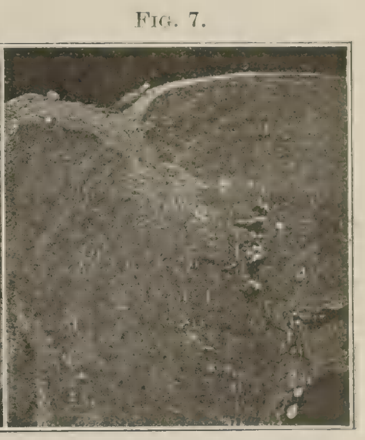

FIG. 5.—Common, external, and internal carotid arteries, slit open (two-thirds natural size). 1, Common carotid; 2, external carotid; 3, internal carotid; (*a*) scar after intra-arterial non-penetrating suture; (*b*) scar after Dorrance's penetrating mattress suture.

FIG. 6 is a microphotograph of a transverse section at the site of the Dorrance suture, showing eversion of all the layers of the arterial wall as well as the tract of the silk suture. The endothelium appears as a faint light border to the darker muscularis. The arrows indicate the tract of the silk thread. FIG. 7 is a microphotograph of a section at the site of the intra-arterial suture.

Progress of Case.—There was some superficial sepsis in the lower part of the wound which soon cleared up, the wound having completely healed on the eleventh day. The patient, however, developed double broncho-pneumonia on the day following the operation and died of it on the thirteenth day.

Autopsy.—The lungs were both the seat of advanced broncho-pneumonia going on to abscess formation and commencing gangrene. The brain showed an area of old softening the size of a half-crown in the posterior part of the left temporal lobe—evidently the result of an embolus produced by the gunshot wound of the artery. The lumen of the artery was patent and smooth. There was no trace of ante-mortem clot. The aneurysmal opening, which was closed by a continuous suture from the inside, was hardly apparent to the naked eye. The wound, which was closed by mattress suture from the outside, showed the line of suture apparently covered by endothelium (Fig. 5).

Paraffin sections of the artery at the site of the operation (Figs. 6 and 7) showed that: 1. Both openings had healed completely, and the lines of suture were completely covered over with endothelium several layers thick. 2. Although cosmetically the intra-arterial suture was superior to the Dorrance suture, healing had taken place by means of much more fibrous tissue in the former than in the latter.

This case, therefore, supplied the following interesting information: 1. Gunshot wound of the common carotid artery as a cause of cerebral embolism, resulting in word-forgetfulness. 2. The microscopic appearance of a healed arterial wound 13 days after its infliction and suture. The case further illustrates the relation between "word-forgetfulness" and a lesion of the posterior part of the left temporal lobe of the brain; and the fact that a lesion of one vagus nerve is compatible with a normally functioning heart.

I am indebted to Drs. A. Girgis and M. Ragheb for the paraffin sections and the photographs.

CHRONIC PROSTATITIS AND LUPUS ERYTHEMATOSUS.

BY E. T. BURKE, D.S.O., M.B., CH.B. GLASG.,
V.D. OFFICER, COUNTY BOROUGH OF WARRINGTON; ASSISTANT SURGEON, GENITO-URINARY DEPT., WIGAN ROYAL INFIRMARY; ASSISTANT M.O., DERMATOLOGICAL DEPT., ROYAL INFIRMARY, MANCHESTER.

LUPUS erythematosus is a chronic inflammatory disease of the cutis, possessing special characteristics, and due to a toxin circulating in the blood. It is, in its essence, a toxic erythema of a non-specific character. The French view, that it is caused by the toxic products of the bacillus of tuberculosis, is true only in a certain small proportion of cases. In most instances it is not possible, by any clinical or other means, to demonstrate the presence of a tuberculous focus in any part of the body. Indeed, considering the high incidence of tuberculosis in the community, one would expect—were the French view correct—to find lupus erythematosus much more frequently than one does. The source of the toxin is undoubtedly in some cases a tuberculous deposit in the lungs;

but it is much more often to be found in a non-tuberculous condition elsewhere.

A pyorrhœa alveolaris, a chronic tonsillitis or rhinitis, a chronic intestinal infection, may each be the underlying cause of the disease. Such conditions are comparatively common, and, if one includes tuberculosis, it is not unwarrantable to assume that the greater proportion of the population can be labelled with one of them. It would therefore appear—when one considers the comparative rarity of lupus erythematosus—that there must be some other causes which determine the outbreak of the disease in certain people.

In many instances it has been shown that a nervous factor is present. Perrin and others record cases in which the disease has appeared after an emotional storm. The typical limitation of the patches of erythema, and the areas generally affected, make an angio-neurotic element appear to be a reasonable supposition. The face—a region in which vasomotor reactions are common under nervous and climatic stimuli—is a favourite site of lupus erythematosus. Its frequent situation in the chilblain areas, and the many close relationships between it and Raynaud's disease, point most decidedly to a vasomotor factor. Trauma can be shown, in certain instances, to have decided the point of outbreak. The position would, then, appear to be that a toxin circulating in the blood may cause no cutaneous symptoms until some other influence comes into play, which, by causing a vasomotor upset in some particular area, gives rise to the condition of lupus erythematosus in that area.

It is clear, then, that the main principle of treatment is to eradicate the toxin and its place of manufacture. Any light that can be thrown upon such foci, and upon the causal organisms, should be of some value. So far as my inquiries go, I have not been able to trace any reference to a relationship existing between lupus erythematosus and chronic gonorrhœa. For that reason the publication of the following case may be of interest :—

An officer in the Mercantile Marine, aged 43, consulted me on Jan. 10th, 1923, complaining of increasing difficulty of micturition and occasional "morning drop." He was infected with gonorrhœa in Bombay in 1910. He treated himself with permanganate injected with a hand syringe, and also took capsules of sandalwood oil. He had "inflammation of the bladder" a few weeks after he commenced this treatment. He consulted a chemist for this, who gave him medicine. He considered himself cured after about two months, although he noticed a glueing together of the lips of the meatus in the mornings. When he came to see me his ship was laid up for refitting, so that he was able to have continuous treatment. He is by no means a total abstainer from alcohol, has had malaria, and was torpedoed in 1916. Several patches of lupus erythematosus were present on the nose, cheeks, and chin, but especially on the nose. This, he stated, had been present for about seven years.

Condition on Examination.—Two urethral strictures, 2 in. and 3½ in. from the meatus. Heavy threads in the last urine. Prostate slightly enlarged, harder than normal, and somewhat nodular. Pus cells and numerous organisms present, but no gonococci found in the prostatic secretion.

Diagnosis.—Stricture. Chronic gonococcal prostatitis.

Treatment.—It was justifiable to assume from the condition and from the history that the prostatitis was gonococcal in origin. Weekly injections of a residual stock vaccine—gonococci plus secondary organisms—prepared by Dr. C. E. Jenkins, pathologist, Salford Royal Hospital, were given for ten weeks. Prostatic massage was performed twice weekly. Weekly dilatation of the strictures was instituted by means of flexible bougies and by the Kollmann's irrigating dilator. Posterior irrigation—Janet method—daily, and atropine suppositories twice weekly. Once daily 2 c.cm. of iodargol were instilled into the bladder and posterior urethra, and a collodion seal applied to the urinary meatus. This seal was kept on for three hours. As it occurred to me that there was a possibility that the lupus erythematosus was a consequence of his prostatic condition, I refrained from treating his facial disease locally.

Course of Case.—During the first four weeks the facial condition became worse, being obviously stimulated into activity by the massage and the instrumentation. From then onwards, the hyperæmia rapidly decreased. By the tenth week it had practically disappeared except one small patch, rather less than a threepenny-piece in size, on the bridge of the nose. This was treated with carbon dioxide snow on the occasion of his last visit. At that time the prostate was normal, the strictures had been dilated to No. 27 French, and urethroscopic examination showed as the only abnormality a slight increase of hyperæmia and prominence of the verumontanum. He was under my treatment till March 23rd, when he returned to sea.

I regard this case as one in which the focus of infection causative of the lupus erythematosus was in the prostate. The patient could not be certain that the skin condition was not present before he was torpedoed, he thought that it was, but he was sure that it became worse afterwards. The nervous excitement of that occurrence, the exposure to sun and wind in a rowing boat for two days under severe mental stress, were, in all probability, the deciding factors for the facial outbreak or its aggravation. He has been engaged principally in the Far East trade, and in consequence has been much exposed to the sun.

I have felt that this case indicates that in every male patient who is suffering from lupus erythematosus, the venereal history should be inquired into; and, whether it be positive or negative, the genito-urinary tract should be thoroughly examined to eliminate the possibility of the focus of infection being situated therein.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Nov. 26th with Dr. HERBERT SPENCER in the chair.

Mr. W. SAMPSON HANDLEY opened a discussion on

THE TREATMENT OF ACUTE SUPPURATIVE GENERAL PERITONITIS.

The subject of debate should, he thought, be restricted to cases of acute unlocalised or unlimited spreading or plastic suppurating peritonitis, threatening to end in death within a few days at most, and due to pyogenic organisms. He proposed to present only the results of his own experience, mainly of peritonitis following appendicitis. The clinical concept of "general peritonitis" was well established, and must not be taken to imply the belief that the peritonitis was universal. This was rarely the case, even post-mortem. The class of case they were dealing with developed, within a short period of onset, the clinical picture of general peritonitis as described in text-books, with a universally distended, rigid, tender abdomen, and repeated vomiting, which became offensive and assumed the type of frequent effortless regurgitation. The passage of flatus and fæces ceased, the pulse became rapid, at first wiry, then running and uncountable. The face became anxious and drawn, and a deadly coldness of hands, feet, and nose finally indicated that death was a matter of hours—a fact of which, under the stimulant influence of the streptococcal poison, the patient was often acutely conscious.

Consideration of Accepted Treatment.

In the accepted treatment of peritonitis developed by Murphy, Fowler, Barnard, and others, immense strides had been made in the last 20 years with regard to prevention, though much remained to be done. It was now universally recognised that in dealing with an acutely inflamed appendix medical treatment was useless, the only rational course being to remove the offending organ within two hours of diagnosis. As even the latest text-books made no distinction between some of the early and late symptoms of appendicitis, avoidable delay in diagnosis still often occurred. The sudden onset, in a patient previously healthy, of acute abdominal pain, soon settling in the right iliac fossa, if accompanied by an initial vomit and by local deep tenderness at the appendix point only, justified the diagnosis of acute appendicitis, in the absence of all other signs and symptoms. It should be emphasised that muscular rigidity and pyrexia were often absent in the early stages. Again, if the case was not a very early one, and especially if there was rigidity in the midline of the abdomen before the appendix was approached, a small median incision should first be made and a gauze swab cautiously introduced to the bottom of the recto-vesical pouch. If pus or dirty fluid was present, a drainage-tube must be left in the pelvis. The appendix was then removed through the same or a separate incision; if no pelvic infection was found, the median incision was closed, and the appendix removed by the usual right iliac incision. The adoption of this rule would often disclose unsuspected early infection of the pelvis, the first stage of a pelvic abscess, or a general peritonitis.

Removal of Septic Focus, Drainage, &c.

An operation for peritonitis was incomplete unless opportunity was taken to remove the septic focus or close the perforation, though in very rare cases the procedure might be impossible or inadvisable. In established peritonitis or intraperitoneal abscess, it was courting unnecessary risk to close the abdomen without providing drainage. Only in massive fouling of the peritoneum by the contents of the stomach or intestine should irrigation be resorted to, and then only with saline at 103° F., mixed to a uniform temperature. Very hot fluid might cause fatal shock. Mr. H. W. Carson in his historical survey of the treatment of peritonitis had rightly emphasised Murphy's method of continuous saline infusion in the milder cases of unlocalised peritoneal infection, a method which had doubtless saved many lives. Lawson Tait's treatment of peritonitis by saline purgatives represented at its time a great advance; it probably succeeded only in milder types of infection, and where exposure, chill, and rough handling of the intestine had inhibited its action for a time. Purgatives, however, were frequently ineffectual either because they were vomited, or because the bowel was too paretic to react to them; they might cause spread of the peritonitis, but were indispensable in the milder forms, although ineffectual in the graver ones. Similarly, eserine or pituitrin might score a triumph in mild cases.

Antitoxins and Vaccines.—"Ileus Duplex."

Experience gave him some belief in the virtue of antistreptococcic serum, if only for its food value where all food was rejected. He thought all vaccines irrational in the treatment of such an acute intense toxæmia as accompanies peritonitis. These standard practices in the treatment of peritonitis, though successful in milder cases, were inadequate in graver peritoneal infections. In these graver cases many surgeons counselled non-interference and despair. He wished to combat this attitude, and to show that many cases of general peritonitis, hastening to a fatal issue in spite of energetic treatment on accepted lines, could be saved by recognition of the fact that the patient was dying of intestinal obstruction. Acute appendicitis passed into general peritonitis by rupture of the appendix from 24 to 48 hours after onset, and by a trickle of pus or foul fluid over the brim of the pelvis to the bottom of the recto-vesical pouch; with a sufficiently virulent infection, the conditions for a general peritonitis were then established. Peritoneal inflammation began at the bottom of the recto-vesical pouch and spread upwards through the abdomen; this fact was the key to successful treatment.

Three stages were recognised: (1) Pelvic peritonitis, (2) hypogastric peritonitis, and (3) terminal or "clinical picture" stage. Even in the last stage the peritonitis was rarely universal. The continued vomiting showed that the stomach and upper intestine retained some contractile power, and were therefore not intensely inflamed. Post-mortem observations confirmed this conclusion. Even in the earliest or pelvic stage of a general peritonitis, intestinal obstruction might supervene, accelerating the upward spread of the disease. With these cases he had dealt in his Hunterian lecture in 1915. There were two points of obstruction in the intestine, the inflamed pelvic ileum and the inflamed pelvic colon; he had named the condition "ileus duplex." It was not sufficient to short-circuit the distended supra-pelvic ileum into the cæcum, for the obstruction in the pelvic colon remained and the patient died. Four such cases out of a total of five ended fatally. If, in addition, a cæcostomy opening was made, recovery was the rule; so far, since adopting this treatment, he had not lost a case. In 1915 he had not recognised, what he now clearly saw, that ileus duplex represented the early stages of a general peritonitis. Prompt treatment demanded early recognition of the clinical signs of ileus duplex. Ignoring local signs in the right iliac fossa due to the previous peritonitis, the usual course of events was as follows: After operation for acute appendicitis, for a day or two all went well, but temperature and pulse failed to return to normal, and on the second or third day vomiting returned, persisted, and might finally become offensive. The passage of flatus and fæces ceased, and there was some distension of the hypogastric region; but there was no muscular rigidity, for at this stage peritonitis was confined to the pelvis. If drainage, saline infusion, purgatives, and enemas failed, prompt operation was necessary. Priority in the recognition and successful treatment of cases of similar character following operations on septic pelvic conditions, such as carcinoma of the cervix, belonged to Mr. Victor Bonney, who advocated treatment by jejunostomy, with subsequent resection of the jejunum a fortnight later when the obstruction had passed off; in his hands this plan had been very successful. His own method of treatment by ileo-cæcostomy and cæcostomy (continued Mr. Handley) had the advantage that it did not subject the patient to the discomfort and loss of nutriment involved in enterostomy, and also usually avoided the necessity of a second operation, for the cæcostomy generally closed spontaneously. But if the patient's condition was very grave, jejunostomy, as a quicker operation, might be preferable.

Hypogastric Peritonitis.

If the treatment described was carried out, the upward spread of peritonitis was almost invariably arrested, but if the obstruction remained unrelieved, the condition began to approximate to the typical general peritonitis described in the text-books. The peritonitis spread upwards to the hypogastric region, the hypogastric muscles became rigid, and the lower part of the abdomen became distended and immobile. The distension had a well-defined upper limit just above the umbilicus; higher still the muscles were not rigid, and still moved slightly with respiration. The vomiting was still gastric, or might have become offensive. The pulse was 120 or 130, and the condition evidently grave, but the extremities were still warm.

Clinical Picture Stage.

If nothing was done, the patient passed, probably within 24 hours, into the "clinical picture" stage, with cold extremities and running pulse. Ileo-cæcostomy and cæcostomy would now be useless, the supra-pelvic ileum being paralysed by the ascending tide of peritonitis, but the condition was still not hopeless, for the abdomen *above the umbilicus* was still free from inflammation. He had tried to improvise a complete emergency alimentary canal above the level of the flood by reopening the abdomen laterally to the umbilicus, and anastomosing the uninflamed transverse colon to a distended but uninflamed coil of jejunum. A temporary exit from the large intestine was then made by tying a tube into the cæcum. The success of this plan had exceeded his hopes, recovery following in three out of four cases.

Discussion.

Sir CUTHBERT WALLACE recalled correspondence on the subject under discussion which had passed between Mr. Handley and himself during the war. The speaker had advocated the methods of treatment described, but without good result; nevertheless, he still might be persuaded of its usefulness. Mr. Handley's treatment was really the treatment of intestinal obstruction; he was going to talk about peritonitis. There were two routes by which patients were killed—the diaphragmatic route and the route of the vessels. The diaphragmatic route was the more dramatic, and had impressed itself upon clinicians. He had seen the surgical treatment of peritonitis from its outset; he himself had once used evisceration and lavage, which had then seemed better than any other method. At present he simply removed or closed the infecting focus and shut up the abdomen; since 1906 he had never drained the latter, and had had no reason to go back on this practice. He laid emphasis on the fact that the peritoneum would kill bacteria, whilst the abdominal wall would fall a victim to them. He considered the surgeon's work to be done when the infective focus was removed.

Mr. **GARNETT WRIGHT** found that the discussion, like all discussions on peritonitis, was limiting itself to appendicitis. General peritonitis, extending from the floor of the pelvis to the diaphragm, was uniformly fatal and seldom met with. Despite modern treatment based on the work of Murphy, the mortality remained high; there was not much further advance till Mr. Handley's paper in 1915, which marked progress not by its description of the pathology of ileus duplex, but by the statement that patients were dying not from toxæmia but from intestinal obstruction. Personally, he believed such obstruction to be due to matting of the bowel. Several times he had separated coils of intestine and had found even when acute sepsis was present that patients recovered; he found the bowel flattened, but evidently not paralysed. They were all familiar with the type of patient who presented symptoms of obstruction outweighing the inflammatory symptoms. The rectus or mid-line incision was preferable to McBurney's incision, and the latter should be abandoned. Mr. Handley had described the operative measures he preferred; he (Mr. Garnett Wright) held that if temporary relief were given the bowel would recover its power. Enterostomy was most valuable when performed early, as soon as the symptoms of obstruction appeared. The aim should be to keep the bowel empty; aperients precipitated the onset of obstruction.

Mr. H. W. **CARSON** felt certain that peritonitis was preventable, and due only to delay in acting upon the diagnosis which ought to be made from the clinical picture. He believed with Mr. Handley that the inflammation spread from one point through the peritoneal cavity; the mortality was directly in proportion to the delay in operating. The treatment of peritonitis occurred before the patient came to the operating table; it occurred at home. The sitting-up position was useful before operation. Nothing should be given by mouth to the patient; if the bowel was loaded an enema, or if empty a saline, should be given, whilst the patient was waiting for the ambulance. He always ordered an enormous fomentation to be applied, going right round the patient's back and reaching down to the pubes. If the lesion was not found the patient would die. He believed in drainage. He made it a rule to operate if there was intestinal pain, whether obstruction was present or not.

Mr. R. P. **ROWLANDS** believed that, in the main, cases of peritonitis did die of intestinal obstruction. About 2500 people died of acute appendicitis every year in England and Wales, mostly through peritonitis. The latter condition was avoidable, but usually the patient did not consult a doctor soon enough, and the doctor did not diagnose the condition in time. The first essential was to remove the focus of infection or to stop the leak. Then the mass of extravasated material must be moved from the abdomen. Speed was almost equally valuable with good work. He did not wash out the peritoneal cavity, but packed it with dry gauze rolls, which could be pulled out entire, leaving the peritoneum dry. He believed in drainage in bad late cases; gauze drainage was to be avoided. Anastomosis between, say, the jejunum and colon did not meet the requirements of the condition, as the lower bowel was badly infected.

Dr. V. Z. **COPE** thought that sufficient distinction had not been made between the different types of peritonitis. He had recently had a case of general suppurative peritonitis starting in the upper abdomen, with no great distension, yet with the same symptoms as those already described. In peritonitis the poison was partly in and partly out of the bowel; the latter was more or less paresed, but not always paralysed. Unless the various ptomaine poisons within the bowel were got rid of, partial obstruction occurred. Mild aperients might be given at first, and stronger aperients after 36 hours; then enemata should be tried, and then cæcostomy or jejunostomy. The contents of the peritoneum outside the bowel should also be dealt with. Vaccines and serums were useful. In severely toxic cases some form of immuno-transfusion might be tried with advantage.

Dr. H. H. **RAYNER** stated that many patients died of acute toxæmia from absorption through the intestinal membranes long before obstruction had time to occur. Death from obstruction took place when nature had limited the field of infection at the onset.

Mr. T. H. C. **BENIANS** spoke of peritoneal immunity and the pathogenicity of *B. coli;* acute toxæmic conditions, he believed, were due to coliform organisms rather than to streptococci.

Mr. **WARREN LOW** thought that the term "general peritonitis" covered an enormous number of diseases; of these, the peritonitis arising from acute appendicitis was the commonest and the most amenable to treatment. He agreed as to the importance of removal of the septic focus, but in a collapsed patient he had left a suppurating appendix in the body and the patient had lived. In cases of distension he had emptied several coils of bowel through an incision and found the procedure useful.

Dr. **SPENCER** believed that the less drainage was employed the better, but that, nevertheless, patients would be killed if the method were never used.

Mr. **SAMPSON HANDLEY** briefly replied.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Nov. 23rd, Mr. R. H. **ANGLIN WHITELOCKE**, the President, being in the chair.

Dr. J. D. **ROLLESTON** showed a specimen of

Hair-Ball of the Stomach.

The specimen was from a girl aged 15—an epileptic idiot who suffered from vomiting and diarrhœa a week before her death. A mass was found in the epigastrium which was thought to be the enlarged right lobe of the liver. At post-mortem the stomach was found to be filled with a collection of hair which formed a complete cast of that organ. On inquiry from the mother it was learned that the patient had been in the habit of eating her hair since she was a baby. Dr. Rolleston reviewed the bibliography of this subject. He considered the X ray appearance so distinctive—the hair-ball appearing a lighter area in the midst of the dark shadow of the bismuth—that a correct diagnosis should now be the rule instead of the exception.

Mr. H. A. T. **FAIRBANK** showed a photograph of a hair-ball removed from the ileum of a girl, aged 8 years, whose symptoms resembled those of partial obstruction.

Dr. W. E. **ROBINSON** showed a case of

Lymphangioma of the Foot

in a child aged 7 months. The foot was noticed to be growing larger, especially in the region of the metatarsal bones and terminal phalanges. The X ray, however, showed the bones to be perfectly normal. He asked for suggestions as to treatment.—Mr. C. MAX

PAGE suggested that a Syme's amputation appeared to be the most rational surgical treatment for this case.—Mr. **FAIRBANK** suggested that the diagnosis should be that of hypertrophy of the foot, and agreed with Mr. Max Page as to treatment.

Dr. A. **BENJAMIN** showed a case of

Precocious Puberty

for Dr. R. Hutchison. The child, now aged 3½ years, commenced menstruation at the age of 17 months, and had continued menstruating at more or less regular intervals of one month up to the present date. The breasts were well formed, and hair was present on the pubic region. Her weight and height were that of a child of 8 years. Mentally she was normal for a child of her age, but had fits of bad temper. The carpal bones were ossified. He placed this case, by a process of exclusion, amongst those due to ovarian hypersecretion, although under an anæsthetic no definite evidence of this could be obtained.—Dr. **PARKES WEBER** agreed with this diagnosis.

Dr. C. C. **WORSTER-DROUGHT** showed a case of

Progressive Neural Muscular Atrophy

(peroneal or Charcot—Marie-Tooth type), in which the upper limbs were also affected. The patient, aged 13, was one of a family of three, the other two not being affected. After the age of 2½ it was noticed that she turned her toes in and tended to fall down when she walked. During the past four years her feet had become more deformed and the hands and arms had wasted considerably. Her present condition was thin and nervous, and she constantly wriggled her feet and legs. There was a tendency to bilateral main-en-griffe with marked wasting of the small muscles of the hand. The lower extremities showed pronounced talipes equino-varus of both feet with wasting of the peronei. The electrical reactions were given in detail. Dr. Worster-Drought stated that it was difficult to draw a hard-and-fast line between certain neural atrophies, nuclear atrophies, and muscular dystrophies.—Dr. E. W. **NEILL HOBHOUSE** gave the details of a similar but less marked case. The remarkable feature of his case was that one femur was smaller than the other. He asked if such an abnormality had been previously noted.

Dr. **NORAH SCHUSTER** and Dr. **DONALD PATERSON** showed a specimen from a case of

Paroxysmal Tachycardia,

in an infant aged 9 weeks. The specimen was the heart from a female child, who had been admitted to the Infants Hospital, Vincent-square, for blueness and shortness of breath since birth. The infant weighed 8 lb. When first seen it was wasted, feeble, and cyanosed, with a pulse of 200 per minute. The heart seemed enlarged, so also the liver. During the two days in hospital before death there were four definite paroxysmal attacks, lasting about ten minutes each, during which the infant had marked dyspnœa and cyanosis, and was in obvious distress. The pulse at these periods became uncountable, afterwards falling as low as 140. Digitalis had no effect. At post-mortem a patent inter-ventricular septum, patent foramen ovale, and patent ductus arteriosus were found. The pulmonary artery arose from the left ventricle and the aorta from the right ventricle. Microscopically the heart muscle showed degeneration with intercellular fibrosis.—Dr. **GEORGE SUTHERLAND** considered this a very rare case, and cited a similar case of paroxysms of tachycardia, which had been mistaken for "petit mal."—Dr. **WEBER** suggested that the cases reported in French literature under the heading of paroxysmal cyanosis were similar to this case.—Dr. **PATERSON** agreed that the reported cases were very few, but considered that attacks of blueness with rapid breathing were not uncommon in children with congenital heart disease. He wondered how many of these might be cases similar to the one reported should they be as closely observed as this one had been. It was only by having the pulse charted hourly, and specially taken during attacks, that the condition could be diagnosed.

LIVERPOOL MEDICAL INSTITUTION.

A MEETING was held on Nov. 15th, with Dr. J. **HILL ABRAM**, the President, in the chair.

Dr. **HENRY COHEN** read a note on the

Value of Hypertonic and Hypotonic Saline Solutions in Cerebral Conditions.

After a brief résumé of the experimental evidence on which this therapeutic method is based, he recorded ten cases, six of cerebral tumour and four of post-operative cerebral hernia, in which marked alleviation of symptoms followed intravenous injection of 20 c.cm. of 30 per cent. sodium chloride solution. He commented on the oral administration of salt in these conditions, and on the use of hypertonic salines in the meningismus of acute infections, prior to cerebral operations, in the diagnosis of extracranial from intracranial causes of headache, and in the prevention of foraminal crowding following lumbar puncture in cases of cerebral tumour. The value of hypotonic salines in post-puncture headache was also recorded.—In replying to the discussion, Dr. Cohen pointed out that a considerable amount of experimental work was yet to be done, and suggested that ophthalmic surgeons should try these hypertonic salines in cases of increasing intra-ocular tension.

Mr. W. A. **THOMPSON** read a note on

Renal Sarcoma of the Kidney in an Infant.

The patient was a female child, aged 15 months, who was anæmic, emaciated, and had a large semi-solid swelling in the left lower abdomen. This swelling had been noticed for six months. It was moderately smooth in outline, there was no notch, there were dullness and bulging in the loin with colon resonance in front. The urine was normal, and had apparently always been so. A renal sarcoma was diagnosed and operation advised. The operation was carried out through an incision to the outer side of the left rectus. The peritoneum on the outer side of the descending colon having been incised and its edges brought up to the skin incision, the operation was completed retroperitoneally. The child left hospital ten days later in excellent health. Mr. Thompson said that this condition appeared mainly during the first seven years of life, both sexes were affected with equal frequency, and the right side as often as the left; occasionally it was bi-lateral. The clinical features in all cases were few and uniform—a progressive, painless swelling in the lower abdomen soon associated with an increasing constipation, and ultimately accompanied by emaciation. The condition was thought to be a sarcoma arising from the intrarenal adenomatous tissue which should have formed the convoluted tubules, but which, because of a poor blood-supply, failed to develop normally, and had taken on a tubulo-acinar formation. This had become sarcomatous, and the growth, obliterating the calyces and renal pelvis, prevented secretion from the affected organ, and thus explained the absence of hæmaturia, which absence was such a common feature in these cases. The operative mortality was high, and of the late cases the majority of those who survived operation rarely lived 12 months. This case made excellent progress for almost four months, when the patient contracted measles and died.

Dr. A. **DINGWALL FORDYCE** and Dr. **NORMAN CAPON** communicated a paper on

"Idiopathic" Hypertrophy of the Bladder.

Two cases of this condition were described and lantern slides of the pathological condition exhibited. The analogy with other apparently idiopathic neuromuscular conditions was dwelt upon, and reference made to the literature on the subject. At the post-mortem examination the only pathological findings were hypertrophy and dilatation of the bladder, dilatation of the ureters and of the pelves of the kidneys, and cystic-like degeneration of the kidneys. There was no detectible cause producing the obstruction. The inference, corroborated by analogy, was that vesical spasm produced the local sequelæ, and that it in turn was secondary sometimes to obvious nervous lesions and sometimes to nervous abnormalities which were not detected.—Mr. R. E. **Kelly** pointed out that the post-mortem picture of dilated bladder, dilated ureters, and dilated renal pelves showed a remarkable similarity to the condition found in adults with an enlarged prostate or a stricture of the urethra. The disease was limited to the male sex, and therefore the explanation that it was due to some neuropathic cause was a difficult explanation to accept. In his opinion there was obstruction. This obstruction was due to the constant and repeated blockings of the urethra by plugs of mucus. One had only to witness the pain, tenesmus, and straining in the living subject, followed not by a complete emptying of the bladder, but the passage of a small plug of mucus, to appreciate the enormous strain on the bladder. The increased tension inside the bladder produced the disease. It was a further example of the value of living pathology over observations made in the post-mortem room. In one case he had to withdraw a catheter two or three times, and remove a plug of mucus from the eye of the catheter before he was able completely to empty the bladder. For this reason it was found impossible to wash out the bladder per urethram, for even after repeated washings under an anæsthetic mucus could still be detected by the cystoscope. In his opinion suprapubic cystotomy was the best treatment.

ULSTER MEDICAL SOCIETY.

At a meeting of this Society, held on Nov. 8th, with Prof. W. St. C. **Symmers**, the President, in the chair, a discussion took place on

Insulin in Diabetes Mellitus.

Dr. **John Milroy** made a few introductory remarks on recent developments in the physiology of the internal secretion of the pancreas, especially in their relation to treatment.

Clinical Results.

Dr. **Sinclair Miller** (Harrogate) spoke on some clinical results with the use of insulin in diabetes mellitus, in which he showed that insulin was a potent remedy in the treatment of this disease. The tedious period of preliminary starvation was no longer necessary and the patient was more rapidly relieved of his distressing symptoms. Within a short period of 24 to 48 hours the blood-sugar of a severe diabetic could be brought down to normal, and in a few days the patient began to feel the benefit of the treatment. The regulation of the diet was as essential as ever, or even more so. Insulin must be given by hypodermic injection as it was rapidly destroyed in the alimentary canal. Recently a method of inunction had been suggested, and it had been shown that insulin given in large doses by the mouth in an alcoholic solution had some effect. The successful treatment of diabetes with the aid of insulin called for the observance of the usual precautions—viz., the eradication of all foci of infection, the accurate control of diet, the maintenance of a normal blood-sugar percentage, the avoidance of over-nutrition, extreme under-nutrition, mental worries, over-exertion, infections, chills, &c., and a life consistent with the diet restrictions. Insulin and dietetic restrictions were unnecessary in renal glycosuria. In cases of glycosuria dependent on cancer of the pancreas or cerebral lesions no benefit could be expected from insulin.

The general practitioner might use insulin with hope of success, provided he had mastered the principles of diet, and had experience of the use of insulin, and that an occasional blood-sugar estimation could be carried out. Starting with small doses, say 5 units twice daily, the dose should be gradually increased until the urine became sugar-free. Severe cases, however, should be placed in a dietetic institution or hospital, and their treatment should last from four to six weeks. An initial fast accelerated the patient's progress. The patient should then be placed upon a diet calculated by allowing about 12 calories to each pound of body-weight, the protein being about half a grain per pound of body-weight, and the carbohydrate at first limited to 20 gr. The fat must be high to make up the proposed total of calories. The ultimate scale of dosage could only be arrived at slowly and by trial. Two injections could be given conveniently, the first half an hour before breakfast, and the other half an hour before the evening meal. If possible, the major portion of the carbohydrate allowed should be divided equally between these two meals. It was more important that food be taken after insulin than that insulin be given before food. After a few days on the basal diet and when the blood-sugar percentage had reached a satisfactory level the diet might be increased and the insulin decreased according to the needs of the patient. Instruction regarding diet and the mode of administering insulin must be given. Over-dosage of insulin produced flushing of the face, followed by pallor, sweating, sometimes faintness, a feeling of extreme hunger, a sense of apprehension, tremors, loss of the finer movements, and ultimately in some cases unconsciousness. There was little risk from hypoglycosuria in institutional treatment, but when the patient was in his own home he should be warned regarding the symptoms and instructed in their treatment, which consisted in administering 1 to 2 oz. of sugar in hot water by the mouth, and in case of unconsciousness an intravenous injection of about 100–200 c.cm. of a 10 or 20 per cent. solution of glucose. One c.cm. of 1 in 1000 adrenalin or 1 c.cm. of pituitrin might be effective in restoring consciousness.

The symptoms of over-dosage by insulin arose at very different levels of the blood-sugar percentage, but generally these symptoms occurred only when the blood-sugar fell below 0·08 per cent. Elderly patients might have a blood-sugar level far above the normal range and yet the urine might be sugar-free. The blood-sugar level was a safer index for treatment than glycosuria. It would seem that the continuous treatment of diabetes by insulin was necessary and the cost was heavy. It might run from £30 per annum in a mild case to £150 per annum in a severe case. In diabetic coma in the early stage insulin was almost a specific. The patient must be given a large dose, 60 units or more intravenously in moderate or severe cases. In milder cases hypodermic injections might be effective. Accompanying the administration of insulin 500 c.cm. of a 10 per cent. solution of glucose should be given. If there was any fear that the alkali reserve was low, 1 to 1½ oz. of sod. bicarbonate should be given. Coma was the result of ketosis, rather than of hyperglycæmia. Insulin assisted in the destruction of the ketone bodies as much as in the reduction of the blood-sugar level. Hence, glucose was given to prevent the risk of hypoglycæmia, and at the same time to supply an easily available source of fuel for the destruction of the ketone bodies. The speaker read notes of a series of illustrative cases.

Dr. J. A. **Smyth** gave the results obtained in the treatment of 50 cases of diabetes mellitus with insulin at the Royal Victoria Hospital, Belfast. He dealt first with the definite diagnosis of the disease, especial reference being made to the use of glucose tolerance curves. In this connexion an account was given of two interesting cases of glycosuria recently seen—one due to injury of the pituitary body caused by fracture of the base of the skull, and the other due to a chronic cholangitis and hepatitis following on a gastrojejunostomy. The treatment of diabetic coma as carried out at the hospital was described in detail, from the borderline cases to those which had been completely comatose for 24 to 36 hours. No case of coma had been lost. Of the cases of ordinary diabetes some had done exceedingly well, most had done well, but one or two had responded only to a limited extent. A detailed account was given of a few cases which presented especially interesting features. In many of them it was possible to demonstrate a greater or less degree of recovery of function of the islet tissue in the course of treatment allowing of a steady increase of carbohydrate in the diet, or a diminution of the amount of insulin.

Reviews and Notices of Books.

CARDIOLOGY.

Principles of Diagnosis and Treatment in Heart Affections. Second edition. By Sir James Mackenzie, M.D., F.R.S., LL.D. Aberd. and Edin., F.R.C.P.I. (Hon.), Director, St. Andrews Institute for Clinical Research; and James Orr, M.B., Ch.B., Physician to the Institute. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 247. 7*s.* 6*d.*

In the second edition of his popular small book on the heart Sir James Mackenzie has been assisted by Dr. James Orr. The book presents afresh the well-known features of the first edition; the subject-matter has been rearranged and one or two new paragraphs have been added. There is one small point in the chapter on heart attacks which calls for comment. The author uses the term "palpitation" to describe the condition more commonly known as "simple tachycardia." As palpitation is generally understood to mean consciousness of the heart's action and may be one of the most troublesome symptoms in paroxysmal tachycardia, the special use of the word is liable to lead to confusion. A critical review of the more recent researches on auricular fibrillation and flutter from the pen of so distinguished a pioneer in the investigation of the cardiac arrhythmias would have been very welcome, but in a book of this size and scope it is probably wise to exclude matter which is still at a controversial stage. We do not doubt that the second edition will achieve as much well-deserved popularity as was enjoyed by the first edition.

Heart Records, Their Interpretation and Preparation. By S. Calvin Smith, M.S., M.D. Philadelphia: F. A. Davis Company. 1923. Pp. 313. $7.00.

In the preface to his book Dr. Calvin Smith states that it is intended to be an "elementary guide" for those who wish to study graphic methods. He deals not only with the physiological basis and the interpretation of records, but also devotes several chapters to the various details of technique. The greater part of the book is concerned with electrocardiography, and the last two chapters refer to polygraphy and graphic methods in general. A highly technical subject such as electrocardiography may be approached from one of two aspects, either from that of the general physician, or from that of the specialist; and in endeavouring to meet the requirements of both parties the author has had difficulty in coming to a satisfactory compromise. The general physician wants to learn how to interpret records, and to know the extent to which electrocardiography is capable of helping him in the diagnosis, prognosis, and treatment of his cases. He does not want to read about the details of technique, nor the various troubles which the laboratory worker is liable to encounter. The specialist, on the other hand, must make himself master of his technique, and cannot do so without possessing an elementary practical knowledge of physics, such as can only be acquired in the laboratory. To the novice Dr. Calvin Smith's book would be somewhat disheartening, for the author's ingenuity has enabled him to compile a truly remarkable list of possible mishaps and mechanical troubles to which the electrocardiographic method is susceptible. He appears hardly to have given his readers credit for the average amount of common sense. This faculty alone should be sufficient to prevent such mistakes as connecting the right-hand wire to the left-hand electrode, or mounting records upside down. Again, the young cardiologist who ventures to arrive at a complete clinical diagnosis by the use of graphic methods alone requires to be instructed in the general principles of medicine rather than cardiology; nor does the operator who gets into trouble through allowing "meddlesome persons" to tamper with his instrument deserve much sympathy. The chapter dealing with photographic technique appears to be somewhat superfluous for the average laboratory worker of the present day, and the book as a whole would be improved by being considerably shortened.

The "Nauheim" Treatment of Diseases of the Heart and Vessels in England. Sixth edition. By Leslie Thorne Thorne, M.D., B.S. Durh., M.R.C.S., L.R.C.P. Lond. London: Baillière, Tindall and Cox. 1923. Pp. 232. 7*s.* 6*d.*

In this book Dr. Thorne Thorne gives a detailed description of the special therapeutic measures employed, and discusses the benefit which may accrue from this line of treatment in various diseases. The author's particular thesis is, that the treatment can be given anywhere where there is a bathroom and a good supply of hot water, with results as successful as those obtained at Nauheim. Thus home treatment in England is available for many patients who would be physically incapable of undertaking the journey to one of the continental spas. So far as this part of his argument is concerned most physicians will be prepared to agree with Dr. Thorne, but when he comes to deal with the mechanism whereby the beneficial effects are obtained, he leads his readers on to much more debatable ground. Therapeutic deductions regarding even empirical treatment are beset with innumerable difficulties, and to attempt to go further, and to explain the mechanism of treatment on rational lines, is to enter a field where hypothesis requires to be supported by very detailed and conclusive evidence. That the "Nauheim" treatment does produce beneficial results in certain selected cases of cardiovascular disease few will doubt, but to assess the respective values of the different factors by which these results are produced is no easy matter. The influence of mind over body has received so much attention in recent years that some may be tempted to think that the pendulum has swung too far; but that there is an important psychological factor in spa treatment is unquestionable. Again, the carefully regulated routine to which the patient is subjected during a course of treatment is undoubtedly of considerable importance. Dr. Thorne appears to over-emphasise the therapeutic value of the baths themselves, and the evidence which he brings forward in order to prove his point is not convincing. For example, it is difficult to believe his statement that "a change of one degree in the temperature of the water, or a shortening or lengthening by one minute of the time of immersion . . . will often materially affect the result."

OPHTHALMIC SURGERY.

A Handbook of the Surgical Operations on the Eyeball and its Appendages as Practised at the I. Eye Clinic, University of Vienna. By Dr. Josef Meller, Clinical Professor of Ophthalmology. Edited by Dr. William M. Sweet, Clinical Professor of Ophthalmology, Jefferson Medical College, Philadelphia. Third edition, translated from the second (German) edition. London: William Heinemann. 1923. With 219 original illustrations. Pp. 365. 25*s.*

Two methods of writing a text-book on any branch of surgery are possible. One is to give some account of all the operations which are or have been habitually practised, the other to select those which the author considers the operations of election, and describe them in sufficient detail to be a real help. The latter is the method of Dr. Meller.

The Vienna methods of operating are very much the same as those practised in London by surgeons who are moderately conservative, and the descriptions in this book and the excellent illustrations will be found useful by the young operator. The first operation described is excision of the lacrymal sac; 12 excellent figures materially assist the understanding of the letterpress. The importance of a careful study of this operation is great, as it is so often done incompletely with unsatisfactory results, a fact which accounts for the introduction of the alternative intranasal operations. These are only briefly referred to. Next we have 90 pages devoted to lid operations. The use of skin flaps is well illustrated. For ptosis the operations described are that of Hess and that of Motais, probably the two which are most generally practised in this country. After a chapter on squint operations, enucleation of the eye under local anæsthesia is described. It appears that in Vienna a general anæsthetic is only used in the minority of cases. Krönlein's resection of the outer orbital wall is an operation for which many ophthalmic surgeons would call in the general surgeon, but the description in this book is no less serviceable on that account. A very detailed description of the ordinary (i.e., extracapsular) operation for the extraction of cataract is given. The only part of it which appears unusual is the position of the operator. It is the custom at Vienna to sit at the right of the patient who is lying on the operating table. The incision is made on the right eye with the left hand, on the left eye with the right hand. There is no mention of "washing out" the soft lens matter, even after the operation of linear extraction in young adults, so that presumably this process is not practised in Vienna. There is no mention either of Smith's intracapsular operation or of Barraquer's. This conservative tendency is also manifest in what the author says of sclero-corneal trephining for glaucoma—viz., that it would appear to be justified only in those cases of glaucoma in which the ordinary iridectomy cannot be performed without extreme difficulty or danger. Because of the possibility of late infection, the operation, he says, is not indicated in young persons or if the patient has only one eye.

While not in agreement with everything contained in this book, we can thoroughly recommend it as a good and clear account of the operative surgery of the eye from a teacher of high reputation. The illustrations are an important, indeed an essential, part of the book.

LIGHT AND COLOUR.

By R. A. Houstoun, M.A., Ph.D., D.Sc., Lecturer on Physical Optics in the University of Glasgow. London: Longmans, Green and Co. 1923. Pp. 179. 7*s.* 6*d.*

Dr. Houstoun has written a very interesting book on light and colour. It is unusual, savouring neither of the text-book nor of that which merely seeks to catch the fancy, though dealing with those aspects of light and colour in which most popular interest is taken at present. How wide a variety these interests include is seen by a glance at the titles of the 11 chapters of the book. Dr. Houstoun wisely does not restrict this treatment to visible radiation; when occasion requires he initiates his readers into the characteristics of other parts of the electro-magnetic spectrum. The chapters on colour photography, colour-blindness, and the light of the future are essentially practical in their treatment. The last chapter is devoted to the psychology of colour, and will be to many a revelation of the effects which different colours may have upon the human subject, not so much perhaps upon body processes as upon the mental ones.

The book is well illustrated; the treatment of the subject is excellent throughout, and a very wide field of interest is covered without elaboration of detail.

BIOCHEMISTRY.

Handbuch der Biochemie des Menschen und der Tiere. Second edition. By many authors, under the general editorship of Prof. Dr. Phil. et Med. Carl Oppenheimer, in Munchen. Jena: Gustav Fischer. 1923. Parts 1 to 7. 4 to 7 pre-war marks each.

Here we have seven discontinuous paper-backed parts of a symposium. Lieferung 1 stops in the middle of a sentence dealing with the pure chemistry of animal fats, whilst Lieferung 2 deals with the gases in the body. This may not be avoidable in the production of a large work of this nature, but it makes comment difficult. The work is to be completed in nine volumes which are to cover the whole field of animal and human biochemistry, the whole subject being treated more from the biological than the purely chemical standpoint. Only a comparatively small section is to be devoted to the pure chemistry of proteins, fats, and carbohydrates. This is a great advantage since the work does not in any way overlap such systems as Abderhalden's "Handlexikon," which is devoted entirely to the pure chemistry of natural products and their physiological properties. Each section is written by an authority and has been brought quite up to date. A series of references is appended to each chapter, and seems remarkably complete. It is impossible to enter upon a detailed review until more sections are completed. The first seven parts are uniformly good, and it is quite safe to say that, if this edition continues in the same manner that it has begun, it will become indispensable to anyone working in the subject.

JOURNALS.

Journal of Industrial Hygiene.—In the September issue H. L. Blumgart reports an investigation made to ascertain whether lead dust deposited in the upper air-passages is absorbed into the body. The experiments were carefully carried out on animals. White lead was sprayed intra-nasally after the œsophagus had been ligatured and a tracheal cannula had been inserted. The animals were kept alive for 24 to 36 hours. In every case lead was found throughout the tissues of the body, showing that it is absorbed from the upper air-passages rapidly and in excess of a minimal toxic dose. The conclusion is drawn that in industry lead dust may be absorbed intra-nasally. —Further observations on tetrachlorethane poisoning by D. C. Parmenter lead to the conclusion that persons exposed to the vapour of this substance show a definite blood picture and gastric symptoms easily recognised. He therefore considers that, provided proper precautions are taken and medical supervision enacted, tetrachlorethane can be used safely in industry.—A report appears upon an extensive investigation into the use of electric precipitation for quantitative determinations of dust in the air. The apparatus and methods employed are fully described. While electric precipitation of dust for this purpose has certain objections, nevertheless the method offers an efficient way of determining the dust particles present.——In the October issue an article by J. S. Sheppard deals with the employment of cardiac patients effected through an employment bureau. The result of regular work on this type of patient was found excellent, and his work tolerance was much greater than was expected before placements in regular industries were made and watched. The experience is held to justify the statement that well selected work will frequently help cardiac patients to improve and go from Class II. B to A, and that work in normal surroundings has a much better effect than work in segregation.—An investigation made in a glass bottle industry by J. P. Baumberger and E. E. Perry is of interest because they found that judgment of size of gobs of glass was dependent on Weber's law—i.e., that a certain percentage increase in the size of stimulus is necessary before the sensation of appreciable increase in size arises. The investigators suggest that in many cases in industry the limits of accuracy to be expected of workers could be determined on the basis of this law.—The most important contribution is one from B. S. Nicholson, who deals with the pathology and clinical aspect of silicosis and pulmonary tuberculosis. This article is the result of careful clinical observation while carrying out work under the Workmen's Compensation (Silicosis) Act, 1918. The author concludes that more persons than is generally thought die from silicosis without becoming tuberculous. He puts forward the suggestion that when tuberculosis is manifested the infection may have occurred when the dust particles were originally inhaled and have remained latent within a centre of silicotic fibrosis until a breakdown of scar tissue releases it, perhaps years later, to subject the tissues to a massive infection

THE LANCET.

LONDON: SATURDAY, DECEMBER 1, 1923.

THE GENERAL MEDICAL COUNCIL.

THE opening of the 118th session of the General Medical Council on Tuesday last, Nov. 27th, was presided over by Sir DONALD MACALISTER, whose devotion to duty must entail considerable personal sacrifice and whose recovery from his recent illness is a matter of great and common congratulation. The address from the chair, which was briefer than usual, took particular note of the position of the medical profession in India, where the conditions for the recognition of Indian medical degrees upon the British Register are attended with difficult and delicate circumstances. The Government has, however, placed Lieut.-Colonel B. A. NEEDHAM, I.M.S., on appointment by the Indian Government and with the approval of the General Medical Council as official inspector of Indian universities and colleges, on special duty in order that he may attend the meetings of the Executive Committee of the Council at this session to discuss all the questions. As Sir DONALD MACALISTER pointed out, and as is too often forgotten, there are two sides to these, as they refer to practice in India or practice in Great Britain. While as far as the first category is concerned the Empire of India may be considered autonomous, as regards qualifications for registration in this country Acts of Parliament compel inquiry into the qualifications for practice. Difficulties will arise, and have arisen, which are not readily capable of solution, and we are glad that the Council, owing to the valuable intervention of Sir NORMAN WALKER, will be able to obtain first-hand advice from Colonel NEEDHAM.

Most of the time of this session will be occupied in hearing cases of discipline under Section 29 of the Medical Act, 1858, and after the President's address the business of the Council was directed immediately to the hearing of these cases.

◆

THE SUPPLY OF NURSES.

SOME three years ago Mr. E. W. MORRIS, house governor of the London Hospital, pleaded[1] for a thorough investigation of the reasons why women were not entering the nursing profession in sufficient numbers. The shortage of probationers of a type acceptable to matrons of hospitals still remains acute, and though in this country no steps have yet been taken to organise such an inquiry, the problem has been tackled with considerable skill and understanding in America by a committee appointed by the Rockefeller Foundation. The main outcome of the labours of this committee, a section of whose report we summarise on p. 1203 of this issue of THE LANCET, is their conviction that little improvement will result until the conflict is recognised and to some extent resolved, which at present exists between two of the functions of a modern hospital—viz., that of economic hospital administration, which aims at caring for the sick at minimum cost, and that of catering adequately for the educational requirements of nurses. No one who studies carefully the documented evidence on which this conclusion is based can doubt its truth. Among the constructive suggestions to which it gives rise are: (1) That training schools should be under the direction of a board organised for the primary purpose of education, and (2) that adequate funds should be available not only for the educational expenses of the school itself, but also for the replacement of student nurses by graduate nurses and hospital help in the execution of routine duties of a non-educational character. It is idle for hospital administrators and senior members of the nursing profession to regret the days when nursing made a strong appeal to the highly-bred educated woman, who adopted it as a pious vocation rather than as a profession. These days will not return. The sane young woman of to-day differentiates clearly between her desire to serve the community and the need first to equip herself speedily and adequately to do so. Since many professions giving opportunities of service are now open to her, factors in her choice will, doubtless, include conditions of training which are not unnecessarily strenuous or autocratic, as well as prospects of reasonable remuneration, status, and employment when training is complete. While the difficulties of the authorities responsible for staffing hospitals with probationers of a type most likely to develop into reliable staff nurses and sisters receive universal sympathy, the point of view of other interested parties—the medical practitioner, the patient, and the nurse herself—have not always been treated with the same respectful consideration. May it not be that the leaders of the nursing profession have ideals for its development which rise above the effective demand of the average practitioner and patient, and moreover require a degree of intellectual ability which will not be satisfied by the conditions of work open to any but the very few?

This is a view which has influential medical backing. Among the Collected Papers of the Mayo Clinic for 1921[2] is a report of an address by Dr. C. H. MAYO to a hospital conference, in which he sharply criticised the conditions of training of the hospital nurse in this sense. He complained that the nurse who, having achieved a high standard of general education, has laboured diligently in hospital for three years, emerges overtrained as a nurse and undertrained as a physician. He contended that the requirements are too high for the average work demanded of the nurse after registration, holding that they should on the one hand be raised for those who are capable of acting as responsible technical assistants or specialists in various branches of nursing, and on the other hand that the period of compulsory training should be made shorter in conformity with requirements for general nursing. He suggested the reduction of the course of training to two years, with a third year of post-graduate study, which should be optional. This extra year should not necessarily follow directly on the early training, but those who wished to do so might be allowed to return to hospital at any time to qualify for higher service. "Chief nurse in the hospital, chief surgical nurse, nurse in dressing service, anæsthetist, county, city, and school nurse, industrial and child welfare nurse, dentist's aid, physician's aid, and laboratory technician" are among the positions suggested for those who have completed the advanced course.

The dual difficulty has received attention from the Rockefeller committee, who recognise it by the suggestion, which is more likely to find acceptance than that put forward by Dr. Mayo, of the formation of a subsidiary nursing service. To those who refuse to admit the need of any reduction in the standards required of one expected to attend to the sick, it may be pointed out that though we cannot fight disease with an army of privates, neither do we need an army of generals. That the distinction should be in the nature of the work undertaken rather than on economic lines will doubtless make the proposal less unpalatable to the nursing profession, which has not hitherto looked kindly on any suggestions of grading. As we pointed out last week in connexion with the establishment of convalescent hospitals for the double purpose of pre-hospital and post-hospital care, attention to an invalid who is not ill enough to be interesting is apt soon to become irksome. The boredom of the experienced nurse in charge of a chronic case, and her desire to leave such a post for one in which her technique has more scope, is an obvious corollary of the development of nursing education, but the wants of the subacute or chronic case are likely to suffer in the future unless some sort of subsidiary nurses are available. For these patients the economic question also is a serious one, in proportion as their illness is protracted. The letter which we print on p. 1220 gives expression to still another side of the difficulty. The problem here is the provision of nursing service which combines the minimum efficiency demanded by the doctor and the maximum remuneration in the way of accommodation and standards of comfort, as well as fees, that can be afforded by the patient. We trust, therefore, that serious consideration will be given to the section of the report which attempts to meet this need, as well as to that on the training of hospital nurses.

PUBLIC HEALTH AND THE ROCKEFELLER FOUNDATION.

Out of the Rockefeller Sanitary Organisation for the Eradication of Hookworm Disease—planned and matured in the mind of Mr. John D. Rockefeller in 1909—there has grown the International Health Board of the Rockefeller Foundation, and before us we have the ninth annual report, covering the period from January to December, 1922.[1] With such success was the original plan carried out—involving a geographical survey of the distribution and intensity of the disease in the United States, the cure of its sufferers, and removal of the source of infection by avoidance of soil pollution—that in 1914 the chief purpose of this first Sanitary Commission may be deemed to have been accomplished. The success was such that in 1913 a permanent institution on a wider basis, the Rockefeller Foundation, was endowed by its founder with 100 million dollars. In the course of ten years of coöperative service, hookworm infection the world over has been measurably diminished, progress has been made towards reducing the ravages of malaria, and a relentless campaign is still being waged against yellow fever wherever its danger-flag appears.

From the outset it was fully recognised by the Rockefeller Foundation that public health is essentially a function of government, and that continued advance in preventive medicine throughout the world depends upon an adequate supply of skilled public servants. To further the investigation of epidemic diseases, the Foundation has promoted training schools for health officers, nurses, and visitors, and contributions were made towards the establishment of schools of public hygiene. With regard to the conquest of yellow fever, it is remarked that "no other infectious disease has been so completely subjected to human control as yellow fever, since the day when stegomyia was found to be its intermediate host." The epidemic of 1920, with about 20,000 cases in its train, was conquered in Peru by 1921.

An interesting map is given of the retreat of yellow fever in 1900–1922 in the Western Hemisphere. There must, however, be no relaxation of vigilance. Equally satisfactory results were obtained in British Honduras, Mexico, Guatemala, and Ecuador as the result of unceasing efforts to eradicate stegomyia. The means adopted and the successes gained in combating malaria "at home" are described. Abroad the fight has been taken up, in response to official invitations, in Italy, where malaria is the outstanding health problem of the country, for, as the report concisely puts it, "with approximately 2,000,000 cases a year, the disease is not only a vital factor in the life and health of Italy, but a matter of serious concern on the economic side as well." In the anopheles belt all the conditions favourable to the breeding of a singularly virulent and hardy type of mosquito (*Anopheles maculipennis*) exist, while unfavourable housing conditions, and the migratory character of agricultural labour, all conspire to create a problem of the first magnitude. It was decided to send a representative to Italy during 1923 to make a survey. The Board is also coöperating with the Government of Palestine in the investigation of various malaria problems in that country. A campaign against tuberculosis has been conducted in France since 1917. At the end of 1922 there were 421 dispensaries at work, of which 301 were created on the initiative and with the coöperation of the Board. An educational campaign was also conducted on a national scale, practically the entire administration of which is now in French hands.

As an object-lesson of the value of public health work no better example can be given than the splendid achievements in the control of hookworm disease—a menace which threatens more than half the world, for 900,000,000 people live in the areas of infection. This menace can only be dispelled by spreading knowledge of the disastrous consequences of the disease and by instructing the people in the elementary practice of hygienic living. The gratifying results already obtained, and the further measures taken to exterminate the disease in Columbia, Paraguay, the West Indies, Central America, and the Far East, are recorded in the report. A survey is now proposed for Spain on the invitation of the Spanish Government. Encouragement as well as monetary assistance has been given liberally for public health agencies both in the United States and abroad; more especially in Brazil, where also a public health nursing service is being created. Not the least of the Board's successful efforts has been the development of public health laboratories in the Western Hemisphere and its coöperation with the League of Nations in the coördination of efforts against disease. Moreover, by way of broadening the base of health work by education, the Board in the past few years has aided in establishing the Johns Hopkins School of Hygiene and Public Health, the Harvard School of Public Health, the Institute of Hygiene at São Paulo, Brazil. In the Old World the Board has given help to a similar Institute at Prague, and one at Warsaw, as well as contributing more than 2,000,000 dollars towards the School of Hygiene in London, the plans for which are just beginning to take shape. Further, as public health services cannot be created by the supply of funds alone, and in order to aid in the development of leaders in the field of public health, Fellowships have been granted to carefully-chosen individuals. Seventy-nine men and women from 19 countries throughout the world have been thus appointed to carry out research in public health work. Some of these have left our own medical schools within the last few weeks, and their future work is a matter of keen interest on this side of the Atlantic.

THE ANCIENTRY OF MEDICAL ETHICS.

THE duty of the medical man towards his patient, his fellow practitioners, and himself has always been a matter of consideration, whether approached from the purely professional side or from that of the law; and if there exists no definite printed system of medical ethics to indicate conduct within the profession, it is because nothing more definite can be said than was said some 2000 years ago on an Eastern hillside. The code on which we act is founded mainly upon tradition for its details, but in spirit it relies wholely on the dictum that a man should do as he would be done by. It is useful to have recalled to our minds one of the best published codes of ethics in the English tongue—namely, the code drawn up by Dr. Thomas Percival, 1740–1804, of Manchester, wherein this spirit is fully recognised. Percival's work on medical ethics was first published in 1803, and is now known to few. However, Dr. CHAUNCEY D. LEAKE, of Madison, Wisconsin, has written an excellent little pamphlet[1] on the subject, giving a life of Percival and reprinting the code, the discourse on hospital duties being omitted on account of its length. Percival's career is set out at length in the Dictionary of National Biography. He was born at Warrington in 1740, studied medicine at Edinburgh, was made an F.R.S. in 1765, "because of his mathematical and philosophical learning," established himself in Manchester in 1767, and in 1778 was appointed physician to the Manchester Infirmary. It is interesting to note that he was among the first to call attention to the evils of the factory system, and especially to the abominable conditions of child labour. His code of ethics served as the model of that adopted in the United States, especially that put forth by the American Medical Association. Percival, of course, was not the first to formulate a code of medical ethics, as Dr. LEAKE records in his introduction. It is unnecessary to do more than mention the code of Hammurabi, the Hippocratic oath, and the regulations of Frederic II., A.D. 1224, while we may add to the instances given by Dr. LEAKE the advice laid down by Arnold of Villanova, Henry of Mondeville, Lanfranc, William of Salicet, and John Arderne a little later.

Percival's code, as given by Dr. LEAKE, is in four chapters. The first deals with professional conduct relative to hospitals and other medical charities, the second with that in private or general practice, the third with the conduct of physicians towards apothecaries, and the fourth with professional duties in certain cases which require a knowledge of the law. The code is in every way admirable, and may be studied with advantage by medical men to-day, although Section No. 3, dealing with apothecaries, is of course out of date; the apothecary whose services our grandfathers spoke of as "using the 'potticary'" has passed away, except in so far as some of his duties are performed by the general practitioner. The code is written in dignified eighteenth-century English, and is full of delightful paragraphs. We may quote from Paragraph VII. of Cap. I., dealing with the assistance which a medical man may give a hospital patient in making his will. "It is one of the circumstances which softens the lot of the poor, that they are exempt from the sollicitudes attendant on the disposal of property. Yet there are exceptions to this observation . . . ." The late Lord Bowen must, we think, have been acquainted with Percival's dictum when on rising to his feet after dinner he began thus: "It must have been no small solatium to the prophet Daniel under the somewhat trying surroundings of the lions' den, to be able to reflect that when the dread banquet was at an end, he would at least be free from the sollicitudes attendant on the responsibilities consequent upon having to return thanks."

Annotations.

"Ne quid nimis."

RESPONSIBILITY OF THE CRIMINAL LUNATIC.

THE current law, practice, and procedure, relating to criminal trials in which the plea of insanity is raised as a defence has been subjected to more or less criticism for nearly a century, such criticism reaching a peak in 1843 and in 1923, following the acquittal on grounds of insanity respectively of McNaghten[1] and Ronald True. Each of these trials aroused public feeling, and each was followed by an official attempt to investigate the sanctions on which the law was based and interpreted. The famous McNaghten rules were the outcome of one inquiry, and the report issued this week of the committee, constituted in July, 1922, by the Lord Chancellor, may prove the thread on which a pronouncement of hardly less importance will ultimately crystallise. The committee consisted of Lord Justice Atkin (chairman), Sir Ernest Pollock, Sir Leslie Scott, Sir Herbert Stephen, Sir Richard Muir, Sir Archibald Bodkin, Sir Edward Troup, Sir Ernley Blackwell, and Sir Edward Marshall-Hall, and the reference was as follows: To consider what changes, if any, are desirable in the existing law, practice, and procedure relating to criminal trials in which the plea of insanity as a defence is raised, and whether any and, if so, what changes should be made in the existing law and practice in respect of cases falling within the provisions of Section 2, subsection (4) of the Criminal Lunatics Act, 1884. The difficulties of the committee in arriving at their report were not lessened by the divergence between the views presented for their consideration by the British Medical Association and by the Medico-Psychological Association. It is the proposals of the first-named association with which the committee is in substantial agreement, and these are in the main conservative, favouring the retention of the existing law with certain modifications. The report of the Medico-Psychological Association, which would substitute other questions for the jury than those now submitted, was set out in full in our issue of April 7th last. The rules proposed by this body would, it is contended, throw upon the prosecution the onus of establishing that the insanity said to exist was not calculated to influence the act complained of, and, in default of the discharge of such onus would compel the court to order the accused to be detained during His Majesty's pleasure. In the opinion of the committee the effect of this change of procedure must be to transfer many inmates of prisons to criminal lunatic asylums, and to bring within the portals of the latter many persons who are now, without any public disadvantage, placed under the care of relatives. We reserve detailed comment on the findings of the committee, while welcoming its report as voicing the legal aspect of an admittedly difficult problem. The distinction between sanity and insanity, between grades of mental incapacity, and its bearing on responsibility for antisocial acts, has become less easy to draw as our knowledge of mental processes widens. It is not without significance that medical opinion was divided, and it is possible that the coöption of one or two medical members on the committee would have been helpful. We are to this extent in agreement with a conservative attitude at the present time—that the law works slowly, and that in the near future our ideas on psychiatry in the light of the more recent advances in psychology are likely to undergo drastic revision. The report of the Medico-Psychological Association, while it may not prove acceptable as a basis for immediate change in legal procedure, may well point the direction in which this change is likely to occur.

---

[1] It is odd that the most diverse spellings of this name should occur in different, and sometimes in the same, legal or medical text-books. We have previously adopted the form M'Naughton, which is that given in "Reports of State Trials," New Series, 1892, vol. iv. (1839–1843). We now follow that of the official report.

BACTERIA DIGESTING CELLULOSE.

THE problem of the digestion of cellulose by man and animals is one of great interest, since it has shown that as much as 90 per cent. of ingested cellulose may disappear in the human intestine, whilst, on the other hand, it is well known that the digestive juices do not act upon cellulose. Consequently, attention has been directed to the influence of micro-organisms upon this capriciously resistant substance. Omelianski has especially studied the bacteria which attack cellulose, and has isolated two varieties, both anaerobic and both morphologically similar, but distinguished by the fact that one produces methane in abundance, whilst from the fermentation occasioned by the other hydrogen is liberated. Recently, at the suggestion of Weinberg, Mme. Y. Khouvine[1] has succeeded in isolating a similar organism from the human intestinal tract. This organism, which she designates the *B. cellulosæ dissolvens*, is an anaerobic, sporing bacillus which has extremely limited conditions of growth, and shows a slow but definite ability to digest cellulose with the production of carbon dioxide, hydrogen, alcohol, and various fatty acids. Curiously this organism, which can break down so complex a molecule as that of cellulose, appears quite unable to utilise the simple carbohydrates and sugars for its nutrition, or even to attack these when they are present along with cellulose. This specialisation with regard to the food requirements of the organism is of some interest in connexion with its rôle in the intestine, since the work of Mme. Khouvine would show that it liberates from cellulose substances having a certain food value without disintegrating other substances of this kind which may be present in the surrounding medium.

HYGIENE IN GIBRALTAR.

HYGIENE in Gibraltar is something of a special problem, for, while the total area of the territory is 1387 acres, that of the city is only 104 acres, and the population as estimated by the police at the end of 1922 consisted of 16,182 British subjects and a floating population of 1145 aliens. To these are added between morning and evening gunfire a daily visiting population of some 10,000 aliens and 1500 British subjects resident in La Linea. Major G. S. Parkinson's report for 1922 sets out the difficulties and how some of them have been met. There are three kinds of water-supply—namely, rain-water for drinking purposes, a brackish water for street flushing and sanitary purposes, and well-water for the shipping. Drinking-water is obtained from roof catchment areas by occupiers and stored in underground tanks. The city council have catchment areas and reservoirs in the Upper Rock, from which they supply the public and shipping after purification by 15 days' storage. At the beginning of June, 1922, the underground tanks of the houses became exhausted and supplies were obtained from Algeciras in tank boats. Samples of water from wells in La Linea were submitted but did not come up to the required standard. Many additional water vendors were licensed, a regulation being made for all water vendors to wear a brassard stamped with their registration number. The price of the drinking-water to shipping is 2*s*. per 100 gallons, to private houses 1*s*. 3*d*. per 100 gallons. Schemes for improving the catchment areas are under consideration, which will entail considerable outlay. There is a constant supply of brackish water laid on to every house for sanitary and general purposes. The water carriage system in force worked well during the year. Gibraltar has its housing problem also. A scheme for building 12 tenements was abandoned because the rentals would not have been economic. Much progress has, however, been made in getting existing houses into a better state of repair. Major Parkinson deals at some length with the high death-rate from pulmonary tuberculosis and its connexion with bad housing. He instances a case of eight persons living in one room, two being affected by pulmonary tuberculosis, one in an advanced stage. The campaign against street spitting often meets with derision from unenlightened quarters. Attention is being given to the schools. The flat roof of one school is used for open-air classes, for which the climate is well suited. A nursing sister from the Colonial Hospital visits the schools in turn and recommends for hospital treatment such children as seem to need medical attention. Unqualified midwives still flourish in the city, but steps are being taken to put an end to their employment. Of certified midwives there are at present seven in practice. The maternity ward at the Colonial Hospital does not as yet attract the class of woman for whom it was opened—viz., the poor woman living in bad surroundings, the usual reason given being that she cannot leave the other children. A beginning has been made with a child welfare centre, at which the attendances were one-third more than in the previous year and the opening of the new children's ward at the Colonial Hospital fills a long-felt want. The infant mortality-rate for the quinquennium 1918–22 was 113·2, as compared with 107·5 for the five years 1908–12. In spite of various relief works, the year 1922 was a hard one for many families on account of unemployment, and a supplementary grant of £700 was allotted by the Colonial Government to the Destitute Sick and Tuberculosis Scheme. In all 179 families received outdoor relief in the form of food tickets for meal and milk as against 158 families in 1921. The nurse appointed under this scheme paid 630 visits to sick people. The Gibraltar Home for Sick and Aged was full (54 inmates on Christmas Day) and its arrangements have been improved. An outbreak of rabies in the kennels on the North Front necessitated the destruction of all the hounds. The Muzzling Order was in force from March till October and, rabies being also reported at La Linea, restrictions were placed on the introduction of dogs. Inquiries elicited a reply from the Pasteur Institute that the preventive inoculation of dogs is as yet only in the experimental stages. The city council have enacted that all applicants for employment under their administration must be medically examined, and the procedure for the treatment of injured workmen at the Colonial Hospital has been greatly simplified.

MEMBRANOUS CONJUNCTIVITIS.

FROM the current *Bulletin* of the Ophthalmological Society of Egypt we learn that an epidemic of what was diagnosed as true diphtheritic conjunctivitis took place at Assiout last August and September among babies suffering from acute purulent ophthalmia. The infection was always mixed, and in no case could the diphtheria bacillus be demonstrated on smear preparations from the conjunctiva. Nevertheless, in 22 cases cultures proved that the disease was actually caused by the diphtheria bacillus. In a paper by Dr. A. F. MacCallan and Dr. Rasheed Bey the opinion is expressed that no reliance can be placed on the results of microscopical examination of smear preparations from the conjunctiva as regards the causative condition in suspected cases of diphtheria. It is essential to make cultures from the membrane if possible, or from the discharge. The growth on blood serum of typical colonies containing a bacillus which is morphologically identical with the diphtheria bacillus affords strong presumption that the case is actually one of diphtheria. It is, however, only by the isolation of the bacillus in pure culture and experimentation on the effect of injection into guinea-pigs that complete certainty can be established. This was done in four of the 22 cases. In only one of these cases was the conjunctival affection accompanied by faucial or nasal diphtheria; none of the cases was followed by paralysis of accommodation (it is not stated whether paralysis of the external eye muscles was noted). Sixty-three per cent. of these cases had ulceration of the cornea, and in half the cases one or both eyes were lost. As the clinical condition of the eyes may be exactly the same in membranous conjunctivitis whether it is due to the diphtheria bacillus or not, it is advisable to give one dose of the antitoxin without waiting for the bacteriological report, and in cases of doubt this should be repeated for some days, but as in real diphtheritic cases one of the effects is the rapid disappearance of the membrane, if this does not happen the probability is that the case is not diphtheritic. The important question arises when a case of membranous conjunctivitis comes to the surgeon whether it is advisable to isolate it. These authors, taking into consideration the uncertainty of clinical diagnosis, recommend that this should be done pending bacteriological proof. Another important prophylactic measure necessary in Egypt is to treat the patient in a fly-proof room or tent.

---

[1] Digestion de la cellulose par la flore intestinale de l'homme: *B. Cellulosæ dissolvens*, n.sp. Mme. Y. Khouvine, Annales de l'Institut Pasteur, vol. xxxvii., No. 8, August, 1923.

Comparing this Egyptian epidemic with the cases reported in England—the late Mr. W. H. H. Jessop,[1] in 1902, reported 13 cases of membranous conjunctivitis, of which eight may be considered to have been proved to be diphtheritic, three of them indisputably so by the injection of products of culture into a guinea-pig. As far as the diagnosis between diphtheritic and non-diphtheritic cases goes, the membrane, he says, can in no way settle the point, the slighter cases being exactly alike. In only one of these cases was the eye lost, and most of them made a complete recovery. In the same year[2] Mr. Sydney Stephenson reported 43 cases of conjunctival diphtheria seen among 3412 out-patients, so that the affection, in his experience, is not such a very rare one. In every case the Klebs-Löffler bacillus was demonstrated, associated with other micro-organisms in about half. Antitoxin was administered in 23 cases, and of the whole series all but one recovered.

IS PRIMARY NON-GONORRHŒAL URETHRITIS COMMON?

WHEN, in a case of acute urethritis evidently not due to chemical or mechanical factors, gonococci cannot be found in the discharge, it may be difficult to make a definite diagnosis. A recent paper by Dr. E. Björling,[3] of Malmö, raises the question with which this annotation is headed, and answers it emphatically in the negative. He argues that when such cases of primary, so-called "non-gonorrhœal urethritis" are scrutinised and the history of the case is carefully investigated, evidence can almost invariably be found pointing to a comparatively recent or old infection with gonorrhœa. He has collected all the 18 cases of primary "non-gonorrhœal urethritis" in the male that he has seen within the last few years, and he has come to the conclusion that in none could the diagnosis of gonorrhœa be eliminated. He maintains that, now and then, a man may suffer from acute gonorrhœa without knowing of its existence; he may not be conscious of it till an acute posterior urethritis sets in with its usual discomforts, and if he escapes this complication, the attack may pass off and temporary recovery may occur without his knowing that he has suffered from gonorrhœa. Some years ago Dr. Waelsch described a urethritis which he regarded as non-gonorrhœal, both because the bacteriological evidence was negative and no history of gonorrhœa was forthcoming. Dr. Björling notes that the cases recorded by Dr. Waelsch presented many features characteristic of his own cases. In both groups the urethritis was remarkably refractory to treatment. This refractoriness can, to a certain extent, be explained by the assumption that the source of infection may be an undiagnosed case of gonorrhœa with which the patient continues to be in contact. Dr. Björling's paper is a sobering corrective to the attitude, still adopted in some quarters, according to which, when gonococci disappear from the discharge, the disease is regarded as cured. There are, unfortunately, conflicting views on this point. According to some authorities the so-called post-gonorrhœal catarrh—i.e., urethritis persisting after an attack of gonorrhœa, and without demonstrable gonococci—is not infectious. Dr. Björling and others regard this standard of recovery as far too lax, and his carefully annotated case records show that gonorrhœa may run a curiously subterranean, latent or symptomless course, digging itself in unobtrusively, and troubling the patient only after a long interval. A further lesson of Dr. Björling's paper is that many an obscure case of urethritis can be traced to the gonococcus if the physician takes the trouble to examine the partner with whom the patient is cohabiting.

PARATHYROID TETANY.

WHEN the parathyroids are completely removed, the result in the experimental animal is rapid death with acute symptoms, which generally takes the form of tetanic convulsions. Some experimenters hold that the function of the parathyroid is to render inactive certain toxins formed elsewhere in the body, in particular the decomposition products (amines) resulting from bacterial action on proteins in the intestine. An American physiologist, Mr. R. Lester Dargstedt, has recently conducted further research on this subject, of which an account is given in the current issue of the *American Journal of Physiology*. His experiments were made on dogs and he found that if the parathyroids were completely removed the animals remained alive for at least a year provided their diet contained a large amount of lactose. In pregnant animals, however, the lactose diet is ineffective, as those animals died of tetany, perhaps because the poisonous substances were absorbed by the uterus. If dogs, with parathyroids removed, were fed for six weeks on milk-sugar diet and then fed on ordinary diet they remained healthy. Perhaps other organs—e.g., the liver—take up the function of the parathyroids and compensate for their absence. This suggestion is made because if in these animals the liver is injured by poisoning with phosphorus, tetany develops. Animals deprived of their parathyroids are particularly susceptible to the onset of tetany. The administration of much flesh food, constipation, muscular over-exertion on a warm day, or infections of various kinds may excite its onset. Such animals are also much more susceptible to the action of spasm-producing poisons.

THE ERADICATION OF TUBERCULOSIS IN CATTLE.

A WELL-REASONED article by Prof. B. Bang, of Copenhagen, in the last issue of the *Journal of Comparative Pathology and Therapeutics* tells of 24 herds in Denmark which were freed from tuberculosis at small cost and not a few farmers rescued from the verge of bankruptcy by the measures Bang advocates. The principle of his method is to separate diseased from healthy cows by means of the tuberculin test, to isolate each group, and then to add, on birth, all calves of tuberculous cows to the healthy herd and to get rid of their tuberculous mothers. To save time the intracutaneous application of tuberculin is coming into favour. The reason for this plan is that calves are almost invariably healthy when born. They are brought up on their mother's colostrum on the first day, and later either on raw milk from healthy cows or on milk heated sufficiently to destroy tubercle bacilli. One of the farms successfully cleared up by this method was that which sent a supply of milk for infants—i.e., certified milk—into Copenhagen. Applications twice yearly of the tuberculin test to the healthy section have to be kept up to prevent introduction of the disease and to get rid of reactors. The fairly numerous cases statistically and narratively given by

---

[1] Trans. Ophthalmological Society, 1902.

[2] Ibid.

[3] Acta Dermato-Venereologica, 1923, vol. iv., Fasc. 2.

Bang show that by this method, used with care and perseverance, even badly infected herds may be cleared up in a few years and a healthy stock produced. It differs from "the accredited herd plan" prevalent in America in that there all reacting animals are slaughtered, some compensation being given by the State. Bang's method is more economical and he shows that it can produce very excellent results; 1676 herds, comprising 47,627 cattle have been tested. This isolation method has given very great satisfaction also in Sweden, Finland, and Hungary. The query remains as to what becomes of the tuberculous cattle that are sold? Bang's article does not tell us. But this is a most important point. If the buyer is not under an obligation to slaughter forthwith, the transaction, from the prophylactic point of view, is somewhat like borrowing from Peter to pay Paul.

INTRAVENOUS INJECTION OF CAMPHOR.

CAMPHOR as a circulatory stimulant is in much greater esteem on the continent than in this country. Subcutaneous injections have long been used, especially for children, but it is only recently that it has been shown that camphor oil can with impunity be injected directly into the circulation, and that the reaction is immediate. The stimulating effect on the circulation of camphor oil given intravenously has recently been emphasised by Dr. Erich Schilling,[1] of Küchwald, in Chemnitz. Dr. Schilling has used camphor in this way in all cases of marked collapse. In particular has he found it useful in cases of poisoning, his material comprising some 45 cases. It is especially indicated in coma, following gas-poisoning, as illustrated by the following case: A girl was brought in who had lain for three to four hours in an atmosphere of gas. She was completely unconscious, and reacted only slightly to stimulation of the skin. Three minutes after injection of I c.cm. camphor oil she opened her eyes, sat up, asked where she was, and answered clearly all questions put to her. In only four cases, two of morphia and two of gas-poisoning, was no effect obtained with camphor. Even if it is granted that the majority of cases of gas-poisoning recover without any treatment, yet from Dr. Schilling's experience it is clear that consciousness returns much sooner after the use of camphor and thereby the danger of inspiration pneumonia is considerably decreased. Although consciousness is usually regained after the first injection, in severe cases the treatment may have to be repeated two or three times at intervals of six hours.

INCOME-TAX EXEMPTIONS IN THE DOMINIONS.

A RECENT publication [2] issued by Somerset House gives a wealth of information regarding Income-tax rules in different parts of the Empire. So far as has been observed, the only places in which there are special rules which have a direct interest for the medical profession are the Tanganyika Territory and the State of Victoria. The African colony has a primitive ring in its name, but its tax code is from the medical standpoint a model to the world. Perhaps the very existence of an Income-tax proves distinct progress in civilisation, and a code that absolutely exempts from taxation all profits from the practice of the profession of licensed medical practitioner or dentist, and from the sale of drugs and surgical, medical, or dental appliances to the practitioner's patients has obvious merits to our eyes. These are the only professions so selected for legislative grace, not even the church sharing in the distinction, which is surprising, for there are one or two Dominions in which clergymen are exempt. It will be understood that this Tanganyika concession is unconditional (except for the "licensed") and unlimited as regards amount of income. In Victoria, Australia, among the deductions allowed in bringing out the taxable income, in cases where the total income does not exceed £800, are payments in respect of the illness (including surgical treatment) of the taxpayer himself, his wife, or any of his children under the age of 21, to (1) any legally qualified medical practitioner or any public or private hospital, (2) any nurse, (3) any chemist. Dental treatment is not mentioned. There is a limit of £2 under each of these three heads, but that does not mean that not more than £2 will be passed, but on the contrary that, if the total expenditure on any one of those heads (we understand for one illness) *does not exceed* £2, it must be ignored. This is a novelty in Income-tax legislation. The next allowance in Victoria embodies another new idea—namely, £20 for the funeral of the taxpayer's wife or any minor child, but not of the taxpayer himself.

AGAR-AGAR.

Agar-agar is an interesting substance, although little appears regarding its properties in current manuals of materia medica. The U.S. Pharmacopœia, in which it is officinal, describes it as the dried mucilaginous substance extracted from *Gracilaria* (*Spærococcus*) *lichenoides* Greville and other marine algæ growing along the eastern coast of Asia, particularly several species of *Gelidium*, or *Gloiopeltis* (Class Rhodophyceæ). For many years these algæ have been used in the Far East under the various names of Ceylon moss, Japanese isinglass, and Javan alga for the preparation of foodstuffs, drugs, and adhesives. A decoction of these plants forms a jelly-like fluid, known as agar-agar, employed largely in some parts of Europe as a substitute for gelatin in the arts. The use of agar-agar in the preparation of bacterial culture-media is sufficiently familiar. It is noteworthy that a solution containing 0·5 per cent. of agar possesses the same adhesive strength as one containing 3 to 4 per cent. of the ordinary animal or fish glue. Commercially it is prepared by heating algæ in water in an autoclave at 120° C. for some hours; the viscous fluid is filtered while still hot, and the filtrate, after solidifying, is cut into strips. Gelatinisation, which does not take place unless the agar content is above 0·1 per cent., is due to gelose, a carbohydrate first described by Payen, who showed that a hot solution was coloured yellow by iodine, the colour changing to purple on cooling, and to blue on the addition of a few drops of H_2O_2. Gelose also reduces ammoniacal silver nitrate solutions on boiling. Agar dissolves completely in concentrated HCl or H_2SO_4; it is insoluble in glacial, but readily soluble in dilute acetic acid. Through the action of alkalies its solutions cease to gelatinise, but become much more adhesive; addition of borax gives the maximum amount of tenacity. Agar solutions do not reduce alkaline copper solutions except after prolonged boiling, and with most samples it is necessary to induce hydrolysis with H_2SO_4 before Fehling's solution can be reduced. No furfural reaction is given on heating with concentrated H_2SO_4. Agar is distinguished from gelatin by the fact that a precipitate results on the addition of sodium meta-phosphate to a boiling solution, while with gelatin there is no precipitate. Tannic acid precipitates agar from its solutions, but the precipitate redissolves on heating. Analysis of agar-agar has revealed the following constituents: 1. Carbohydrates: gelose. 2. A colloidal glue-like substance. 3. Starch. 4. A series of carbohydrate bodies such as pararabin, metarabin, xylose, and cellulose, all of which yield sugar on hydrolysis with dilute acids. 5. A slime soluble in water and of unknown constitution. Gelose is undoubtedly the most important of the constituents. This body was at one time thought to be identical with pararabin, but this can be disproved by the fact that on hydrolysis gelose yields galactose whilst pararabin does not. The provisional formula $C_{24}H_{38}O_{19}$ (i.e., $4C_6H_{10}O_5—H_2O$) has been allotted to it. Pharmacologically little is known about agar-agar. It is used in the East to a limited extent as a food, although according to Saiki the human digestive tract is able to utilise but a very small percentage of the food value. Administered by the mouth it is stated to reduce the coagulation-time of the blood. Gelose is said to draw water into the gut and hence to act as a saline purge. Certainly by absorbing water from the stomach and increasing the bulk of the intestinal contents it acts as a laxative, a dose of 8–15 g. being employed for the purpose. A powerful anaphylatoxin results from digesting agar with guinea-pig serum. Finally, since marine algæ are continually discharging agar into the sea the question has been raised why it does not accumulate in the sea-water. The answer is apparently that sea-water contains bacteria which are capable of digesting it. Much information about agar-agar is contained in Abderhalden's useful "Biochemical Lexikon."

SCIENCE IN THE KITCHEN.

THE French have always placed the good cook among the artists, and now, it would appear, they would make him a scientist too. The Under-Secretary of State for Technical Education in France has decided to patronise the Scientific Society of Alimentary Hygiene, and thus, supported by the Government, classes have been organised for teaching the "higher culinary arts." To boil a potato or to grill a chop hardly calls for a specialised medico-chemical training, and yet doubtless when the chef aims to strike some harmonious gastronomic chord, chemistry should decide what is wholesome, while medicine may indicate the particular requirements of the invalid. The State lecturer, it may be presumed, will deal with the hygiene of food, with the technique of cooking, and with the preparation of dishes to meet invalid needs. He will also be informing on the purchase of foodstuffs, but if here he can teach the French housewife anything he will be a wondrously well equipped man. The staff of instructors includes Dr. Hemmerdinger, an experienced lecturer on domestic economy; Dr. Henri Labbé, professor in the Faculty of Medicine at the University of Paris; and Mr. Martel, member of the Academy of Medicine and director of veterinary services under the Prefecture of Police; and we see here indicated three main directions of instruction outside the ordinary cooking lesson, the hygienic claims and the need for thrift being considered and some knowledge of substituted foodstuffs being imparted. The classes will meet in the forenoon every Thursday, at 2, rue Clotilde, Panthéon (5^e), and pupils are to be enrolled at the offices of the Scientific Society of Alimentary Hygiene, 16, rue de l'Estufade, Panthéon (5^e).

THE Thomas Vicary Lecture will be delivered in the Royal College of Surgeons of England by Sir Arthur Keith, F.R.S., on Dec. 7th, at 5 P.M., the subject being the Life and Times of William Clift, First Conservator.

THE collection of drawings of war injuries of the fundus oculi, presented by Dr. W. Wallace, late Temp. Captain, R.A.M.C., to the Army Medical War Museum, is now available for study at the museum of the Royal College of Surgeons of England.

DONATIONS AND BEQUESTS.—During the past month the Royal Manchester Children's Hospital has received subscriptions and donations amounting to £852, including £200 from deceased benefactors, and £200 from the Salford Corporation.—By the will of the late Mr. James Mackersie, of Randolph-gardens, Broomhill, Glasgow, the testator left, among other bequests, £2000 to the Royal Infirmary, Glasgow; £2000 to the Western Infirmary, Glasgow; £2000 to the Victoria Infirmary, Glasgow; £500 to the Glasgow Benevolent Society for the relief of the destitute sick and those in extreme poverty; £250 to the Princess Louise Scottish Hospital for Limbless Sailors and Soldiers; £250 to St. Dunstan's Hostel for Blinded Soldiers, Regent's Park, N.W.; and £250 to the Royal Hospital for Sick Children.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XLVII.—TREATMENT OF COLLES'S FRACTURE.

THE classical fracture involving the lower extremity of the radius described long ago by Colles, of Dublin, is a relatively uncommon type of injury. But the term Colles's fracture to-day is held to include most complete fractures of the radius located within an inch of the lower articular surface of this bone. These fractures are seen at all periods of life, but are frequently sustained by elderly females. Before the age of 20, a separation of the lower epiphysis of the radius is the equivalent of the fracture of later life. In most instances a Colles's fracture is produced by a fall on the outstretched hand, the point of impact being the palmar aspect of the fully extended wrist. A compressing force is transmitted upwards and the radius breaks across at its weakest spot. Less commonly the back-fire of a motor starting handle may wrench off the lower end of the radius, but the most frequent radial back-fire lesion is a crack running through the site of the old epiphyseal line.[1]

The line of a Colles's fracture is roughly transverse. Impaction almost always occurs, but gross comminution is rare. The displacement of the lower fragment is largely determined by the direction of the transmission of the violence, and occurs in three planes: (1) The lower fragment is forced upwards and backwards en masse, and becomes jammed into the cancellous tissue of the shaft. (2) This fragment is deviated radialwards, and with it the hand. (3) A rotation occurs on a transverse axis, a hinge-like movement, so that the articular surface now looks downwards and backwards instead of downwards and forwards. The styloid process of the ulna is subjected to great strain, and finally fractures at its tip. Sometimes the attachment of the triangular fibro-cartilage to the base of the ulnar styloid is torn through, allowing an undue amount of separation between the lower ends of the two forearm bones. Often no appreciable deformation is recognisable.

Clinical Features.

Within a few hours considerable swelling develops in the wrist, dorsum of the hand, and lower third of the forearm, and may mask any slight bony deformation; if crepitus cannot be demonstrated, a fracture may not easily be recognised. A displacement, such as the "dinner-fork" deformity of the older text-books, is rare; usually the signs suggest little more than a severe contusion or strain. Comparison of the injured limb with its fellow of the opposite side allows minor degrees of displacement to be appreciated. These include (1) a radial deviation of the hand; (2) a palpable swelling involving the region of the lower fourth of the radius with a loss of the normal anterior concavity of this bone. This change in shape depends on (*a*) the projection of the lower end of the shaft on the flexor aspect of the wrist, and (*b*) the projection of the backwardly displaced lower fragment on its extensor aspect. The overlying tendons add to the localised bulge in both areas. Crepitus may be elicited in unusual cases, but is generally absent. (3) The radial styloid process may be displaced slightly upwards so as to be on the same level, or even higher than its fellow bone. The absence of a relative alteration in the position of these points does not contra-indicate the diagnosis of fracture. (4) The rounded lower end of the ulna is abnormally prominent. A radiogram, which should be taken without delay, will confirm the diagnosis and disclose the extent of the fracture and the plane of displacement. After 24 hours the swelling of the soft parts may rapidly increase, particularly in elderly people. The fingers become swollen and of a sausage shape, and the whole region is exquisitely painful and tender.

---

[1] Bizarro: Surg., Gyn., and Obstet., May, 1922.

The skin often becomes glossy, and the fingers and wrist-joint lose mobility. In younger individuals this picture is characteristic of the neglected case.

The whole of the upper limb should be inspected and palpated, as a contusion of the shoulder-joint may be produced by the same force that caused the fracture, and may be overlooked until the development of stiffness and pain many weeks later indicate the existence of a traumatic periarthritis or actual adhesions within the joint capsule. A fracture of the *scaphoid* may be produced by the same type of violence as a Colles's fracture. The two lesions may occasionally coexist. Signs which in themselves suggest a scaphoid lesion are (*a*) swelling and tenderness located to the scaphoid area (the anatomical "snuff-box"); and (*b*) pain elicited by abducting the thumb or extending the wrist.

Recent Impacted Cases with Obvious Deformity.

In every Colles's fracture, with displacement seen within the first few hours of the injury, complete and perfect reduction should be aimed at. In non-impacted cases, where there is gross displacement, reposition may sometimes be obtained with ease. But where impaction with deformity is present, considerable force may be needed to correct the displacement of the lower fragment. Under such circumstances it is wise to have the patient fully anæsthetised. Disimpaction without an anæsthetic is a manœuvre for the expert fracture surgeon only.

(*a*) *Reduction.*—The traditional method of reduction—often called the "hand-shaking" method—where an indirect force is utilised, is open to many objections on mechanical grounds. The employment of a direct corrective force applied to the displaced fragments by means of the thenar eminences of the hands of the surgeon is a far more logical and effective procedure. This method, introduced long ago by H. O. Thomas, of Liverpool, has been taught repeatedly by Sir Robert Jones, and is now practised widely. With the lower fourth of the radius controlled directly by the surgeon in this way, disimpaction may be achieved and the lower fragment brought forwards, the rotation and radial deviation being corrected at the same time. The outstanding sign of a perfect reposition is the restoration of the anterior concavity of the radius in the fractured area. Also, the normal relation of the styloid processes should be capable of demonstration. The accuracy of the correction is best appreciated when the wrist is fully flexed.

(*b*) *Retentive Splinting.*—Where a definite impaction with displacement has been reduced there is always a tendency to redisplacement, and accurate splinting is thus necessary to prevent a recurrence of the deformity. Many "special" splints have been devised for the treatment of Colles's fracture, but most of them are suitable for cases where no displacement exists, and where splinting is really unnecessary. The most efficient and comfortable control of a reduced Colles's fracture is attained by the use of two ordinary gutter-shaped fracture splints made of light sheet iron or aluminium, the latter possessing the advantage of being permeable to the Rontgen rays. Two corrective gauze pads are first placed in position, one on the extensor aspect exerting a forward thrust on the lower fragment, the other at a higher level on the flexor aspect of the forearm to control the upper fragment. The application of the splints holds the pads in place, and the fracture is now secure. The posterior splint extends from the outer condyle of the humerus to just behind the metacarpo-phalangeal joints; the anterior splint from the elbow to the base of the thenar eminence. A turn of adhesive strapping above and below ensures fixation, but the addition of a bandage is a wise precaution. Following the practice of the Liverpool School, the splints should be twisted spirally but in opposite directions before their application. By this means the forearm is supported in four planes instead of two, and sagging of the ulna prevented. The splinted limb is now suspended in a sling with the elbow at right angles.

(*c*) *After-treatment.*—The fingers being left free, the patient carries out active movements of all digits from the first. If œdema is marked, very light massage may be instituted, but must be limited to the area exposed. It is usually unnecessary to take off and readjust the splints before the fourth day, and often they may be left until the end of the first week. From this time onwards one splint may be removed daily and the lightest massage applied to a much greater area provided (*a*) the fracture shows no tendency to redisplacement, and (*b*) the services of a masseuse specially trained in the treatment of recent injuries in a large fracture clinic are available. During such treatment the position of the fragments must be absolutely controlled, and at the conclusion of each sitting the pads and splints replaced accurately. By the end of the second week gentle *active* movements of the wrist may be attempted, the fracture meanwhile being controlled between the thenar eminences of the masseuse. In addition, a short range of pronation and supination should be essayed. Any increase in pain, tenderness, or local swelling after such movements is an indication that the masseuse is going ahead too rapidly. The splints are retained on the average until the end of the third week, when the fracture should begin to feel firm. At this stage it is a wise precaution to keep on one splint or two smaller light splints merely as a guarding apparatus, for it must be remembered that the callus is easily strained. The range of movement at the wrist and radio-ulnar joints should be increased by gradual degrees. Active movements, which are now carried out with little or no discomfort, should be supplemented by gentle assisted movements. It may be emphasised here that the traditional *passive* movements have no place in the treatment appropriate to this stage. By the sixth week there should be an absence of any œdema of the hand or forearm, the fingers should be mobile, and the wrist capable of taking a fair degree of strain without reaction. The sole remaining disability will probably be a slight limitation of supination, usually remedied by passive stretching by the masseuse. Finally in the gymnasium the wrist is tested by special exercises. The cosmetic result obtained varies considerably, but in many cases where the symmetry of the wrist is not restored perfect function may be seen.

Recent Impacted Cases without Obvious Deformity.

In these cases a radiogram may often reveal the existence of slight rotation of the lower fragment, and it is not uncommon to notice at a later stage that the radius is definitely shortened and the lower end of the ulna unduly prominent. In the presence of such anatomical defects, full functional capacity may be restored by the *immediate* institution of the physio-therapeutic measures already detailed. Although splinting is unnecessary to maintain correction, it adds to the comfort of the patient if light aluminium splints are worn for the first week. On the advisability of correcting barely appreciable displacement opinions are divided, but it is generally agreed that in elderly people no attempt should be made to disimpact, nor in cases seen a week or more after the accident.

Treatment of Neglected Cases.

Where there is gross deformity or actual malunion accompanied by disabling sequelæ, operative correction is indicated, but not necessarily open exploration. Up to two weeks from the time of the injury it may be corrected by manipulation alone, or by means of the Thomas wrench. After the third week an open operation will be advisable, and should consist in merely cutting through the line of union and replacing the lower fragment without employing internal fixation. In elderly patients it is rarely wise to undertake operative measures, and an attempt should be made to restore function by physio-therapeutic treatment, the deformity being ignored.

HARRY PLATT, M.S., M.D., F.R.C.S.,
Senior Hon. Surgeon, Ancoats Hospital, Manchester.

Special Articles.

THE SHORTAGE OF NURSES:

SOME PROPOSALS FROM AMERICA.

THE shortage of suitable candidates for the nursing profession is not confined to this country. It is keenly felt in the United States, and a study of an exhaustive investigation of the reasons for this shortage in America shows that, though the conditions of training and subsequent responsibilities of nurses are not identical in the two countries, the problems to be faced are closely allied.

The Rockefeller Inquiry.

We set forth below the results of an inquiry by a committee originally appointed by the Rockefeller Foundation in January, 1919, to study the proper training of public health nurses.

There are at present two distinct types of public health nursing practice in the United States—that in which the nurse confines herself to the teaching of hygiene, and that in which such didactic work is combined with the actual care of the sick. A third type of visiting nursing, in which bedside care is given with no official educational service, as in our own district nurse systems, may be observed but is less common. The advantages of the second type, of combined instruction and care, are well set out in the report and should receive the attention of the district nursing associations and of local authorities in this country. The nurse who approaches a family where sickness exists and renders direct technical service in mitigating the burden of that sickness has an overwhelming advantage, then and thereafter, in teaching the lessons of hygiene. It is noted in the report of the committee that the relative lack of nursing personnel in Europe has there led to the attempt to train health visitors of the purely instructive type for dealing with special individual problems, such as tuberculosis or child welfare, by training courses much shorter than those required for the preparation of the nurse, but it is maintained that, at any rate for conditions as they exist in the United States, the teacher of hygiene in the home should be equipped with no less rigorous training than that accorded to the bedside nurse, further supplemented by special studies along the lines of public health and social service. Since this view is generally accepted in America, it soon became clear to all concerned that the entire problem of nursing and of nursing education, relating to the care of the sick as well as to the prevention of disease, formed one essential whole, and in February, 1920, the Foundation requested the committee to broaden the scope of their inquiry to include "a study of general nursing education, with a view to developing a programme for further study and for recommendation of further procedure."

The outcome of this inquiry has now been issued in book form.[1] It is the provision of sufficient competent nurses for the sick and the need of attracting good probationers to the nursing school that are problems of even more urgent importance in this country than the provision of public health nurses, and it is to the section of the report dealing with these that we propose to direct attention. There, as here, there is much discussion as to the quantitative and qualitative adequacy of the nursing service. As to the first point, according to the committee the reason why many persons who need nursing care in hospitals and in the homes of the poor fail to receive it is to be sought in economic factors rather than in a shortage of nurses. In regard to the quality of the nursing service available at the present day more radical differences of opinion are to be found. Private physicians frequently express the view that for ordinary nursing even the graduate of the existing training school is "over-trained," that the service which she renders is too costly, and that a woman with a very brief training in bedside routine would be as satisfactory, or perhaps more satisfactory, than the average registered nurse. As a result of this feeling there have been persistent and vigorous efforts in certain quarters to break down the standards of nursing education which have been laboriously built up during the past 20 years.

Two Grades of Nurses.

In so far as these efforts would remove the safeguards which guarantee to the patient suffering from acute disease, and to the physician caring for such a patient, the quality of service necessary for safety, it is felt that they constitute a real danger to the cause of public health. But having made this point, the committee proceed to give careful consideration to the question whether there is not scope for two grades of nurses, and conclude that for the care of mild and chronic illness and convalescence it may well be that a different type of capacity and training may be necessary. It seems clear to the committee, however, that, if two types of nursing service are desirable, the distinction should be drawn, not on economic grounds, but according to the type of illness involved. Careful estimates from 118 graduate nurses indicated that during a period of three months one-quarter of their time was spent on cases which could have been cared for by an attendant of the partially trained type. A somewhat similar estimate was obtained from 48 practising physicians, 21 believing that trained nurses were unnecessarily employed for less than a quarter of their cases, 17 placing the figure between one-half and three-quarters, and 10 at over three-quarters.

A subsidiary nursing service would be no new development. The "practical nurse," alias the "trained attendant," is an existing fact: and in the opinion of a large group of the medical profession who utilise her services she fills a real place in the complex problem of caring for the sick. On the other hand, the danger in the existence of a loosely-defined and unregulated group of partially trained workers, in the same field as a more highly educated type, constitutes a real and serious complication. The nursing profession has discharged a fundamental duty to the public in stimulating the development of registration laws, which define and delimit the practice of that profession, and protect the community against fraud and exploitation by those who assume responsibilities to which their qualifications do not entitle them. In addition to the registration of the trained nurse it is considered essential that the lower grade of nursing service should also be defined and registered, and the States of New York, Missouri, California, Michigan, and Maryland have taken definite steps in enacting legislation towards this end.

The Name for the Subsidiary Group.

The name to be selected for the subsidiary group is a difficult problem. As is so often the case, the root of disagreement lies largely in nomenclature. The title "attendant" is distasteful to those who bear it and tends to discourage the enlistment of those who may desire to enter this field. On the other hand, the term "practical nurse" assumes a most unfortunate antithesis between education and practice, and the splendid professional and public service rendered by "the nurse" in war and in peace, entitles her to the protection of her existing professional status. The term "nursing aide" or "nursing attendant" is suggested as that which best meets the need for clear differentiation, while providing the subsidiary worker with a suitable name. With two distinct grades of service available, the individual physician would be responsible for the choice of a trained nurse or a nursing attendant in a given instance. The subsidiary type of worker would serve under practising physicians in the care of mild and chronic illness and convalescence, and possibly assist under the direction of the trained nurse in certain phases of hospital and visiting nursing.

---

[1] Nursing and Nursing Education in the United States (Report of the Committee for the Study of Nursing Education). New York: The Macmillan Company. 1923. 15s.

The Hospital Training School.

The development of the hospital training school for nurses constitutes a unique chapter in the history of education. In almost all fields of professional life education has begun on a basis of apprentice training. The first law schools and the first medical schools were the outgrowth of the lawyer's and the physician's office. In nearly all other fields than that of nursing, education has outgrown the apprentice stage and leadership has passed into the hands of independent institutions, organised and endowed for a specifically educational purpose. The training of nurses, on the other hand, is still in the main directed by organisations created and maintained for the care of disease rather than for professional education. The progress which has been accomplished under such anomalous conditions is such as to reflect high credit upon both hospital administrators and the leaders of the nursing profession. Yet the conflict of interests between a policy of hospital administration, which properly aims to care for the sick at a minimum cost, and a policy of nursing education which with equal propriety aims to concentrate a maximum of effective training into a minimum time, is a real and vital one. The fact that the nursing profession fails to attract students in the number, and of the quality desired, strongly suggests that there is some shortcoming in the established avenues of approach thereto. The hospitals themselves, depending as they do so largely upon student nurses for their routine operation, have found themselves seriously handicapped by the small number of well-educated applicants. Inspection of 23 training schools representative of the best current practice in nursing education revealed some interesting points. For example, in some cases theoretic instruction was at fault; in others, ward duties appeared to be largely dictated by the need for hospital service rather than by the educational requirements of the students. This was evidenced by the astonishing irregularity of the time spent on different services by individual students and by the marked deviation between the duties actually performed and those scheduled in the official programme of the course.

The supervision of work in the wards was in certain instances notably inadequate. In only a few brilliantly exceptional cases was the ward work purposefully correlated with theoretical instruction. The lack of an intelligently planned progressive training was obvious in a large number of the hospitals studied, first year students often being found in positions of responsibility for which they were wholly unprepared, while seniors in another ward were repeating an educationally idle and profitless routine. Most striking of all was the factor of time wasted in procedures essential to the conduct of the hospital but of no educational value to the student concerned. Hours and days spent in performing the work of a ward maid, in putting away linen, in sterilising apparatus, in mending rubber gloves, in running errands, long after any important technique involved had become second nature, accounted in one typical hospital operating under the eight-hour system, where this problem was specially studied, for a clear wastage of between one-fourth and one-fifth of the student's working day.

The total amount of time assigned to ward service under the conditions which obtain in many hospitals is, in itself, a fairly complete obstacle to educational achievement. The selected group of hospitals, in this respect above the general average, showed a median day of between 8 and 8·5 hours on ward duty alone, exclusive of all classroom instruction. Irregular, excessive, and unproductive night duty was the rule rather than the exception. Crowded and unattractive living conditions tend, in certain hospitals, to impair the morale of the student body, and an atmosphere of autocratic discipline frequently prevents the development of a psychological atmosphere favourable to effective coöperative effort. It is emphasised that such shortcomings as have been pointed out are not fairly chargeable to deliberate neglect on the hospital authorities or nursing superintendents. In so far as they exist, they are due to the inherent difficulty of adjusting the conflicting claims of hospital management and nursing education, under a system in which nursing education is provided with no independent financial endowments for its specific ends.

Suggested Improvements.

The difficulties, however, are not insuperable. Each of them has been overcome in some schools and most of them in certain of the best schools. But that does not affect the view of the committee that one of the chief reasons for the lack of sufficient recruits of a high type lies in the fact that the average hospital training school does not offer a sufficiently attractive avenue of entrance to the nursing profession. Their recommendations for the improvement of the hospital training school include a raised standard of educational attainments for student nurses; a preliminary term of four months' training in the basic sciences and in elementary nursing procedures with appropriate ward practice but without regular ward service; and a period of 24 months (including two months for vacation) devoted to a carefully graded and progressive course in the theory and practice of nursing, with lectures and ward practice so correlated as to facilitate intelligent case study, and with the elimination of routine duties of no educational value. The working day for the student nurse, including ward work and classroom periods, should not exceed eight hours. The working week should not exceed 48 hours and preferably 44 hours. By such an organisation of the course of study, and particularly by the elimination of unrewarding routine service, it is held that the period of training might be safely shortened from the present standard of three years to 28 months. Such a saving would mean an increase of over 20 per cent. in the potential output of the training school through the saving of time alone. The shortening of the course would, in itself, prove an attraction to the prospective student, but the main consideration to be kept in view is that the shorter course projected would not imply a lowering but a raising of educational standards. It is the experience in every other field of education that the way to attract students is to raise standards, not to lower them. The fundamental essentials to the success of a training school planned on these lines are that it must be directed by a board organised for the primary purposes of education. The interests of hospital management and of educational policy must necessarily at times conflict, and unless the educational viewpoint is completely represented the training school will infallibly suffer in the end. In the second place it is fundamental to the success of nursing education that adequate funds should be available for the educational expenses of the school itself, and for the replacement of student nurses by graduate nurses and hospital helps in the execution of routine duties of a non-educational character. A satisfactory relationship between school and hospital demands careful cost-accounting and a clear analysis of the money value of services rendered by the school to the pupil and the hospital, and by the hospital to the pupil and the school.

The course of 28 months discussed above would furnish the complete education for a student desiring to practise as a bedside nurse in private duty or in hospitals and other institutions, and its completion should entitle her to a diploma in nursing and to State registration. For the nurse who desires to specialise along either of the more advanced lines of public health nursing, or hospital supervision and nursing education, a further period of post-graduate training is desirable.

Educational Provision for the Subsidiary Type of Nursing Service.

In the view of the committee there is a real place for a subsidiary type of nursing service, to be used in the institution and in the home for the routine care of patients suffering from disease of a mild or chronic type or in convalescence. It is pointed out that, whether approved of or not, this subsidiary nursing service is an existing fact, and that women whose only training is, say, a course in home nursing of a few weeks' duration, such as those conducted under the auspices of the American Red Cross, are actually engaged in nursing chronic cases throughout the country. Since the existence of the subsidiary nursing group is a concrete fact, and in view of the valuable results to be derived from the service of this group in a definitely restricted field, it is considered that specific provision should be made for the training of workers of this type.

The special hospital not served by affiliation with a school of nursing, and the small general hospital whose facilities are inadequate for the maintenance of a nursing school of standard grade might be considered as training grounds. The requirement for entrance should be a grammar-school course or its equivalent and the period of training approximately eight or nine months. It is essential in providing for this type of education that hospital patients should be protected from malpractice and students from exploitation by an adequate graduate nursing service for the care of acute illness and for supervision of the students. Again, therefore, reasonable financial support must be assured before this, or any other, educational enterprise can be honestly undertaken. It is further believed that a useful development in the training of nursing aides can be expected only when the standards of the schools for such aides and their activities after graduation are controlled by a properly safeguarded system of State legislation, such as now exists in Missouri. The Missouri Act is unusually effective in providing that "no person shall practise as a nurse for hire or engage in the care of the sick as an attendant for hire unless licensed by the Board."

The Financial Problem.

It is held that the educational plan outlined above is sufficient for the solution of the problems involved in securing an adequate nursing service of all essential types. The school for nursing aides would provide the subsidiary worker needed for the care of the mild and chronic and convalescent case. The hospital training school, with adequate funds and an independent educational organisation, would attract more candidates and better candidates and would prepare them adequately for the nursing of acute disease. The university school of nursing would prepare the leaders in public health nursing, in hospital supervision, and nursing education and would inspire and standardise the entire movement. It is clear that the attainment of these ends requires financial support. It is time, in the view of the committee, that the hospital should be relieved from the dilemma of exploiting student nurses on the one hand, or of diverting funds given for the care of the sick on the other, by the provision of endowment specifically devoted to the purposes of education.

NATIONAL MILK CONFERENCE.

Discussion on Pasteurisation.

About a year ago a conference on the milk problem was held at the Guildhall, London, convened by the National Clean Milk Society, and supported by a large number of societies interested in the public health, in agriculture, and in the dairying trade. On Nov. 21st, 1923, a second conference was held at the Guildhall under the same auspices and attended by many representatives of local sanitary authorities and the trades concerned, including representatives from the overseas dominions and foreign countries. The object of this second conference, as Mr. Wilfred Buckley, who presided at the morning session in the unavoidable absence of Lord Astor, explained, was to throw light on all matters connected with pasteurisation.

Trade Aspects.

Six papers were read and discussed, and of these three were concerned mainly with the trade side of the question. Dr. Richard Seligman dealt with the history of methods and apparatus, and explained the difficulty of ensuring that every particle of milk passed through an apparatus had been kept at the desired temperature for the desired period of time. He expressed the opinion that this result was as yet satisfactorily obtained by only one type of "positive holder" machine, but that the last word had not been said. He appealed to scientific men to help in perfecting methods, seeing that pasteurisation is, at the moment, absolutely necessary for the liquid milk trade. Mr. J. H. Maggs (United Dairies, Ltd.) considered the financial and commercial aspects of the question, and Mr. A. T. R. Mattick, B.Sc. (Reading Institute), dealt with the alterations of the cream line and cream layer caused by the various temperatures used for pasteurising. This is also a trade question. As long as the fat is in the milk, it does not matter from a public health or nutritional point of view how much of it comes to the top. To many people one of the attractions of homogenised sterilised milk in bottles is that the cream will not separate. However, the public naturally judge the richness of the milk from the thickness of the cream layer, and it was satisfactory to learn from Mr. Mattick that if the milk is held for 30 minutes at a temperature not exceeding 145° F., there is not likely to be much alteration in this layer. The other three papers dealt with the chemical, bacteriological, and so-called biochemical changes.

Chemical Changes in Pasteurised Milk.

Prof. G. B. Schryver (Imperial College of Science and Technology) introduced the subject of chemical changes. His paper did not suggest that any appreciable change was likely to occur as the result of a temperature of 145° to 150° F. for 30 minutes. He referred to the question of the alteration of the calcium and phosphate content of milk by heat and the possible precipitation of some of the calcium phosphate. He also mentioned the work of Daniels and Loughlin at Iowa University in 1920 on this subject, but, as these observers used boiling temperatures, their results had no bearing on the present instance. Mr. G. W. Monier Williams, Ph.D., following Prof. Schryver, said that as far as we knew chemical changes up to 145° F. were very slight. Lactalbumin was not coagulated, the action of rennet on milk was unaffected, and the calcium phosphate was not separated from the casein. Pasteurisation diminished the acidity and raised the freezing-point, but these results might be due to the driving off of the carbonic acid contained in fresh milk. Capt. Goulding (Reading Institute) thought we could not speak with certainty as to the meaning of the apparently small changes which took place at 145° F.

Bacteriological Changes.

Prof. J. M. Beattie (Liverpool) read a paper on the bacteriology of pasteurised milk. He submitted the results of examining samples of pasteurised milk in all parts of the country, which indicated that pasteurisation as at present carried out was anything but satisfactory. Prof. Beattie went on to quote the very conflicting results obtained by various observers as to the thermal death-point of the tubercle bacillus in milk, and expressed his doubt as to whether 30 minutes at 145° F. would render milk safe in this respect. Capt. S. R. Douglas (Medical Research Council) and Dr. R. Stenhouse Williams (Reading Institute) expressed the same doubt. Dr. Thomas Orr (Ealing) spoke in favour of the "positive holder" apparatus and considered that milk held at 145° F. for 30 minutes was good commercially and safe for the consumer. He quoted the results of Dr. F. W. Campbell Brown, of

Aberdeen,[1] which showed that 30 minutes at 145° F. or 5 minutes at 163° F. would kill the tubercle bacillus in milk. Dr. Stenhouse Williams emphasised the need for the education of the workers, whether in the cowshed or in the milk dealer's premises. Good apparatus alone was not sufficient; it must be handled by people with knowledge.

Biochemical Changes.

Prof. F. Gowland Hopkins (Cambridge) dealt with enzymes, immunising bodies, and vitamins. Some of the enzymes appeared to be of bacterial origin. They seemed to be rather accidental than essential constituents of milk. Their action was slight, we did not know that they were of any use nutritionally, and their destruction in pasteurisation appeared to be unimportant. The immunising bodies were of no use to the human species, though their presence in milk was one more argument for breast-feeding. The three or four vitamins were all present in milk, nicely balanced, and in quantity leaving little margin of safety. Only vitamin C was likely to suffer from heating processes and could easily be compensated for. He did not favour pasteurisation, as even if there was no proved biochemical harm, his work gave him a bias in favour of altering foods as little as possible. Dr. Harriette Chick (Lister Institute), following Prof. Hopkins, referred to a New York outbreak of scurvy as a result of the temporary abandonment of orange-juice among babies fed on pasteurised milk, and which was ended by the resumption of the orange juice. She emphasised the danger of repeated pasteurisations, instancing her experience in Vienna. Dr. S. S. Zilva (Lister Institute) mentioned that vitamin C was less easily destroyed by heat than was at one time thought, if alkalinity and oxidation were provided against.

In the concluding general discussion Dr. Eric Pritchard, summing up, thought that the views expressed indicated that the changes caused in milk by pasteurisation, as defined by the new regulations, were unimportant, and this was entirely in accord with his own experience.

Advance or Makeshift?

Dr. W. G. Savage (Somerset) said pasteurisation was a short cut in public health and a confession of failure. He hoped the recent agitation for cleaner milk would not be discouraged. The trade was up against the dilemma, "what is safe is not nice and what is nice is not safe." None of these apparatus was fool-proof. There were three cardinal points if pasteurisation were adopted as a temporary expedient. These were: (1) Efficient control, (2) a guarantee against repeated pasteurisation, (3) no hindrance to progress in obtaining better milk. Prof. H. R. Kenwood (Stoke Newington) said more knowledge was needed. Conflicting views were partly due to the loose use of the term "pasteurisation." He thought Prof. Beattie's results had been unsatisfactory because the milk had not been treated in the most up-to-date "holder" machines. He favoured the idea of a team of experts, appointed in coöperation with the trade, for the purpose of endeavouring to settle the points on which opinions were at variance. This suggestion was strongly supported by Lord Dawson, who took the chair during the afternoon session.

On the whole, the impression the conference left in our minds was that no appreciable advance in knowledge could be recorded since the Guildhall meeting a year ago. A third conference on the milk question was convened by the Society of Arts on April 25th last and was presided over by Mr. F. B. Acland. It is probably too soon to expect any information as to how the new regulations for pasteurisation are working, but we may venture to hope that before another milk conference is convened, the team of experts suggested by Prof. Kenwood will have something to report.

MEDICINE AND THE LAW.

Criminal Acts and Mental Deficiency.

Two cases recently tried at the Central Criminal Court appear to have had some common features but different results, which should be of interest to those who desire to see the mental condition of persons committing criminal acts carefully weighed in estimating the treatment, punitive or otherwise, to be meted out to them. Cuthbert Rice, 26 years of age, the son of a clergyman, was charged with unlawfully attempting to forge a public document, the *London Gazette* of April 4th, 1923, with intent to deceive. Having served in the army he had afterwards gone to Cambridge and had been convicted at Quarter Sessions and sent to prison for stealing from the rooms of undergraduates. He then seems to have conceived the idea that he could reinstate himself in the eyes of his relatives and friends by getting printed, in a spurious page, purporting to be from the *Gazette*, statements with regard to military honours and awards accorded to him. This obviously would be a course which could hardly escape detection. Dr. Henry Head gave evidence that Price was not certifiably insane, but that he was, in his opinion, a person of "feeble will and doubting purpose liable to fits of depression," who could best be dealt with under medical care in such an institution as Camberwell House. Dr. W. N. East, medical officer of Brixton Prison, concurred in these views, and Judge Atherley Jones, who accepted them, bound the accused over to come up for judgment if called upon, with the object that he might be treated at Camberwell House. In doing so Judge Atherley Jones said that the law only enabled the court to order the detention of persons as mentally defective who had shown such deficiency from birth, or at an early age.

In another court the Recorder had before him recently the case of Doreen Taylor, 20 years of age, said to have been a domestic servant, who had committed perjury in connexion with the arrest of two young men, having witnessed the occurrence in the street. Her evidence, which involved grave charges against the police, was designed to secure their release, and was clearly of a nature to cause investigation. She had also described herself as a waitress, giving her alleged address, and the untruth proved easy to bring home to her. Dr. J. H. Morton, of Holloway Prison, said that she had threatened to commit suicide, and was in his opinion mentally deficient but not certifiable. She had committed thefts of suit cases and other articles, of which she was also convicted. Sir Ernest Wild, in sentencing her to imprisonment amounting to nine months with hard labour, told Taylor that her career had been deplorable and that the only thing to teach her was "a hard, sharp sentence."

There appears to be some inconsistency between the treatment accorded to Rice and the "hard, sharp sentence" which is to teach Taylor to do better, whatever the differences may be in their mental condition and other circumstances. No doubt the former had relatives who could take charge of him, and the latter had not, but that hardly seems to relieve the State from a duty to provide in such cases as hers something more likely to prove beneficial than prison and hard labour.

An Indecent Exhibition Closed.

Sir Chartres Biron commented in scathing terms upon the conduct of Laurent Wynant, a Belgian, and Victor Luxemburg, a Pole by birth and a British subject by naturalisation, summoned recently at Bow-street police-court for being concerned in exposing in Charing Cross-road an indecent exhibition consisting of wax models of human bodies and of parts of them, and anatomical specimens preserved in alcohol. Sir Chartres Biron expressed himself as having been doubtful on two points only: whether he should order certain exhibits to be destroyed, and whether, having regard to the employment of a girl, 15 years of age, to sell catalogues inside the exhibition, he ought not to send both defendants to prison. Wynant had informed the authorities of the kind of exhibition he was opening, which might tend to indicate his good faith; Luxemburg, who had been said by his counsel to be a member of the London Chamber of Commerce as well as a person proud of his new nationality, had shown his commercial instinct by letting the premises, of which he was the landlord, to Wynant, the owner of the exhibition, for a rental of £50 a month, or 28 per cent. of the takings, whichever was the greater, with a stipulation that he was to have immediate possession if the police interfered. "Such," said the magistrate, "is the business instinct of this patriotic Britisher, and in those circumstances I have not the slightest hesitation in convicting him as a rogue and a vagabond." The summons for an order to destroy the exhibits was adjourned sine die on the understanding that they would be taken out of the country, and both defendants were fined the full penalty of £25, and ordered to pay £10 10*s*. costs.

---

[1] THE LANCET, August 18th, 1923, p. 317.

A case closely parallel occurred in London in 1903,[1] when Desirée Spitzner and Leon Dekaesmaker had their case adjourned at the Central Criminal Court to give them an opportunity to remove out of the country the contents of "Madame Spitzner's Great Museum," which, like the one referred to above, cloaked under an exhibition of anatomical models in wax what THE LANCET described as "a catch-penny appeal to the prurient." Chief Justice Cockburn, in 1868, gave a definition of "obscenity" which still holds good, when he said, "The test of obscenity is this—whether the tendency of the matter charged as obscenity is to deprave and corrupt those whose minds are open to such immoral influences and into whose hands a publication of this kind may fall."

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Dissolution of the Dublin Board of Guardians.

THE Ministry of Local Government, after a protracted inquiry by one of their inspectors into the working of the Dublin board of guardians, recommended the replacement of the board by a paid commissioner. In the letter from the Ministry to the board announcing this decision, the Minister notes that although the board consisted of 72 members, its work was mainly carried out by some 25, and the sporadic attendance of the negligent members nullified the efforts of those who were devoted to their duties. The inspector, in his report, commented adversely on the condition of the dispensaries belonging to the board. They were both dirty and cold. In one instance the inspector had failed to find either doctor or porter on the premises during dispensary hours. In all cases the inspector found measure glasses in a dirty state. Medicine seemed to be thrown about in an untidy manner; in many cases poison presses were not locked. There was also neglect in dealing with boarded-out children, and with children at nurse under the Children Act. Evidence showed that an actual system of child-farming had been indulged in. A case where six babies died in two weeks painfully illustrated this. The unregistered nursing home was an equally grave danger. There would appear to be serious need of legislation under which nursing homes, private or otherwise, would be compelled to register before accepting the care of any child. In the administration of the workhouse and its hospitals neither the master, the matron, nor the doctors could exercise an adequate control. The doctors were powerless to enforce discipline, and complaints received such scant attention that it was only in very exceptional circumstances that the board was troubled with them. The guardians had not exercised proper management in connexion with hospitals, dispensaries, outdoor relief (particularly in rural areas), stores, staffs, appointments, discipline, admissions, and discharges. The inspector sums up his views on the work of the guardians in saying that the affairs of the union were not managed, but merely transacted.

In dealing so drastically with the board of guardians under its jurisdiction the Ministry probably intends its action to stand as a serious warning that negligence or inefficiency by boards of guardians will no longer be tolerated.

Vaccination in Ireland.

The Free State Government is wisely alive to the danger of importing small-pox from England, and is taking steps to safeguard the health of the country. In answer to a question in the Dail last week, the Minister for Local Government stated that, owing to prevalence of disease in England, medical officers of the ports had been warned, whilst the vaccination authorities in the Saorstat had been advised of the danger. In one or two districts the number of defaulters was high, but the matter was being carefully watched. If the local authorities failed to take adequate measures to ensure the safety of the public, steps would be taken to compel them to do so.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Unsettled Conditions in the Medical Profession.

AT present the members of the medical profession are suffering from the effects of serious unrest caused by internal and external factors. As has been mentioned in a previous letter (THE LANCET, June 23rd), a serious split occurred in the "Economic Organisation of Doctors." The hospital medical staffs endeavoured to construct an organised corporation of their own, the aims of which would not infrequently have clashed with the aims of the older corporation. At the present time, when combination of forces and uniform action are essential, such disruption is bound to spell ruin for both parties. Partly under the influence of this reflection, partly from purely economic considerations, numerous hospital doctors have returned to the mother organisation, and there is reason to expect in due season a re-union of the two sections. Another source of disquiet has arisen in the profession through a decision of the Government to extend the scope of the compulsory insurance against illness. All persons receiving salaries or wages are to be entitled to free medical help, without any restrictions as to the absolute amount of their income, the insurance to cover also their families if they pay the premium for them. The profession hitherto has not been asked to give its opinion on this scheme. But although "free choice of doctor"—an old demand of the profession—has been granted, this is only regarded as a slight concession to medical feeling. The Government will have to come to terms with the representatives of the practitioners, otherwise the Bill might become law—but the doctors will not coöperate. Nevertheless, earnest attempts at negotiation will be made by the leaders, as the opportunities for private practice will be cut down almost to nil, if, for example, a manager of a bank, a director of a business concern, or the family of a stock exchange broker may call in an "insurance" doctor.

In the course of preparing the lists of voters for the election of the Medical Council, a survey of all practitioners in this country was ordered by the Board of Health. This was necessary, as since the disruption of the former empire numerous medical men have settled down in Vienna and elsewhere, who are not citizens of the Republic. The number of defaulters was very small, however. The new council will be elected under the New Medical Act, which gives much more discretionary power to this body, and endows it with disciplinary jurisdiction over the doctors in a large number of more or less serious offences against medical ethics. In the face of the progressing pauperisation of the profession one cannot wonder that illness and old age are objects of real terror for the doctor of to-day. Strenuous efforts to obtain insurances against these contingencies on the part of the organisation have hitherto been fruitless. The Central Medical Council nominated a special committee last year to study the problem, and since its suggestions were not practicable, private enterprise has set to work to construct an adequate scheme. The latest proposal deals not only with insurance against illness and old age, but also with insurance for widows and orphans of practitioners. Further, it demands that membership of this medical union be made compulsory by law. The difficulties of the variations and fluctuations of our exchange rate might be overcome by calculating—and paying—fees in a stable exchange rate, preferably on the gold system. Experts are now studying this scheme, which entails the payment of about a pound sterling monthly from each doctor. This expenditure seems, however, to be very heavy for the average income of an Austrian doctor. At all events, the problem is an acute one, and some solution must be found if serious disaster is to be avoided.

Appointment of a New Director of the Chemical Institute.

The Ministry of Education has recently appointed Prof. Fr. Faltis, former head of the Chemical Institute in Graz, to the vacant directorship of the Pharmaceutical Chemical Institute of the Vienna University. Prof. Faltis is a graduate of Vienna, and before he was called to Graz was for some years at the head of the School of Apothecaries in Vienna. Whilst working there he published some important contributions on the chemistry of alkaloids. His new position will enable him to emphasise to students of medicine the importance of studying the physiological effects of modern pharmacology.

Scarcity of Cadavers for Anatomical Studies.

The Vienna Anatomical Institute is faced with a serious difficulty as the students cannot be given the human material required to obtain a fundamental knowledge of anatomy. In 1921–22, the Institute received 78 whole bodies and 79 dissected cadavers of infants. In 1922–23, the supply had dropped to a total of 31 bodies, whilst this year only one single corpse has been available, and there are over 1000 students who expect to do dissecting work at the Institute. Two years ago the scarcity was very marked, as no more than two corpses could be handed over to a dissecting group of six men per half-year term, against four or five corpses 10 to 15 years ago. At present not even one body is available for such a group, and when the last one of the bodies preserved in the cellars of the Institute has been dissected, the directors will be obliged either to close the Institute entirely or to cut down the work drastically. The reason for this scarcity can be explained only in part by the diminution of the number of patients in the hospitals owing to the reduced size of the State. The chief reason is the formation of a society which undertakes the burial of unclaimed bodies in the hospital mortuaries. Formerly, the corpses were handed over to the anatomical theatres and then buried after dissection. In vain the dean of the faculty and the heads of the anatomical institutes have pressed the matter with the Ministry of Education. There are very high ecclesiastic influences directed against the dissection of human bodies. Such influences are stronger than one would expect and counteract all endeavours by the faculty to adjust matters. At present negotiations between the dissecting departments of hospitals and the anatomical institutes are on foot to arrange an exchange of material, but this is at best only a temporary adjustment of a condition which must be cleared up by legislation, if Vienna is to retain her position in the medical world.

Marked Decrease in Venereal Disease.

A report of the Board of Health dealing with the effect of prophylactic measures states that the morbidity from venereal disease, especially gonorrhœa, is rapidly diminishing in Vienna. Striking figures are given by the out-patient departments of hospitals, and from the dispensaries instituted by the Krankenkassen (sickness insurance clubs) of the workmen. Whilst in 1918 more than 30 per cent. of the patients of the dermatological departments both of hospitals and clubs complained of sexual diseases, in the first half of 1923 the percentage went down to 5 and under, the total number of patients remaining about the same. This means, in other words, a decrease of over 80 per cent. in the incidence of venereal disease. Also in private practice we find similar conditions. Whilst three to five years ago the waiting-rooms of venereal specialists were thronged with members of our "best" society, now no more than 5 per cent. of better-class patients suffer from lues or gonorrhœa, a fact which is clearly reflected in the precarious financial position of many dermatologists of repute. The chief credit of this welcome improvement in public health is due to the efforts of Prof. Finger and Prof. Tandler. To combat the former alarming spread of venereal disease Prof. Finger suggested the institution of a large number of free dispensaries on the one hand and public instruction on the other. Prof. Tandler, during his tenure of office as Minister of Health, carried out these proposals, and with much energy organised in every Vienna district, as well as in every large municipality or industrial centre, an "ambulatorium" (dispensary) where qualified specialists gave free medical help to all persons applying for treatment. No questions were asked, no fee required, and the hours of attendance were after working hours (5–8), so that no loss of valuable time was entailed by the patient—a point of consideration often neglected in hospitals. The leading idea was prophylaxis against disease, and immediate treatment in case of disease. By widespread public enlightenment—lantern lectures, instructive leaflets, teaching of pupils in higher schools—the public have learned to regard venereal disease not as a thing to be ashamed of, but as a condition requiring proper treatment, just as any other infection. The 21 evening dispensaries in Vienna have now, by their own work, rendered themselves almost superfluous. Seven have been closed, and it is hoped that shortly the ordinary institutes—viz., clinics and hospital departments—will be sufficient to deal with the existing cases.

BUCHAREST.

(From our own Correspondent.)

Pre-Matriculation Examinations in the Universities.

The Minister of Public Instruction, Mr. Anghelesen, has instituted a new measure in the universities of Roumania. The universities must now themselves examine students before allowing them to matriculate. This regulation has caused much dissatisfaction among the students who passed their school-leaving examinations only a few months ago. As yet the university examining board has not been too severe, judging from the fact that, for instance, in Cluj only a few out of 90 applicants were rejected. The board lays the chief stress on the general knowledge and intelligence of the students. The subjects of examination are: Roumanian language and literature, history, geography, and constitution; in the medical faculty anatomy and physiology are added. It is a general principle that only such students are matriculated as are able to understand the lectures in the Roumanian language. The professors, however, appreciate that almost all applicants claim Hungarian as their mother tongue, and allow them to answer in Hungarian, if they cannot express themselves in Roumanian. It is an undeniable fact, however, that this new system, which is unique in Europe, has considerably decreased the number of first-year students in the Roumanian universities. Foreign applicants with maturity certificates of foreign schools are exempt from the admission examination, lest foreign universities should reciprocate by applying the same measure against Roumanian students. As a consequence of this new measure numerous Hungarian and Saxon students (there are very many Saxons in Transylvania) have matriculated in foreign universities. Even Roumanian students have gone to Italian and French universities to evade the admission examination. It is remarkable that in the medical faculty of the Cluj University out of 82 first-year students there are altogether only three Christian Hungarians and four Jewish Hungarians, although the majority of population in and around Cluj consists of Hungarians. This can be attributed to the frequent demonstrations against the Jewish and Hungarian students in the course of the last year, when, following serious disturbances, the university had to be closed for a whole session.

Excessive Taxation of Medical Men.

Bitter feeling has been aroused among the doctors of Roumania through excessive taxation. Under the recent law relating to the standing of professional men, lawyers and doctors have been placed in the same category as retail merchants, and a tax of 16 per cent. has been levied on all professional income. The income of the physician is fixed by a committee consisting of four representatives of the financial authorities together with one medical man. The voice of the profession is thus easily overborne, and taxes are imposed which simply spell ruin to the rank and file of the doctors. The injustice of this burden is all the greater as the basis of income on which the 16 per cent. tax is paid is calculated on the physician's total earnings during the past year, and no allowance is made for expenses such as rent, household, carriages, instruments, journals, &c., as was done in former years. The various medical associations of the country have united in a movement to demonstrate against this crushing imposition, and the Government has been threatened that, unless the taxes are reduced, all private doctors of the country will cease to give gratuitous medical service to the poor. Up to the present there has been no reduction in the income-tax, but a new tax has been devised, called the "Sign-Board Tax," by which a levy is made on every professional sign or name-plate. Doctors in the outlying districts are heavily penalised in that name-plates in any other language than Roumanian are taxed 60 or 80 fold. And considering that in Transylvania, Bukovina, and Bessarabia there are about 2500 doctors with an entirely non-Roumanian speaking clientèle, it is easily understood that this order has caused great dissatisfaction. For instance, in Arad, a flourishing industrial and commercial town in Transylvania, the tax upon a name-plate or sign bearing Hungarian words amounts to 8000 lei, which is equivalent to the doctor's total fees for more than 100 visits. Thus a young practitioner, newly settled, who puts up his plate stating his consultation hours, &c., in the language of the people on whom he is dependent for a livelihood, finds his returns for at least two months in a year swallowed up by this tax. Also he is fortunate if he is paid for 100 visits in two months. A deputation was sent to the Minister of Finance to urge that the language of the universities be not regarded as "foreign." Some optimists hope that the Minister may adhere to the statutes of the Versailles Peace Treaty, which provides for the unrestricted use of their mother tongue by all sections of the nation.

Doctors and the Telephone.

The Roumanian telephone authorities have two separate scales of charges for subscribers, 3000 and 1000 leis (nominally £120 and £40) respectively. The former charge is made to business men, lawyers, and physicians, while the latter applies to private persons. The medical faculty of Roumania has protested several times at this classification of the profession along with tradespeople, and has emphasised the benefits which accrue to the public through the doctor's telephone. All protests, however, have been in vain, and the Minister refused the appeal of a large medical deputation which requested the reduction of telephone charges. As a sequel, the medical men of Bucharest resolved to make a "telephone strike," so that on Nov. 10th no doctor responded to any call over the telephone. The general public fully appreciates the position of the doctors, and cannot understand why a physician should pay as much as a wholesale merchant or a bank, when a capitalist living on the dividends of his capital may have a telephone for a third of the sum the doctor has to pay. Although the "strike" made a deep impression on the authorities, as yet no reduction in the telephone charges has taken place.

CENTENARY OF THE LANCET.

To the Editor of THE LANCET.

SIR,—I have pleasure in informing you that the Council of the London and Counties Medical Protection Society, Limited, at its meeting on Nov. 21st, on the proposal of our President, Sir John Rose Bradford, seconded by our Chairman of Council, Dr. C. M. Fegen, unanimously passed the following resolution:—

> "The Council of the London and Counties Medical Protection Society, Limited, heartily congratulates THE LANCET on the completion of its hundredth year, and takes this opportunity of expressing its appreciation of the high literary character of THE LANCET, and of the vigour with which it upholds the best traditions and protects the true interests of the medical profession."

I am, Sir, yours faithfully,
HUGH WOODS,
General Secretary.
Nov. 22nd, 1923.

EPIDEMIC DIAPHRAGMATIC PARALYSIS.

To the Editor of THE LANCET.

SIR,—Much interest attaches to the recent outbreaks of disease in the United States, of which one is referred to in THE LANCET of Nov. 17th. Various names, including that of "devil's grip," appear to have been bestowed upon this "new disease," but that of "epidemic diaphragmatic paralysis" seems to have found most favour, on the *lucus a non lucendo* principle, since the clinical condition is recognised as one of diaphragmatic spasm. It seems pretty clear that the outbreaks form an epidemiological link between influenza of the dengue type (with a bileptic temperature curve) and epidemic hiccough, which, as is now generally recognised, "runs into" epidemic encephalitis and myelitis. As a matter of fact, in America, the new disease has already been identified with the Virginian epidemics,[1] at the time thought to be dengue, but lately regarded as amongst the epidemiological prodroma of the great pandemic of 1889–90.[2]

Dr. H. W. Leatham's lucid account, in your issue of last week (p. 1163), of an outbreak of similar nature is then of peculiar interest. At the Prince of Wales's General Hospital last month I saw two cases of the same type, and the confident opinion was then expressed that we should shortly have accounts from rural districts of such outbreaks as that now described by Dr. Leatham. At the time that the two cases I speak of were seen, there were, in the same wards, a case of "heliotrope pneumonia," a case of severe gastro-intestinal influenza followed by jaundice, and several cases of diverse nervous types. More recently a woman has been seen with lethargy, with double ptosis, with hand and foot pains and hæmorrhagic blebs of the "acrodynia" type who, at the post-mortem examination, displayed an acute hæmorrhagic encephalitis. Her illness commenced with "influenza" and broncho-pneumonia. Now, when one observer in a large town or city sees, almost simultaneously, single or sparse cases of these different types, and we begin to have reports from rural districts of outbreaks conforming to one or other of these types, it is difficult not to think and speak of epidemic influenza. Our interest is quickened when, as now, we read of cattle disease spreading here and there, and we remember that, for six or nine months past, reports have arrived, if not from throughout the world from China to Peru, at any rate from Bombay to Brazil, of strange and new epidemics, somewhere thought to be dengue, somewhere thought to be influenza, but everywhere "baffling the doctors" who generally agree that it is indeed a "new disease." It was thus in 1888, and it was thus in 1917 and 1918.

---

[1] Brit. Med. Jour., 1888, ii., 1176.

[2] Cf. F. G. Crookshank, Influenza, p. 460.

It will be interesting to see what is now going to happen. It may be that we should expect such a revival of influenza as has not happened since 1919, but as did happen five or six years after the pandemic of 1889–90. It may be, on the other hand, that we are in for such a 20 or 30 years of influenza, its congeners and allies, as followed the pandemic of 1831. During great part of that time, in Creighton's words, the influenza years came "thick and fast." Again, it may be that nothing in particular is going to happen.

What, however, does seem desirable is, that frequent reports such as that of Dr. Leatham should be made by those who enjoy his opportunities—for it is in rural districts that *outbreaks* are best studied. In towns grouped cases are often missed, for the like individuals are often seen by different doctors, who do not recognise the epidemiological matrix, as it were, in which maladies, apparently so diverse as a pneumonia, a jaundice, an encephalitis, a gastroenteritis, or a tonsillitis are embedded. At any rate, we can try to form some general idea of what is foreshadowed by the "certain liveliness" now in evidence in the epidemiological field.

I am, Sir, yours faithfully,
F. G. CROOKSHANK.

Wimpole-street, W., Nov. 26th, 1923.

THE ALBUMINURIA OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—I am afraid Dr. J. W. Russell (THE LANCET, Nov. 17th, p. 1110) has misinterpreted the meaning of my letter (Nov. 10th, p. 1057). So far from contending "that the albuminuria of pregnancy is not likely to be explained on mechanical grounds to any great extent," my contention is that this condition is not likely to be explained on any other ground. Prof. F. Cook showed (Nov. 3rd, p. 1008) that the albuminuria of pregnancy may be at times of unirenal origin, when perhaps it is due to obstruction of the left renal vein. My point was that since this albuminuria is more often bilateral, and obstruction of the right renal vein cannot be so well advanced as that of the left as a cause, we are led to consider obstruction of the *renal capillaries* by *physical causes* as an explanation. Dr. Russell, perhaps, will admit that if obstruction of the renal vein causes albuminuria, obstruction of the renal capillaries—e.g., by a compression of the whole organ—may also do so. We have, indeed, proof that this is so. Thus, if the ureter be clamped and after a while released, albumin is present in the urine secreted. (In this and the following examples the capsule of the kidney acts as container.) In hydronephrosis the urine from the affected kidney contains albumin. Clamping the ureter, as Ludwig (1864) showed, causes a diminution in the flow of blood from the corresponding renal vein. The distension of the uriniferous tubules thus hinders the blood-flow through the renal capillaries. The diminution is so great that if the condition persists atrophy of the renal substance occurs. This cannot be explained by the distending pelvis of the kidney obstructing the renal vein.

It is generally held, I believe, that the albuminuria of pregnancy is due to a toxin. If this be so, it must be admitted as remarkable that the albuminuria of pregnancy, as Prof. Cook states, is "usually unaccompanied by any other deviation from the normal with the possible exception of œdema"—either "clinical" or "biochemical." Certainly, many pregnant women with albuminuria appear, and say they feel, in excellent health—as we know, the albumin is often only discovered by routine examination of the urine. Nor is this conception in line with the known fact that albumin often appears for the first time during labour; we cannot believe a specific poison, for the first time in the pregnancy, is let loose during or by this act. Similarly, the disappearance of the albumin by putting a pregnant albuminuric to bed, dieting and purging her, does not support this conception. It is, indeed, supposed that by such measures a toxin is eliminated and that thus the albuminuria is cured; but this is not the only or the more reasonable explanation. Unfortunately, it is not yet grasped that the physical forces of the body are reduced by such measures, and that circulatory changes of importance in organs by these means alone are determined. Muscular activity—e.g., tonus—(on which the blood pressure and other body pressures depend) is not the same on a starvation as on a full diet, or when resting as when working; how, then, as long as such forces are omitted from consideration, can we come at the truth? If such argument is applicable to the albuminuria of pregnancy it is, I submit, applicable to the albuminuria of other types—especially to those imputed to be physiological. Dr. Russell believes that many cases of albuminuria (of postural and other origin) will be shown to have a "renal pathology." The regret is that the teaching of that great natural experiment—pregnancy—has not as yet shed its light on internal medicine.

I am, Sir, yours faithfully,
R. H. PARAMORE, F.R.C.S. Eng.

Brook-street, W., Nov. 17th, 1923.

$*_*$* Mr. Paramore's letter was referred to Dr. Russell, who replies: "My apologies are due to Mr. Paramore. I was thinking entirely of 'unirenal' albuminuria, and should have used that adjective instead of 'mechanical.' But my slip has elicited a very interesting letter, and may therefore be the less regretted."—ED. L.

THE IMPORTANCE OF NASAL SINUS INFECTIONS.

To the Editor of THE LANCET.

SIR,—In reference to the two valuable papers recently published in THE LANCET on unrecognised maxillary sinus disease, the two following cases are worth record. In neither case had the presence of sinus empyema been suspected. Both show the paramount necessity for complete examination.

1. A man, aged 51, was sent to me for persistent pharyngitis. He had also a general septic rash, suffered from dyspepsia with occasional nausea and retching on waking in the morning, and complained of not having "felt himself" for some months. The breath was very offensive. He had undergone operation, under local anaesthesia, for nasal polypi (?) 11 months before consulting me. Anterior rhinoscopy showed a considerable turgescence of the left middle turbinal, and the electric nasopharyngoscope revealed enlargement of the posterior ends of the left middle and both inferior turbinals. There was no pus in the nasal chambers, nor did any appear with the head in the drainage position. There was marked pharyngitis, especially in the left lateral recess. There was some septic bridge-work on the left upper alveolus. Transillumination showed complete absence of the crescent on the left, and an X ray photograph proved both frontal sinuses to be clear, while the left antrum was obscured by a strong shadow. The left nasal wall of the antrum was punctured under general anæsthesia and the sinus washed out. The muco-pus it contained was extremely thick and stinking. The opening was enlarged by the removal of the nasal antral wall in its whole length. Recovery was uneventful, and two months after the operation the patient reported himself as "quite recovered."

2. A woman, aged 57, consulted me for recurrent aching in the right ear, and pain (without tenderness) in the course of the Eustachian tube. The symptom had been present, on and off, for about five months. Nothing abnormal could be

detected in either ear, either upon inspection or by functional tests. Beyond the admission of a feeling of general ill-being no other symptoms could be elicited. The upper teeth had been removed some years earlier and the patient was wearing a complete upper case. On examination of the nose there was a marked turgescence of the right middle turbinal. No pus was seen and none appeared after placing the head in the draining position. Transillumination showed a clear crescent on the left side, complete absence on the right. The antrum was washed out through a puncture in the nasal wall and recovery was rapid. There was a moderate quantity of fairly thick muco-pus. The ear pain appears to have been relieved immediately the tension in the antrum ceased.

In both cases no pus could be found in the nasal passages, nor was there any headache, although that symptom was specially inquired for.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY, F.R.C.S. Eng.,
Consulting Aural Surgeon to the London County Council and the St. James's Hospital, Balham, &c.

Welbeck-street, W., Nov. 20th, 1923.

NASAL SINUSITIS IN PHTHISIS.

To the Editor of THE LANCET.

SIR,—I agree with Dr. P. Watson-Williams that the wording of my remarks on the occurrence and production of laryngeal signs is too loose unless these remarks be regarded, not as a general statement of the question applicable to all forms of sinusitis, but as applying solely to sinusitis which simulates pulmonary tuberculosis. Dr. Watson-Williams thinks I attach too much value to the presence of pus and invites my attention to the more exact methods of investigating the sinuses by examining their contents microscopically. I frequently use the apparatus that he designed for this purpose and have found it most valuable. It opens up a field of research on the question of where the normal reaction of the mucous membrane to organisms extracted from the inspired air, and spreading from continuity of the mucous membrane to the sinuses, may be said to end and where sinusitis may be said to begin. It is most serviceable in conditions which may be described as sinus infection of a chronic nature, rather than sinusitis in which the organisms become symbiotic and produce toxic absorption leading to arthritis, without producing changes which can be recognised clinically as sinusitis. I do not think, however, that such conditions of the sinuses as are detectable only by microscopical examination can produce changes of such a nature that the secretion of muco-pus is sufficient to form a sputum and lead to simulation of pulmonary tuberculosis, though I agree that in some cases the pus mixes with watery solutions, if these are employed for irrigation, for which reason I now employ liquid paraffin.

Dr. Watson-Williams takes exception to my statement that frontal and ethmoidal sinusitis do not complicate the diagnosis of pulmonary tuberculosis and that sinusitis affecting the sphenoid has not been met with except in the presence of other sinusitis, and I agree that this statement is too wide in application if cases detectable only by microscopical methods are included. All that I am entitled to say is that out of over 200 examinations of the sinuses in patients with sinusitis in whom pulmonary tuberculosis had been diagnosed but in whom the diagnosis was in doubt, the sinusitis affected the maxillary and less commonly the maxillary and posterior ethmoidal and sphenoidal sinuses, and that where frontal sinusitis was present the patient complained of pain, the significance of which had been recognised by the physician examining the case. I do not think that sinusitis with secretion of muco-pus will be found to affect the anterior ethmoidal group unless there is at the same time some degree of maxillary sinusitis.

Dr. W. C. Rivers's letter in THE LANCET of Nov. 17th commenting upon my paper suggests differences of opinion on this question, which, from a perusal of his book to which he refers me, appear to be more apparent than real. He quotes Dr. Dan McKenzie as attributing purulent ethmoiditis to 10 out of 102 consumptives, but omits to quote the remainder of the same paragraph in his book (p. 142), in which he states that Skillern found secretion or pus in the washings of the antrum in 11 out of 100 tuberculous individuals. On p. 128 of the same book Dr. Rivers writes: The strong affinities of the nasal atrophy of consumptives to ozæna count against Moure's conception of it as a special rhinopathological condition of itself peculiar to *tuberculous* patients," which contradicts the statement of this author's views in his letter. Again, in his letter Dr. Rivers deprecates any packing of nasal sinuses in consumptives with antiseptics, whereas in his book (p. 132) he states that it is his practice in ozæna (in consumptives) to pack the nose with double cyanide ribbon gauze. I could give other instances, but I think I have said enough to show that the points of disagreement are only apparent. If during the course of the six years since the publication of his very carefully written book, Dr. Rivers has made observations that have caused him to alter the views there expressed, as his letter would suggest, I should be glad to learn of them.

I am, Sir, yours faithfully,

Birmingham, Nov. 22nd, 1923. A. LOWNDES YATES.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. F. C. B. Gittings is placed on Ret. List with the rank of Surg. Capt.

Surg. Lieut. F. L. H. MacDowel to be Surg. Lieut.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Maj. G. W. Heron (secd. Foreign Office) retires, receiving a gratuity, and is granted the rank of Col.

K. Fletcher-Barrett to be Lt. (on prob.) and to be secd.

Temp. Capts. relinquishing their commns. and retaining the rank of Capt.: E. O. Gilkes and J. McGrath.

REGULAR RESERVE OF OFFICERS.

R.U. Rif.—Lt. J. M. Semple, late R.A.M.C., to be Lt.

TERRITORIAL ARMY.

Maj. P. Moxey, from General List, to be Lt.-Col.

ROYAL AIR FORCE.

J. E. Cox is granted a temporary commission as a Flight Lt.

CATHERINE GLADSTONE HOME.—This annexe to the London Hospital was officially opened at Mitcham, Surrey, on Nov. 19th, by Sir William Joynson-Hicks. The home, which is most comfortably furnished, in delightful surroundings, contains some 50 beds for women and children convalescents. Mr. William H. Baker, chairman of the Marie Celeste Samaritan Society of the London Hospital, described the gift of the Catherine Gladstone Home as a fitting climax to the long-standing interest of the Gladstone family in the hospital, which dated back to the cholera epidemic in 1866. Mrs. Gladstone, during the epidemic, was so touched by the plight of the children who were orphaned that she opened a home for them at Woodford, which was later removed to Mitcham. After her death the home was administered by trustees, who, a year ago, suggested that it should be handed over, with its endowments of about £1200 a year, to the London Hospital. As the House Committee could not meet the cost of upkeep the Samaritan Society came forward with a generous offer of help, and extensive alterations were made to meet modern requirements. Altogether about £8000 has been spent on equipment. In referring to the need the home would meet in hospital work, Sir W. Joynson-Hicks said that in the London Hospital a patient might have a better chance of recovery than in many nursing homes. In every great hospital the scientific side was coming to the front, and the great central hospital became more and more the place for diagnosis. The annexes would be the places where the cures were carried out, thus relieving the list of people waiting for admission. A bed cost £5 5*s.* a week in the London Hospital, and at Mitcham it only cost £2 a week. He saw in the future the London Hospital becoming a department for accidents and diagnosis, and the main work of healing conducted on the outskirts of London.

THE GENERAL MEDICAL COUNCIL.

The winter session of the General Medical Council was opened on Nov. 27th, Sir Donald MacAlister presiding.

President's Address.

The President began by regretting the untimely death of the assistant secretary, Mr. A. J. Cockington, who for 35 years was a member of the office staff. "None was more loyal and devoted," said the President. "His knowledge of our proceedings was encyclopædic in its range and accuracy. In my experience, and I believe in that of many other members and officers of the Council, though his knowledge was never obtruded, it was never found wanting when need arose. During the absence of Colonel King on active service, Mr. Cockington, as deputy registrar, carried on his shoulders the heavy administrative burden that the Council's multifarious war work entailed. He spared neither time nor labour in the effort to carry it through successfully, but I fear that his success was gained at the cost of permanent damage to his health."

Tributes to the Dead.

The President then recalled to memory two former members of the Council who had both recently passed away. Mr. Thomas Pridgin Teale and Dr. David White Finlay. The first, whose father was one of the original members appointed by the Crown in 1858, himself served as a Crown member for 24 years, from 1876 to 1901. "As a surgeon, sanitarian, teacher, and man of science," said the President, "his was a venerated name. Dr. David White Finlay, who was at one time inspector of medical examinations, was a member of the Council from 1901 until 1911. He won," said the President, "a high reputation as a physician, and a teacher of physicians, both in London and in Aberdeen. After retiring 12 years ago from the Regius chair in the latter university, he returned to the Clyde which he loved, but notwithstanding his advanced age, he served as commandant of a Red Cross hospital in Glasgow during the war with characteristic thoroughness and efficiency."

Medical Education in India.

Sir Donald MacAlister continued: The Executive Committee, thanks to the good offices of Sir Norman Walker, had the privilege yesterday of meeting Lieut.-Colonel Needham, who has been appointed by the Indian Government and approved by the Council as the official inspector of the Indian universities and Colleges of medicine, and of discussing with him the many important questions that have arisen regarding the conditions of recognition, for the purposes of the British Register, of Indian medical degrees. The Government has placed him on special duty in order that he may attend the meetings of the Executive Committee at this session, and discuss these questions with us in person. The Council will, I know, be glad to welcome him here, on account of the distinguished position he holds in the Indian Medical Service and of the responsible functions he has undertaken for the benefit of medical education in India. I trust that during the week he may obtain all such information concerning the Council's methods and procedure as he desires in furtherance of his efforts to coördinate our standards in all the essential branches of professional training for registrable qualifications with the standards hitherto current in the Indian universities and colleges. We in our turn will profit by learning from him what improvements in their educational arrangements have been already made or are desiderated by these important bodies, in order that the whole course of study and examinations for the degrees they desire to be registrable in this country may continue to justify our official recognition. The reports presented to the Executive Committee, and published with the minutes of last June, show that in regard to certain essential features of their course the universities themselves are fully aware that improvements are necessary, even apart from the consideration of external recognition I need mention, as examples, only such matters as the excessive number of students admitted to the medical colleges of certain of the universities; the limitation, to two years, of hospital study after the examination in anatomy and physiology; and the inadequate facilities for practical training in midwifery. The Council will readily acknowledge the desire which has been manifested by the several Indian universities to remedy such deficiencies, notwithstanding difficulties due to local conditions and local organisation; but it must urge strongly the necessity of prompt and effective action on the part of these authorities, if their laudable desire is to be fulfilled within a reasonable time.

If the question were simply one of a suitable professional training for practitioners, *practising in India* under Indian conditions, the Indian Universities, Colleges, and Schools, with their special knowledge of local requirements, would naturally be the best and indeed the only judges. From this point of view India is autonomous, and the Council has neither the wish not the power to intervene. But when the Council is called on to recognise an Indian qualification for registration *in this country*, it is bound by Act of Parliament to inquire into the conditions under which any such qualification is granted. It is bound to require that the qualification shall furnish a sufficient guarantee of the knowledge and skill, in medicine, in surgery, and in midwifery, requisite for efficient practice, not in India alone, but in the United Kingdom, and in the other parts of the world with which this country has established reciprocity of practice. If it is found, in respect of any particular degree, that the guarantee is no longer sufficient, the Council would be in default of its statutory duty, and so be liable to supersession by the Privy Council, were it to continue to recognise such a degree as registrable and therefore valid outside of India.

It is on this ground only that the Council is by law entrusted with a specific responsibility as regards qualifications granted elsewhere than in the United Kingdom. It is on this ground only that it has requested from the Indian Government the special facilities for inquiry and inspection which have been placed at its disposal, and which have been so ably and sympathetically utilised, in the best interest of Indian medicine, by Lieut.-Colonel Needham. We have to await his further reports—reports, as we hope, of very substantial progress—before deciding at the next session what further steps we shall take regarding some of the qualifications granted in India.

Status of Practitioners Abroad.

The Executive Committee is continuing its negotiations with the Provincial medical authorities in Canada, with a view to formulating a uniform and comprehensive statement of the conditions on which recognition shall in future be accorded to diplomas and degrees registrable in the Dominion. A considerable measure of agreement has been reached, and the Committee expects that by next session outstanding difficulties will be removed and a satisfactory arrangement will be completed.

Communications have also been received and answered, through the Privy Council and the Foreign Office, concerning the status of British practitioners in Italy, Greece, and Turkey. There is reason to believe that the answers have been found useful.

Relation to Midwives.

We have received from the Ministry of Health a copy of an important decision of the High Court on a case in which an uncertified woman was charged with a breach of the Midwives Act, 1902. It was alleged on her behalf that she had not attended women in childbirth otherwise than "under the direction of a qualified medical practitioner," and so was not guilty of infringing the Act. Several practitioners testified that though they had not attended the women before confinement, had given no instructions to the uncertified person, and had not been present at the birth, they had attended the patients subsequently, and that thus the uncertified person had acted under their "direction." The Court ruled that in such cases there must be "a real and not a mere nominal direction." This decision will strengthen the hands of the Council in dealing with cases in which practitioners are alleged to have disregarded its warning notices on this subject, and of having "knowingly enabled uncertified women, on pretence that such women were under their direction, to attend women in childbirth, contrary to the law." Steps have been taken to make this decision known to practitioners and supervising authorities, who have made inquiries on the subject. It is probable that some amendment of the Act, setting forth in precise terms that the "direction" of the practitioner must be immediate and personal, or, in the words of the judgment, "real and not nominal," will be necessary to prevent the continuance of abuse.

Order of Business.

The inspection of examinations for dental qualifications, which you ordered to be instituted at the last session, is in progress. Reports of two or three such examinations have been received, but it is thought advisable by the Committee in charge that the series should be more complete before the reports are formally brought before you. The Council will thereby be in a better position to form a comparative judgment on methods and standards.

In accordance with precedent, most of your time, at this November session, will be occupied in hearing cases of discipline under Section 29 of the Medical Act, 1858. A number are cases of conviction by the ordinary courts; a few arise from complaints of professional misconduct in contravention of one or other of your warning notices. The Dental Board also will report to you their findings against certain dental practitioners, in pursuance of the Dentists Act, 1921. So far as I am able to gather, none of the disciplinary cases raise general questions of an unfamiliar kind, but the special points of each will, of course, require and receive your careful consideration.

THE PARLIAMENTARY ELECTION:

MEDICAL CANDIDATES.

NOMINATIONS were completed on Nov. 26th and two medical men have been returned unopposed to the House of Commons.

Returned Unopposed.	*Constituency.*	*Party.*
Sir George Berry†	Scottish Universities	Conservative.
Prof. Thomas Sinclair	Queen's University, Belfast	Conservative.

Sir George Berry, along with Sir Henry Craik—a good friend to medicine—sat for the same constituency in the last House of Commons. In his election address he expresses his intention to watch and, as far as possible, promote the special interests of the universities and particularly of the medical profession, independent of party considerations..

Prof. Sinclair, who follows Sir William Whitla in representing Belfast University, occupied the chair of surgery in Queen's College, in succession to the late Dr. Alexander Gordon, for 37 years, retiring at the close of last session. Recently he had acted as registrar and vice-chancellor in the Queen's University. He is a member of the General Medical Council and of the Senate of Northern Ireland, as well as consulting surgeon to the Royal Victoria Hospital, Belfast, the Ulster Hospital for Women and Children, the Forster Green Hospital, and the County Antrim Infirmary. He served with distinction as consulting surgeon during the war, and received the honour of C.B.

At the General Election, which takes place on Dec. 6th, the following medical candidates will seek election. Those who sat in the last Parliament are indicated by a dagger, and those who stood unsuccessfully by an asterisk.

Candidate.	*Constituency.*	*Party.*
Dr. Ethel Bentham*	Islington, East	Labour.
Dr. H. B. Bates*	Lancaster, Newton	Conservative.
Dr. W. A. Chapple†	Dumfries	Liberal.
Dr. R. Dunstan*	Birmingham, Ladywood	Labour.
Capt. W. E. Elliot†	Lanark, Lanark	Conservative.
Dr. F. E. Fremantle†	Hertford, Albans	Conservative.
Dr. O. Gleeson	Portsmouth, North	Labour.
Dr. L. Haden Guest*	Southwark, North	Labour.
Mr. Somerville Hastings*	Reading	Labour.
Dr. G. B. Hillman	Yorks W.R., Normanton	Conservative.
Sir Henry Lunn	Brighton	Liberal.
Dr. J. E. Molson†	Lincoln, Gainsborough	Conservative.
Dr. H. B. Morgan*	Camberwell, North-West	Labour.
Dr. A. G. Newell	Tottenham, South	Liberal.
Dr. R. L. Ridge	Middlesex, Enfield	Liberal.
Sir Sydney Russell-Wells†	London University	Conservative.
Dr. Alfred Salter†	Bermondsey, West	Labour.
Dr. R. W. Simpson*	Newcastle-on-Tyne, North	Liberal.
Dr. E. G. Spero*	Stoke Newington	Liberal.
Dr. Thomas Watts†	Manchester, Withington	Conservative.
Dr. J. H. Williams†	Carmarthen, Llanelly	Labour.
Dr. R. McNair Wilson*	Essex, Saffron Walden	Liberal.

Some Personal Records: New Candidates.

Of the new medical candidates, Olaf Gleeson, M.R.C.S. Eng., who is contesting Portsmouth in the Labour interest, is an old Westminster Hospital student who qualified in 1915, and served as a captain in the R.A.M.C.(T.)—George Brown Hillman, M.B.E., L.M.S.S.A., who is Conservative candidate for the Normanton Division of Yorkshire, qualified in 1892, is honorary captain, R.A.M.C., and medical referee to the Ministry of Pensions. As a member of the West Riding County Council Public Health Committee he has devoted much time to improving the present methods of dealing with tuberculosis and in work connected with child welfare.—Alfred George Newell, M.D. Glasg., D.P.H., qualified in 1894, and has occupied important public health appointments abroad, being at one time professor of hygiene at the Lahore Medical College. During the war he was on the staff of the Royal Waterloo Hospital, and he was chairman last year of the Middlesex Division of the British Medical Association.

Candidates for Re-election.

We have on a previous occasion set out the reasons for which many of these are seeking Parliamentary suffrage. Dr. Ethel Bentham will continue to emphasise the importance of housing in relation to health.—Dr. Dunstan, as a medical practitioner working in a poor district and impressed with the close association between the evils of present-day society and the incidence of disease and death, regards it as useless to try to alleviate disease and suffering without at the same time dealing drastically with the underlying economic cause.—Dr. Fremantle aims at reorganising in one great scheme the measures for insuring people against ill-health, unemployment, and old age, and removing any discouragement to thrift. He hopes to see incorporated in this scheme the long-needed reform of the Poor-law.—Mr. Hastings, who is now standing for Reading, is laying special stress on the social programme, most of all on the needs of the coming generation. He has found evidence that unemployment has resulted in deterioration in the physical condition of the children of the unemployed. He holds the view that a well-fed, well-housed, and well-educated democracy can be safely trusted to look after its own destiny.—Dr. Salter is pledged to deal with unemployment and housing, the two greatest social sores of the moment. He derives his politics from his religion and aims at establishing peace and goodwill on earth.—Sir S. Russell-Wells desires to see modifications in the panel system. He will oppose any attempt to place the doctors under the heel of approved societies or to convert the profession into a sweated industry.

Support.

The Parliamentary Elections Committee of the British Medical Association is supporting the candidature of Sir S. Russell-Wells, Dr. Watts, Dr. Hillman, and Dr. Newell. The Committee has also conveyed its best wishes for success in their candidature to the following: Dr. Chapple, Lieut.-Colonel Fremantle, Captain Elliot, and Major Molson. The Federation of Medical and Allied Services is placing its machinery at the disposal of all the medical candidates who were successful last year as well as that of others who desire it.

Medical News.

University of London.—At a meeting of the Senate held on Nov. 21st Mr. W. E. Le Gros Clark was appointed as from Jan. 1st, 1924, to the newly-instituted Readership in Anatomy tenable at St. Bartholomew's Hospital Medical College. The D.Sc. in Embryology was conferred on Miss Margaret Tribe (University and King's Colleges) for a thesis entitled the Development of the Hepatic Venous System and the Postcaval Vein in the Marsupialia. It was resolved that the Physiological Laboratory Library should be kept together as part of the University Library and be developed in connexion therewith as a memorial to the late Prof. A. D. Waller.

At examinations held recently the following candidates were successful:—

Diploma in Psychological Medicine.

With special knowledge of Psychiatry.—Basil W. Brown, Harold E. Brown, Isabel F. King, Thomas Lindsay, and John Wall.

Small-pox in England and Wales.—During the week ended Nov. 17th 44 cases of small-pox were reported to the following sanitary authorities: Derby 15 (Heanor 2, Ripley 1, Blackwell R.D. 12); Durham 1 (Gateshead); Gloucestershire 11 (Gloucester 6, East Dean 5); Kent 1 (Chatham); Notts 13 (Hucknall 8, Basford R.D. 5); Yorks W.R. 3 (Adwick-le-Street).

Old Epsomian Club.—The annual dinner will take place on Dec. 13th, at 7.30 p.m., at the Trocadero Restaurant, when Mr. W. Æ. Mackay (Carr House, 1886–89) will be in the chair. The price of the dinner will be 10*s.* 6*d.* (exclusive of wine), and will be collected at the table. Members intending to be present are requested to send their names to the hon. sec., S. Maynard Smith, 49, Wimpole-street, W. 1, as soon as possible, giving the names of any members near whom they would like to sit. The annual meeting will be held at the restaurant before the dinner, Dr. H. F. Ealand, the retiring President, taking the chair at 6.30 p.m.

Royal Sanitary Institute.—A conference of veterinary officials will be held at 3 p.m. on Dec. 14th, at 90, Buckingham Palace-road, London, S.W., when Alderman W. Phene Neal (late chairman of Cattle Markets Committee, City of London) will open a discussion on Tuberculosis in Cattle and the Desirability of allowing the introduction of Breeding Heifers from Canada if Certified Free from Tuberculosis. The chair will be taken by Dr. Louis C. Parkes (Chairman of Council).

The next Congress of the Institute will be held at Liverpool from July 14th to 19th, 1924, by invitation of the Lord Mayor and City Council.

Prize for Cancer Research.—The committee of the Christie Hospital is offering a prize of £300 for Cancer Research. Candidates must be qualified in medicine or in science cognate to medicine, and must submit evidence of original research work bearing on cancer done and projected, which shall in the opinion of the assessors qualify him for the prize. The object of the prize is to support research work already in progress. The assessors will take into consideration promising work which might fail for want of financial help. The competition is open to research workers of any nationality. Applications must be sent to the chairman of the Medical Board, Christie Hospital, Manchester, on or before Dec. 31st, 1924.

The late Dr. William Gowans.—Dr. Gowans, a well-known South Shields medical practitioner, honorary surgeon to the Ingham Infirmary, and president of the North of England Branch of the British Medical Association, died from septicæmia following a cut thumb while stropping a razor. Qualifying with the L.R.C.P. and L.R.C.S. Edin. in 1868, Dr. Gowans entered on general practice and obtained the F.R.C.S. Edin in 1883. He graduated M.D. at Durham University in 1886. A vice-president of the Northumberland and Durham Medical Society, he was surgeon to H.M.S. *Wellesley* training ship, and at one time was an honorary surgeon and a commanding officer to the old 3rd Durham Artillery Volunteers. He had been a justice of the peace since 1892.

National Health Insurance: Court of Inquiry. The Court of Inquiry to be appointed by the Minister of Health and the Secretary for Scotland, with reference to the amount of the capitation fee to be paid, as from Jan. 1st, 1924, to practitioners serving under the National Health Insurance Scheme will be composed of as follows: Chairman, Mr. T. R. Hughes, K.C. (Chairman of the General Council of the Bar) with Mr. F. C. Goodenough (Chairman of Barclay's Bank) and Sir Josiah Stamp, K.B.E. The last-named was one of the arbitrators appointed by the Government to deal with the question in 1920. The terms of reference to the Committee will be published later.

Mr. Dudley Cox Trott, F.R.C.S. Eng., has been appointed an unofficial member of the Executive Council of the Bermudas or Somers Islands.

Chelsea Clinical Society.—The first meeting of the session took place at St. George's Hospital on Nov. 20th, Dr. G. Crewsdon Thomas, the President, in the chair. In the absence of Sir Sydney Russell-Wells, owing to illness, a discussion on the Treatment of the Failing Heart was opened by Dr. John Parkinson, supported by Dr. C. E. Sundell and Dr. Robert Hutchison. Drs. Gordon Lane, H. A. Ellis, K. Eckenstein, J. D. Rolleston, G. H. Hunt, and the President took part in the discussion.

Aberdeen Medico-Chirurgical Society.—The annual business meeting of this Society was held on Nov. 22nd, when the following office-bearers were appointed:—

President: Dr. George M. Duncan. Vice-President: Dr. Peter Howie. Secretary: Dr. H. Edgar Smith. Recording Secretary: Dr. H. Ross Souper. Assistant Secretary: Dr. Robert Richards. Treasurer: Dr. George Rose. Librarian: Dr. W. Clark Souter. Editor of Transactions: Mr. G. H. Colt. Members of Council: Dr. Alexander Ogston, Dr. James Crombie, Dr. W. Clark Souter, and Dr. William Brown.

Incorporated Vermin Repression Society and College of Pestology.—At the annual dinner of the Society and College held on Nov. 21st, Lord Aberconway recalled the fact that 15 years ago he introduced the first "anti-rats" Bill into the House of Commons. To-day their Society occupied a unique position in the world; they could claim to have originated the scientific instructional film, and their anti-rat film was acknowledged by the Government to be the finest propaganda of its kind. The Society was known by its child the Rats Act, and by its lectures and writings, having been consulted by the Governments of Poland, France, New Zealand, America, Greece, Egypt, and the Gold Coast. Their concern was not only with rats and mice, whose depredations cost the British Isles well over £40,000,000 per annum, but also with vermin generally; through associated societies they had been able to arouse public opinion to the danger underlying the existence of body vermin. The year's balance-sheet told a story of enthusiastic devotion on the part of unpaid officials, and a paucity of funds which starved the usefulness of the Society.

London School of Tropical Medicine: School Dinner.—The annual dinner of the Seamen's Hospital Society, being the London School of Tropical Medicine, took place at the Hotel Victoria, Northumberland-avenue, on Nov. 21st, Sir Ion Hamilton Benn occupying the chair. In proposing "The School," in its twenty-fourth year of existence, the Chairman reminded his hearers of its two great benefactors, Joseph Chamberlain and Patrick Manson, and went on to enumerate the 20 scientific expeditions which the School had arranged. Dr. J. G. Thomson was but lately returned from Rhodesia with a fund of new knowledge regarding blackwater fever, while Dr. and Mrs. P. A. Buxton, with Mr. G. W. Hopkins had just started for Samoa in an endeavour to solve the problem of filariasis. He spoke of the Rockefeller Institute and its newly appointed director, Dr. Andrew Balfour, in which the School might indeed lose some of its autonomy, albeit this really rested with the men who staffed the School. Sir Arthur Clarke proposed "The Guests," among whom were Sir James Allen (High Commissioner for New Zealand), Surgeon Vice-Admiral J. Chambers, Sir William Leishman, Sir Walter Fletcher, and Lord Devonport. He congratulated the last-named on the achievement of having collected by aided effort the remarkable sum of £200,000 for the Seamen's Hospital. The School was, he said, retaining its name within the Rockefeller Institute in honour of the memory of Manson. Sir James Allen, in reply, spoke of the generous help offered to New Zealand by the School and warmly welcomed the Buxton-Hopkins expedition. Dr. J. M. H. Macleod proposed "The Chairman," who briefly replied. The intervals were filled up with an agreeable programme of music provided by Dr. T. Goodey and others.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.—The first general meeting of the session will be held on Dec. 7th, 8.30 P.M., at 11, Chandos-street, London, W., when the presidential address will be given by Lieut.-Colonel L. W. Harrison.

ROYAL NORTHERN GROUP OF HOSPITALS.—A festival dinner was held in the Mansion House on Nov. 21st with the object of raising money to open 70 beds which had been closed owing to the strained financial position of the hospitals. The chair was taken by Earl Beatty, Admiral of the Fleet, who made a strong appeal on behalf of the Royal Northern Group of Hospitals, which, he said, had grown from the humble origin of one bed in a single room in a little side street in North London to its present great efficiency and size, now serving a population of a million. In reply to Earl Beatty's toast of "Success to the Hospital," Lord Northampton (chairman of the hospital) said that while there had been an increase in the cost of hospital services, their income had also increased, thanks largely to the ingenious schemes of their secretary, Mr. Gilbert G. Panter. Still, there was a deficit for the year of about £15,000. The closure of 70 beds was calculated to save this sum, but at the same time it meant that 1000 cases had to go untreated. Expansion, not reduction, was needed in North London. The toast of the Lord Mayor and Corporation was given by Sir Philip Sassoon, supported by the Rev. Basil Bourchier, and acknowledged by the Lord Mayor; and that of the chairman was given by Lord Riddell. During the dinner guests were invited individually to promise contributions towards the hospital funds. The response was liberal, and the secretary was able to announce later in the evening the gratifying total of £11,643. The cost of the dinner had been generously defrayed by Lord Northampton.

THE UNIVERSITY OF EDINBURGH GRADUATES IN LONDON CLUB.—The 200th dinner of the Club, held in the Connaught Rooms on Nov. 23rd, was attended by some 400 members and their guests, the Rt. Hon. the Earl of Balfour in the chair. In proposing the toast of "The Alma Mater and the Edinburgh University Club of London," Lord Balfour said that our great educational institutions had two antitheses to reconcile—namely, general culture and accurate scientific knowledge—and every year this problem became more insistent. "Many will be disposed to admit," he continued, "that it is not merely—not mainly—in the lecture-room that educational gains have been chiefly acquired. Lectures do much, contact with great teachers does more, but most of all, as we look back, do students learn from each other. It is the collision of individual character and interest that makes university training a unique benefit. It is not merely hours spent in hard study that fit a man for the battle that each of us has to fight. Hours of idleness, hours of strenuous enjoyment, the teachings of equals in age, are great educational instruments." Sir James Crichton-Browne (who was chairman in 1889) proposed "Our Guests," to which Sir Humphry Rolleston (President, Royal College of Physicians) and Sir Aston Webb (President, Royal Academy) replied. In giving the health of the chairman, Lord Dunedin spoke of the affection which Lord Balfour inspired in all those with whom he came into contact. The toast was received with musical honours and Lord Balfour, in reply, spoke appreciatively of his friendship with Lord Dunedin.

BRIGHTON WATER-SUPPLY.—The house shortage at Brighton has become so acute that residences of the bungalow type are being erected wholesale on the confines of the town where in normal times and in normal circumstances such habitations would never have been considered. Questions of water-supply and drainage have been more or less left to take care of themselves. So many bungalows have been erected in one particular locality that there is the possibility of their becoming a menace to the water-supply of Brighton. Patcham is one of the important sources of supply and, acting on the advice of the waterworks engineer, the corporation has decided to take immediate steps to acquire all the lands in the neighbourhood of the pumping station whereon houses are now being built, or are likely to be built in the future, which, if erected without regard to proper drainage conditions, might affect the water-supply. Furthermore, the corporation has decided to seek powers to make by-laws by which they may be able to control all works of drainage in connexion with building operations upon lands in the neighbourhood of their pumping stations so as to maintain the absolute purity of the water-supply. Patcham station is for the moment the immediate objective for the powers sought, but these powers will soon be needed, for the same reason, in respect of the five other pumping stations which are scattered over the South Downs. The Brighton corporation's water area covers no fewer than 44½ square miles, with a resident population of upwards of 200,000, a figure greatly increased during the summer months by the vast numbers of holiday visitors.

INFLUENCE OF ENVIRONMENT ON THE LIFE OF BACTERIA.—A course of five lectures on this subject will be given by Dr. F. W. Twort, superintendent of the Brown Institution, in the theatre of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C., on Dec. 11th, 13th, 17th, 18th, and 19th, at 4 P.M. Admission is free without ticket.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of the Metropolitan and Home Counties Maternity and Child Welfare Sub-Group will be held at 1, Upper Montague-street, Russell-square, W.C., on Dec. 7th, at 5.30 P.M., when Dr. J. W. Carr will read a paper on Signs and Symptoms of Tuberculosis of the Respiratory System in Children under Five. The meeting is open to all members of the medical profession.

COMMISSIONS IN THE R.A.M.C.—An examination for not fewer than 40 commissions in the Royal Army Medical Corps will be held on Jan. 30th next. Applications should be made to the Secretary of the War Office not later than Jan. 20th, and the presence of candidates will be required in London from Jan. 28th. Meantime those intending to compete can obtain a full statement of the duties and emoluments of the service on making written application to the Secretary, War Office, Whitehall, London, S.W. 1.

MEDICAL BENEFIT FINANCE.—In an official statement issued on Nov. 24th the Minister of Health says: Many approved societies' representatives maintain that no greater sum than 7*s.* 3*d.* per member can be taken from the funds of societies without curtailing either the ordinary cash benefits or the additional cash benefits which are already provided for their members. The Government actuary has advised that societies in general can find anything up to 8*s.* 6*d.* from their funds for the next five years without endangering the continuance of existing benefits, including additional benefits already in operation.

ROYAL DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff, and past and present students of the hospital, was held in the Trocadero Restaurant, on Saturday, Nov. 24th. The company numbered about 200, Mr. G. Northcroft, L.D.S., presiding. The Chairman, in the course of his toast to "The Past and Present Students of the Royal Dental Hospital and Dental School," announced that playing fields had now been acquired for the use of the school. In replying, the Dean, Mr. H. Stobie, L.D.S., referred to the appointment of a lecturer in radiology, and paid an appreciative tribute to his colleague, Mr. W. H. Dolamore, L.D.S., who was retiring from the teaching staff. He spoke of Mr. Dolamore as one of the finest teachers the school had ever had, a man whose initiative and determination in the face of opposition had achieved much in the interests of all dental students.

THE LATE DR. A. J. STILES.—The death occurred on Nov. 21st, at Spalding, Lincolnshire, of Dr. Arthur Jalland Stiles, in his sixty-fourth year. He graduated M.B., C.M. with distinction at Edinburgh University in 1883, where, three years later, he obtained his M.D. with commendation. In 1883 he was also admitted L.M.R.C.P.I., and the following year M.R.C.S. Eng. and L.M. Rotunda Hospital, Dublin. Dr. Stiles was one of the best known practitioners in Lincolnshire and one of the most active public men in Spalding. He was a magistrate for the Elloe division of Lincolnshire, a governor of Spalding Grammar School, a trustee of Spalding Hospital, and was associated with many other public bodies. Dr. Stiles was a brother of Sir Harold Stiles, of Edinburgh, and both his father and his grandfather practised in South Lincolnshire.

AUGUSTUS AND ALICE WALLER MEMORIAL.—A representative meeting held at the Royal Society of Medicine on June 1st last, under the chairmanship of Sir Edward Sharpey Schafer, resolved to establish a memorial to the late Prof. Augustus D. Waller, F.R.S., and Mrs. Waller, in recognition of their life-long devotion to physiological investigation. The memorial is to take the form of a fund to be used for the encouragement of scientific research. Its administration is to be entrusted to the Council of the London (R.F.H.) School of Medicine for Women. Since this meeting it has been suggested that an additional memorial might suitably be established at St. Mary's Hospital Medical School in the form of a research room, to be called the Waller Research Laboratory, in connexion with the physiological department. An influential committee has been formed to give effect to the suggestions, and it is hoped that a sum of £5000 may be raised; £1300 have already been subscribed. Subscriptions should be sent to the Hon. Treasurer, Prof. J. Mellanby, St. Thomas's Hospital Medical School, London S.E. 1, and if it is desired that donations, or any part of them, should be allocated to the St. Mary's Memorial, this should be expressed.

LONDON JEWISH HOSPITAL.—A festival dinner was held in the Connaught Rooms on Nov. 26th, Sir Humphry Rolleston in the chair. In proposing the toast of the London Jewish Hospital, the chairman emphasised the need of such a hospital in London, where there were a quarter of a million Jews. The hospital provided 50 beds and met a great need not only to the Jews, for of 52,000 out-patient attendances in 1922 about 40 per cent. were Gentiles. "To the excellence of the staff, its accommodation, X ray installation, operating theatre," he said, "I can testify with confidence, and more valuable than a personal testimonial is the practical proof of recognition by King Edward VII. Hospital, the Saturday and the Sunday Funds for financial help, and by its acceptance as a complete training school for nurses by the General Nursing Council for England and Wales. The hospital is not nearly finished, but there is a debt of already £10,000. Not only is the original plan not yet completed, but extension of the out-patient department is becoming urgent." The health of the Guests was proposed by the Chief Rabbi, the Very Rev. Dr. J. H. Herz, and Sir John Bland-Sutton replied to the toast of the Medical Profession.

THE LATE MR. G. T. BROOKSBANK JAMES.—George Thomas Brooksbank James, who died at Chichester on Nov. 15th at the age of 56, received his medical education at Westminster Hospital, where he gained the entrance scholarship and was admitted L.R.C.P. Lond. and M.R.C.S. Eng. in 1890. He held the resident posts of house surgeon and house physician at Westminster Hospital, and then turned his attention to ophthalmology. He obtained the F.R.C.S. in 1896, and in 1899 was appointed honorary assistant surgeon to the Royal Eye Hospital, Southwark, becoming honorary surgeon five years later. In 1903 he was appointed assistant ophthalmic surgeon to Westminster Hospital, becoming full surgeon in 1914. He spent part of every week at Eastbourne, where he was honorary ophthalmic surgeon to the Princess Alice Hospital. An as ophthalmologist he was a keen observer and a neat and precise operator. Systematic teaching did not much interest him, but when he had occasion to give a post-graduate lecture, it was a model of careful preparation and exhaustive treatment of the subject. He was especially interested in binocular vision and squint, a subject upon which he made many ingenious and original observations, some of which were reported in THE LANCET (1909) and in the Transactions of the Ophthalmological Society (1909). He spent much time and energy in devising new apparatus, but his modesty prevented his exhibiting his ideas to the profession or even to his immediate colleagues. Another subject in which he was keenly interested was that of glaucoma, and he described in 1912 a new method of operating for this, a method which he employed with great success. On those who worked with him he left the impression of an unusually original and versatile thinker.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.

THURSDAY, Dec. 6th.—At 4.30 P.M.

Papers to be read.—E. G. T. Liddell and Sir Charles Sherrington, Pres., R.S.: Recruitment Type of Reflexes. G. S. Carter: The Structure and Movements of the Latero-Frontal Cilia of the Gills of Mytilus. (Communicated by Prof. J. S. Gardiner.)

Papers to be read in title only.—V. B. Wigglesworth and C. E. Woodrow: The Relation between the Phosphate in Blood and Urine. (Communicated by Prof. F. G. Hopkins.) J. B. S. Haldane, V. B. Wigglesworth, and C. E. Woodrow: The Effect of Reaction Changes on Human Inorganic Metabolism. (Communicated by Prof. F. G. Hopkins.) J. B. S. Haldane, V. B. Wigglesworth, and C. E. Woodrow: The Effect of Reaction Changes on Human Carbohydrate and Oxygen Metabolism. (Communicated by Prof. F. G. Hopkins.) J. A. Campbell: Concerning the Influence of Atmospheric Conditions upon the Pulse-rate and "Oxygen-Debt" after Running. (Communicated by Prof. L. Hill.) J. Gray: The Mechanism of Ciliary Movement, IV. The Relation of Ciliary Activity of Oxygen Consumption. (Communicated by Prof. J. S. Gardiner.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Dec. 3rd.

OCCASIONAL LECTURE: at 5.30 P.M.

Dr. Strandberg (Copenhagen): Treatment of Tuberculosis of the Nose and Throat by Finsen Light Baths; results (with epidiascopic illustrations).

Members of the Sections of Electro-therapeutics, Laryngology, and Medicine are specially invited to attend this lecture.

TROPICAL DISEASES AND PARASITOLOGY: at 8.30 P.M.

Communication:

Dr. Bamforth: Note on a Small Outbreak of Dysentery associated with an unusual bacillus.

Discussion:

On Sprue and Cœliac Disease. To be opened by Sir Leonard Rogers. Dr. Aldo Castellani, Dr. Reginald Miller, Dr. H. H. Scott, Dr. S. Arthur Powell, Lieut.-Colonel W. P. MacArthur, and others will speak.

Members of other Sections, and especially of the Section for the Study of Disease in Children, are cordially invited to attend.

Tuesday, Dec. 4th.

ORTHOPÆDICS: at 5.30 P.M. (Cases at 5 P.M.)

Discussion:

On Myositis Ossificans Traumatica. To be opened by Sir George Makins.

Fellows and Members are invited to show patients, radiographs, or specimens illustrating the subject under discussion.

PATHOLOGY: at 8.30 P.M. in the Pathological Dept., University College Hospital Medical School, Gower-street, W.C. 1.

Communications, &c.:

Dr. G. W. Goodhart: Achlorhydria and Achylia Gastrica.
Dr. Cecil Price-Jones: Contact Hæmolysis.
Dr. A. M. H. Gray: Chalky Tumours of Skin.
Mr. R. Grant: Bicuspid Aortic Valves and Subacute Infective Endocarditis.
Mr. V. R. Khanolkar: Non-specific Training of Antibody Production.
Dr. J. W. McNee: Experiments on Bile-pigment Formation.
Mr. W. G. Barnard: Pathological specimens.

Wednesday, Dec. 5th.

SURGERY: at 5.30 P.M. (Cases at 5 P.M.)

Pathological and Clinical Meeting:

Members are invited to bring patients and pathological specimens, and to send particulars of these to the Hon. Secretary (Mr. H. W. Carson, 111, Harley-street, W.), as soon as possible, but in any case not later than Dec. 3rd.

Patients should be in attendance by 5 P.M., and it would greatly facilitate arrangements if pathological specimens were accompanied by short descriptive labels.

Thursday, Dec. 6th.

OCCASIONAL LECTURE: at 5.30 P.M.

Sir Jagadis Bose: Assimilation and Circulation in Plant (with demonstration of apparatus).

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.

Specimens:

Mr. T. G. Stevens: (1) Endothelioma of Bartholin's Gland; (2) a Very Early Stage of a Papilliferous Growth in an Ovarian Cyst.

Mr. J. Bright Banister: (1) Sarcoma of the Fallopian Tube; (2) Carcinoma of the Fallopian Tube; (3) Ruptured Cæsarean Section Scar.

Short Communication:

Dr. Victor Lack: A case of Cyst Development in an Ovarian Graft.

Papers:

Dr. T. I. Candy: Radiography of the Fœtus in Utero.
Dr. Geoffrey Fildes: Radiography of the Fœtus in Utero.

Demonstration:

Prof. Louise McIlroy: Diagnosis of Pregnancy by X Rays

Friday, Dec. 7th.

LARYNGOLOGY: at 5 P.M. (Cases at 4 P.M.)

Cases and specimens will be shown by Dr. Russ Wood, Mr. Scott Ridout, Mr. Peters, Dr. Dan McKenzie, Dr. Cathcart, Sir James Dundas-Grant, Mr. T. B. Layton, and others.

LARYNGOLOGY: at 8.30 P.M.
ANÆSTHETICS: ,,
ODONTOLOGY: ,,
OPHTHALMOLOGY: ,,
OTOLOGY: ,,
SURGERY: ,,

Joint Discussion:

On the Comparative Value of Cocaine Substitutes. To be opened by Dr. P. Watson-Williams. Followed by Mr Foster Moore (Ophthalmology), Mr. F. N. Doubleday (Odontology), Mr. F. S. Rood (Anæsthetics), Sir William Milligan (Otology), and others.

Saturday, Dec. 8th.

OTOLOGY: at 10 A.M.

Cases and Specimens:

Mr. A. H. Cheatle: Three cases of Injury to the Ear caused by Spirit Injection for Neuralgia.

Sir James Dundas-Grant: Two (old) cases of Radica Mastoid Operation without Plastic.

Cases will also be shown by Dr. T. B. Jobson, Dr. A. R Friel, and others.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY, Dec. 5th.—8 P.M., Mr. Arthur William Hill The Work of the Royal Botanic Gardens, Kew.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Dec. 3rd, to THURSDAY, Dec. 6th.—Lectures a the Hampstead General Hospital, Royal Westminste Ophthalmic Hospital, and the Western Genera Dispensary (Children's Clinic).

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday, Dec. 3rd.—10 A.M., Mr. Maingot: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 2.30 P.M., Mr. Addison: Surgical Wards.

Tuesday.—11 A.M., Dr. McDougal: Electrical Dept. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Dr. Pritchard: Medical Wards.

Wednesday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

Thursday.—11 A.M., Mr. Simson: Gynæcological Demonstration. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

Friday.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Mr. Endean: Venereal Diseases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

Saturday.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

UNIVERSITY COLLEGE HOSPITAL.

Wednesday, Dec. 5th.—5 P.M., Dr. Charles Singer: Representation of Disease in Art.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, Dec. 6th.—4 P.M., Dr. Pearson: Chronic Infections of the Lung.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

Thursday, Dec. 6th.—5 P.M., Mr. L. C. Rivett: Hydramnios.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

Tuesday, Dec. 4th.—5 P.M., Dr. A. Whitfield: Fungus Infections.

Thursday.—5 P.M., Dr. W. K. Sibley: Acne.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

Wednesday, Dec. 5th.—4 P.M., Dr. A. H. Bygott: Problems of Death Certification and Registration.

THE PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, Oxford-street, W.

Eight Lectures on the Mind and What We Ought to Know About It, at Hamilton House, Mabledon-place, W.C.

Wednesday, Dec. 5th.—6 P.M., Sixth Lecture, Sir Frederick Mott: Mind and Body.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES.

Monday, Dec. 3rd.—(At the Children's Hospital.) Mr. W. A. Thompson: Appendicitis and Intussusception in Children.

Tuesday.—(At the Southern Hospital.) Mr. O. H. Williams: Diagnosis of Chronic Pain in the Abdomen.

Wednesday.—(At the Northern Hospital.) Mr. Rawlinson: Genito-urinary Cases.

Thursday.—(At the Stanley Hospital.) Mr. J. P. Morrison: Surgical Tuberculosis in Adults.

Friday.—(At the Royal Infirmary.) Dr. MacKenna: Eczema and its Treatment.

MANCHESTER ROYAL INFIRMARY.

Tuesday, Dec. 4th.—4.15 P.M., Mr. J. Morley: Acute Obstructive Cholecystitis.

Friday.—4.15 P.M., Prof. J. S. B. Stopford: The Sensory Pathway.

ANCOATS HOSPITAL.

(Special Course on Surgical Tuberculosis.)

Thursday, Dec. 6th.—4.30 P.M., Mr. F. H. Diggle: Otolaryngeal Tuberculosis.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES.

Tuesday, Dec. 4th.—(At the Royal Infirmary.) 3.30 P.M., Mr. Cuff: Clinical Cases.

Friday.—(At the Royal Infirmary.) 3.30 P.M., Dr. Barnes: The Early Diagnosis of Gall-stones.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

Friday, Dec. 7th.—(At Boscombe.) Dr. C. E. K. Herapath: Bradycardia and Tachycardia.

Appointments.

Gaye, A. W., M.B., B.Ch. Camb. & Manch., has been appointed Assistant Medical Officer of Health for Ipswich.

Roth, P. Bernard, F.R.C.S. Eng., Orthopædic Surgeon to the London Homœopathic Hospital.

Queen Charlotte's Lying-in Hospital: **Hall, N. B.**, M.B., B.S. Adelaide, Resident Medical Officer; **Page, Hilda**, M.R.C.S., L.R.C.P. Lond., and **Ramsden, W. M.**, M.B., B.S., M.R.C.S., L.R.C.P. Lond., Assistant Resident Medical Officers.

Vacancies.

For further information refer to the advertisement columns.

Birmingham and Midland Eye Hospital, Church-street.—Res. S.O. £150. Also Second H.S. £110.

Birmingham City Hospital for Infectious Diseases, Little Bromwich—Sen. Asst. M.O. £350.

Brighton County Borough Mental Hospital, Hayward's Heath.—First Asst. M.O. £700.

Camberwell Infirmary.—Asst. Med. Supt. £500.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.

Colonial Service, British Guiana.—Three Asst. Govt. M.O.'s. £500.

Coventry and Warwickshire Hospital.—Hon. Pathologist. £200.

Darlington Union.—M.O. and Public Vaccinator. £604 14*s.* 2*d.*

Derby, Royal Derby and Derbyshire Nursing and Sanitary Association.—Hon. Obstet. P.

Eastbourne, Royal Eye Hospital.—Hon. Anæsthetist.

East London Hospital for Children, &c., Shadwell, E.—Morning Cas. O. £120.

Edinburgh Royal Infirmary.—Supt. £700.

Federated Malay States Hospitals.—Radiologist. £840.

Folkestone, Royal Victoria Hospital.—Res. M.O. £150.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.P., H.S., Cas. M.O. and Cas. S.O. Each £100.

Hospital for Women, Soho-square, W.—Res. M.O. £100.

Huddersfield, Bradley Wood Sanatorium, &c.—Res. M.O. £500.

Johannesburg, South African Institute for Medical Research.—Asst. Pathologist. £800.

Kensington, Fulham, and Chelsea Hospital, Earl's Court, S.W.—Hon. Anæsth.

Leeds Public Dispensary.—Hon. Radiologist. Also Hon. Dental Surgeon.

Lincoln County Hospital.—Sen. H.S. £250.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. £150.

Manchester Royal Infirmary.—Sen. Med. Reg. £150. Also Asst. M.O. £35.

Middlesex Hospital, W.—M.O. Electrotherapy Dept. £300. Sen. Asst. Radiologist. £500. Two Asst. Radiologists. Each £100.

Middlesex Hospital and Medical School, W.—Eight Registrarships. Each £300.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. P. Also Res. M.O. £200.

Oxford, Radcliffe Infirmary and County Hospital.—Res. Accoucheur. £120.

Plymouth, South Devon and East Cornwall Hospital.—H.S. £125.

Preston Royal Infirmary.—H.S. £200.

Prince of Wales's General Hospital, Tottenham N.—H.S. £150 Clin. Assts.

Queen Mary's Hospital for the East End, Stratford, E.—Res. M.O. and Res. Obstet. S.

Royal Free Hospital, Gray's Inn-road, W.C.—Asst. P.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Hon. P.

St. Peter's Hospital, Henrietta-street, Covent Garden, W.C.—Secretary. £400. Also Clin. Assts.

Salford Royal Hospital.—Anæsthetist. £1 1*s.* per session.

Union of South Africa Govt.—Asst. P.'s. £460.

University College Hospital, Gower-street, W.C.—Tuberculosis O. £300.

Western Dispensary, 38, Rochester-row, Westminster, S.W.—Resident. £100.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S., and Res. Cas. O. Each £100.

Whalley, near Blackburn, Claderstones Certified Institution for Mental Defectives.—Asst. M.O. £432.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Waltham Abbey (Essex) and Dulverton (Somerset).

Births, Marriages, and Deaths.

BIRTHS.

Baron.—On Nov. 19th, at Golders Green, N.W., the wife of Dr. R. W. Baron, of a daughter.

Kane.—On Nov. 23rd, the wife of M. Kane, M.C., M.B., B.S., of Gwanda, S. Rhodesia, of a daughter.

McMillan.—On Nov. 13th, at Dudley-road Hospital, Birmingham, the wife of Kenneth McMillan, F.R.C.S., of a son.

MARRIAGES.

Galbraith—Gledhill.—On Nov. 22nd, at the Congregational Church, Bromley, Samuel Nicol Galbraith, M.B., D.P.H., to May, only daughter of the late James Gledhill and of Mrs. Gledhill, "St. Andrew's," Plaistow-lane, Bromley, Kent.

Nichols—Mason.—On Nov. 19th, at Seaview, Isle of Wight, Henry Wilfrid Lee Nichols, M.R.C.S., L.R.C.P., to Margaret Dorothy Mason, M.R.C.S., L.R.C.P., elder daughter of Mr. and Mrs. Charles Mason, of Wepener, Seaview.

DEATHS.

Ashton.—On Nov. 23rd, at Rue Libergier, Rheims, Charles Ernest Ashton, M.R.C.S. Eng.

Elliott.—On Nov. 22nd, in King's College Hospital, after an operation, C. N. Elliott, M.B., J.P., of Oundle, Northants, aged 75.

Roe.—On Nov. 13th, at The Moorings, Gorran Haven, Cornwall, Montagu Walter Roe, M.R.C.S., L.S.A., aged 62.

Stiles.—On Nov. 21st, at The Terrace, Spalding, Lincs, Arthur Jalland Stiles, M.D., J.P., aged 63 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE POSITION OF PHYSIOLOGY IN SCIENCE AND MEDICINE.[1]

By R. J. S. McDowall, D.Sc., M.B., M.R.C.P.Edin.,
PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, UNIVERSITY OF LONDON.

Medicine emerged from the shadow of the Dark Ages in a perilous state, having been held together for 1400 years only by the erroneous theories of Galen, and ruled by blind speculation and dogmatism. With the Renaissance came the rebirth of medicine, particularly of anatomy. Modern physiology owes its beginnings and inspiration to the great anatomists of the sixteenth century; Padua, under the guidance of Vesalius, rose to be the greatest medical school in Europe, and practical observation became the keynote of the new medicine.

Foundations of Modern Physiology.

William Harvey, whose discovery of the circulation was published in 1628, was a graduate of Cambridge who subsequently studied at Padua, whence no doubt he derived much inspiration. Harvey's work marks the dawn of experimental method, and must always remain a masterpiece of physiological reasoning. The tempting subject of the function of the human body naturally attracted physicists, full of the discoveries of Galileo and his contemporaries. Mathematical laws were rigidly applied to physiological problems; for example, Borelli knew that the heart was about the size of the muscles which move the jaw, and by finding the weight which a man could support from his lower jaw he calculated the force of the heart, which he found to be 135,000 lb. Another member of the school, on a dynamical basis, calculated the same force to be 16 oz. Mathematical calculation replaced the necessity for practical experiment and careful observation, and if a warning is necessary for the future, it may be remembered that Borelli, the greatest of the school, died in poverty. For a period physics and mathematics ran riot in physiology, but left nothing of much permanent value, although we know that later these subjects, combined with accurate observation of biological phenomena, have been of enormous value to physiological science.

The chemists, too, were attracted, with more enduring success. The great outcome of the experimental method of Harvey was the clearing of the physiology of the respiration which up to the time of Lavoisier was entirely the work of British scientists. This period is important in the history of chemistry as well as in that of physiology, as by the discoveries of this time chemistry was emancipated from alchemy. The chemists were not perhaps interested in physiology, but they were engaged in what Sir Clifford Allbutt calls the "pathetic quest after oxygen"; having found the latter and the other fundamental gases they retired from the physiological world, no doubt to study the great discoveries in their own subject.

While Harvey's observations were extended and the capillaries discovered, men began to take an interest in the physiology and minute structure of the digestive tract. These advances were for the most part the result of the discovery of the microscope, and we have at this stage the beginnings of histology. We read, too, of the heroic Spallanzani swallowing sponges tied to pieces of string and pulling them up again that he might investigate the nature of the gastric juice. Since the time of Harvey there has been a steady progress in physiology. With a few exceptions, of which the greatest is perhaps the first recording of blood pressure by Stephen Hales, the advances were made on the continent.

British Physiology.

British physiology is only about 100 years old. In the first instance, the anatomists held the field, and great anatomical schools existed in Edinburgh, Cambridge, and London. The anatomists, who were the only physiologists and the only comparative anatomists, soon realised that the subject was becoming too large for them, and set about founding collateral schools of physiology. One of the earliest chairs in physiology was founded in Edinburgh, and from 1847 was held by Hughes Bennett, in whose memory part of the present physiological laboratory was built. The chair was not, however, a full-time one, and was known as the Institutes of Medicine, a striking sidelight on how important physiology was considered. Bennett was succeeded in 1875 by his pupil Rutherford, who, it is interesting to note, was for a period professor of physiology in this College. From the Edinburgh anatomical school there came to University College, London, in 1836 William Sharpey. He was nominally professor of general anatomy, but worked largely at histology, and soon attracted Michael Foster and Burdon-Sanderson to his laboratory. Foster subsequently, on the recommendation of Huxley, went to Cambridge, and Burdon-Sanderson to Oxford, the latter being succeeded at University College by Schafer, who was also a pupil of Sharpey. As in 1899 Schafer went to Edinburgh to succeed Rutherford, the original Edinburgh school is now only represented by the Glasgow school of physiology. With the latter exception all British physiologists are the direct or indirect descendants of Sharpey and his illustrious pupils.

Since his time the science has advanced with great rapidity, but its record is one of personal toil and hardship. It has been said that all science has progressed by men neglecting what they were paid to do—namely, to teach. It would perhaps be more generous to say that it has progressed as the result of the sacrifice of the spare time of those engaged in it. Physiology has had no more devoted disciple and apostle than my illustrious predecessor Prof. W. D. Halliburton, who in the latter part of last century saw what a future there was for chemistry in physiology, and along with Gamgee and Sheridan Lee, must be considered the founder of British biochemistry. His book, the first of its kind in this country, rescued from chaos the subject to which he has devoted his life. He also wrote a text-book on physiology for students, of which for thirty years a new edition has been required on an average of less than every two years. In 1916 he undertook, at first single-handed, the editorship of "Physiological Abstracts," a monumental work now carried on by Sir William Bayliss and four assistants, and now so important that its taking over by the Medical Research Council is, I believe, being considered. Add to a consideration of his literary work the fact that Halliburton was professor of physiology in this College and in the University, and we have not far to seek for the cause of his premature retirement. We are pleased to think that he can once more be amongst us, and it is our best hope that he will long continue his association with the subject and the College in which he has earned the love and gratitude of his fellow-workers.

Physiology as a Separate Subject.

As a science, physiology makes generous use of the cognate sciences chemistry, physics, mathematics, zoology, and botany. It is impossible to study physiology without having some knowledge of these subjects; physiology to-day is a place of exchange, almost too large to be called a subject. The designation professor of physiology has now very little meaning. For the purpose of the M.B. examination the subject is still divided into histology, experimental physiology, and chemical physiology, but in some schools histology comes under the professor of anatomy, as is customary on the Continent, while chemical physiology is taught by a professor of biochemistry. Chairs of physiology are no longer restricted to those having a medical qualification and the advent of the non-medical physiologist, of which there are now four holding chairs, marks a distinct stage in the development of the subject.

Development of Biochemistry.

As physiology attracted men with special training in chemistry, and as the subject developed, these men found it increasingly harder to keep in touch with those parts of the subject which were not obviously chemical. At first known as chemical physiologists, they are now designated under the more general term biochemists. This separation has led not only to the development of the chemical aspects of physiology, but also to increased study of the nature of the substances found in living organisms from the point of view of pure chemistry. For example, a physiologist is extremely interested in the relationship of adrenalin and urea to the functions of the body; but the average biochemist is just as much, if not more, interested in the artificial building-up and chemical formulæ of these substances. In other words, the biochemist is as closely allied to the organic chemist as he is to the physiologist. I have heard it said that modern biochemists are organic chemists who make a living by teaching physiology; this statement is perhaps a little far-fetched, for the biochemist has now developed an intermediate science of his own, with societies, journals, and an entity increasingly distinct. Young men are now taking up a career of biochemistry quite apart from organic chemistry or physiology. Such subdivision is the inevitable result of the rapid growth of the subject, and whether there will be a similar growth on the physical side is a matter of conjecture. There are, however certain indications of a coming advance from the direction of zoology and botany, in both of which there is a vast wealth of uninvestigated physiology.

---

[1] An extract from the inaugural address delivered at King's College, Oct. 4th, 1923.

Application of Physiology.

But physiology is not a borrower only: it brings new knowledge into the older sciences. The string galvanometer, galvanic electricity, and *beta*-oxidation of fatty acids are examples. The science of physiology pays no heed to its application, nor is it right that it should if real progress is to be made. We must experiment in the cause of knowledge. Many discoveries made in the first instance in the cause of science have subsequently been of enormous benefit to mankind. Who would have thought that the discoveries of Pasteur would have led to the work of Lister? Who would have thought that the Hertzian waves had anything to do with wireless telegraphy? Take also our knowledge of sugar: all sciences have combined in adding to our knowledge of its relation to the animal and vegetable worlds. A vast amount of information has accumulated, but the pure physiologist does not concern himself with whether it is going to be applied to the cure of diabetes or the growing of sugar beet. What was practically insulin was discovered many years ago by Zuelzer, and it appears likely that his experiments failed because he over-dosed his animals. Meantime our knowledge of sugars had greatly increased from the purely scientific aspect; when insulin was again discovered by Banting it was as if a light had been applied to a mass of inflammable material, and all the accumulated knowledge could be applied in an incredibly short space of time for the benefit of mankind. Without the purely scientific advances this application would not have been possible. One is reminded of Spratt, who, when defending the Royal Society for supporting experiments in the cause of mere knowledge, said: "If they are to persist in contemning all experiments excepting those which bring with them immediate gain, they might as well cavil at the providence of God that He has not made all the seasons to be times of mowing, reaping, and harvest."

Physiology and Medicine.

Physiology has a special relation to medicine; we may call physiology the study of the functions of living organs and tissues, while medicine is concerned with the restoration of function which has become abnormal. The physician should therefore know the functions of the various tissues, and the factors on which those functions depend. There was a time when Voltaire said, perhaps with some reason, that doctors were men who poured medicine of which they knew little into bodies of which they knew less; that day is rapidly passing, and the scientific knowledge of the clinician is now as important as his bedside manner. In other words, the art of medicine is being replaced by the science of medicine.

In recent years physiology has been increasingly prominent in medicine. Some of the greatest advances in the treatment of disease have come from physiology—e.g., insulin, thyroid, heart, and kidney therapy. Further, the limitations of physiology are the limits of scientific medicine. Our ignorance of certain diseases, such as nervous diseases or chronic joint conditions, is largely due to our ignorance of the physiology of the parts concerned. The same applies to our knowledge of cancer. As Sir William Bayliss has pointed out, the greatest obstacle is our ignorance of the physiology of the simple cell and cell growth. Physiological literature has become immensely valuable to medicine. Physiology also brings into medicine the methods of science, and these methods are of the utmost value in medical research. The medical student often wonders why he has to learn about old experiments—the medical student lives in constant dread of being over-educated. It is good that he should know how well his predecessors have laboured in his interest, but it is also well that he should know the methods of investigation and to weigh the evidence which results from such investigations that in due course he may apply his knowledge to disease. In this physiology is of enormous value educationally, as the whole subject is made up of methods of investigation and of the results which can be made from the results.

Present Position of Physiology.

To-day physiology has a place of importance it never has had before. The General Medical Council demands more physiology for medical students; the subject is placed on a level with the older pure sciences, and the Royal Society has for the first time a president who is a pure physiologist. But it must not be forgotten that physiology owes its origin to medicine, and especially to anatomy, being taught until comparatively recently by men whose chief interest was really medicine. Medicine has made progress in the subject possible, for the most part providing laboratories and the equipment, and also the means of livelihood for physiologists. There is an increasing tendency for students to take physiology as a science subject, but over 90 per cent. of students who take physiology are still preparing for a medical qualification. Perhaps the words of the late A. D. Waller of this University best sum up the position: "Physiology must be studied for its own sake, but the physiologist whose immediate motive is *the want to know* may not deny his debt of service to the community of which he forms a part and whose services he enjoys. And the channel through which he can repay some part of that debt lies first of all in the service he may be able to render to the practice of medicine—to the knowledge and power of the physician, whose immediate motive is *the want to help.*"

The Future of Physiology.

Now we may glance for a moment into the future. It is indeed a difficult problem. The subject is assuming unmanageable proportions. Expansion by medical men and chemists is well begun, physicists have arrived, botanists and zoologists are at the gate. Broadly speaking, botanists have come to the end of their descriptive, systematic, and histological stage, and the majority are now turning their attention to the physiology of the plant. In zoology, too, there has been an increasing tendency to study the living animal; the older zoologists wonder what is going to become of their subject, so many of the younger men are going over to the physiological side.

There seems to be but one solution—namely, the establishment of a definite subject known as general physiology to include all those who are at present studying the sciences of physiology and biochemistry, together with zoological and botanical physiologists. There is a whole field practically unexplored in the physiology of the lower vertebrates and the invertebrates. The study of homologous organs will throw an enormous amount of light on the physiology of the higher animals. General physiology will be a subject of pure science, included in the preliminary scientific studies of the medical student. It will, I believe, be necessary to teach more principles, with logical reasoning not so over-burdened with detail as to obscure those principles.

There will be a special or applied physiology in which the student will be taken further with special regard to application. Agriculturists will be taught by those who are conversant with the problems of agriculture, medical students by those who know medicine. But the teacher must be a physiologist first, and an applied physiologist later; a knowledge of the fundamental subject is essential. In one University at least in America such a plan has actually been adopted and two well-known physiologists, G. N. Stewart and C. J. Wiggers, have been associated with each other; in this country small courses in applied or human physiology have been instituted to augment scientific physiology.

The ideal is, of course, that the student should leave physiology knowing, so far as modern knowledge permits, what is a normal man. This, of course, means close coöperation with the hospitals. It seems to me that those responsible for the training at hospitals during the first three or even six months should be in direct contact with the physiology departments, if not themselves the applied physiologists. No man would ever think of becoming a surgeon without having a special training in anatomy; physiology bears the same relation to medicine that anatomy does to surgery. The surgeons go so far as to insist that prospective Fellows of the Royal College of Surgeons pass not only a special examination in anatomy, but also one in physiology. I feel sure that if it became fashionable for a man to do post-graduate physiology before going into academic medicine, there would be not only an impetus given to physiology, but also a marked advance in scientific medicine. The physician of the future will, I am persuaded, require a special training in physiology before proceeding to pathology and medicine just as the surgeon requires anatomy. Some other method may be found, but undoubtedly this is the problem of the immediate future in physiology and medicine. Some of you may not agree with what I have said; if so, let us not forget the words of Hippocrates: "Art is long, life is short, experience is fallacious, judgment difficult."

MIDWIFERY TEACHING AND PRACTICE IN INDIA:

ELIMINATION OF THE INDIGENOUS MIDWIFE.

THE efforts being made to improve the condition of midwifery teaching and practice in India are slow to bear fruit, but some progress is being made. In 1921 Sir Norman Walker, who was deputed by the General Medical Council of Britain to visit the Medical College of India and investigate as to the teaching in midwifery, made the following remarks after visiting the Medical College and Hospital, Lucknow: "In every respect, save that of midwifery, it seems to me an admirable institution. Its hospitals, its laboratories and its lecture rooms are all very well equipped, but the 'custom of the country' in respect of midwifery is the same as at Lahore, and there is no early prospect of change." This defect in the teaching of midwifery is now being met (according to the Triennial Report[1] of Civil Hospitals and Dispensaries of the United Provinces for the years 1920, 1921, and 1922, just issued by Colonel A. W. R. Cochrane) by deputation of students to the Madras schools. The College admitted 132 students during the triennium as against 90 in the previous three years; all but 11 were residents of these provinces. According to Colonel Cochrane, who is Inspector-General of Civil Hospitals in the United Provinces, the efforts to improve indigenous dhais financed by the Victoria Memorial Scholarship Fund (Rs.6430 per annum) and by Government (Rs.10,000 per annum) has met with but little success, and it has become recognised that, without relinquishing the efforts to bring about improvement, maternity and child welfare will be better served by the training of women of the non-indigenous class as dhais. These will gradually replace the indigenous women and in the meanwhile force her to improve her methods through the results of competition. Further, it is held to be wiser to concentrate all efforts for improvement at four centres and endeavour to secure real results to serve as an object-lesson of what is possible. The death-rate of children under one year, up to 40 per cent. in some places, is, as Colonel Cochrane observes, an appalling figure.

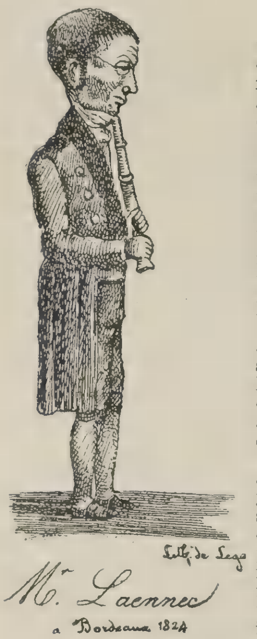
LAËNNEC IN 1824.



The caricature of Laënnec here reproduced is taken from the pages of the special number of the fortnightly *Journal de Bordeaux et du Sud-Ouest*, published on Sept. 20th on the occasion of the Seventeenth Congress of Medicine held at Bordeaux. It is recalled that the welcome given to the invention of the stethoscope in 1816 was at first no more cordial at Bordeaux than at Paris. In 1824, however, a wealthy Spaniard living near Bordeaux summoned Laënnec (the consultation fee being fixed beforehand at 1000 pistoles, or about 10,000 francs), and the latter took advantage of his visit to demonstrate to the Bordelais physicians his method of auscultation. The caricature, apparently the work of a medical student, was drawn upon one of these occasions, and shows "Laënnec en redingote trop large avec une grosse tête sur des jambes grêles, tenir son stéthoscope comme un joueur de clarinette. La charge est d'autant plus de circonstance que le génial médecin était, on le sait, bon musicien et jouait de la flûte." The *Journal de Bordeaux*, it is interesting to note, will celebrate its centenary in 1929.

THE IMMOBILITY OF THE PLANT-BODY.

At a recent meeting of the Royal Medico-Chirurgical Society of Glasgow Prof. F. O. Bower, F.R.S., pointed out that the fact that ordinary plants are fixed in the soil and therefore stationary is so familiar that we pay little attention to it, and often remain quite blind to the far-reaching consequences which it entails. Since Darwin's book on the Movements of Plants was published, it has become common knowledge that plants do move, though under restrictions by their encysting walls. The protoplasts of an adult tissue can only move within their restricting prison, and the plant as a whole is immobile. The rooted position is, however, clearly effective for purposes of photosynthetic nutrition. The immobile plant can nourish itself and provide food also for the rest of the organic world; but its immobility imposes restrictions which have affected the whole course of plant evolution. So long as water is the medium in which plants live, and the gametes are motile in it, and especially if there are means of directing their movements to the right spot, fertilisation is possible for algæ. In land plants, however, difficulties at once arise. By peculiar specialisation mosses and ferns are still able to subsist on land, using "casual water" as the necessary medium for fertilisation, but are thus necessarily restricted to habitats where "casual water" is at all events sometimes available. On the other hand, the fully fledged land plant has to do without it. This is the reason for all those wonderful pollination mechanisms which have become the playground of botanical science. Mechanical ejection, air and water transit, and animal agency play their part; and pollination, the necessary step to fertilisation, is thus made possible for the immobile plant. When the seed is ripened a fresh difficulty arises in the spread of the seeds so that each shall have its chance. Again ejection, wind, water, and animal agency are called in with curiously parallel though distinct results.

Prof. Bower went on to state that there is yet another disability following from the immobile habit. The plant is the passive victim of predatory animals, being unable to escape by speed or cunning. Pasture grasses and clover, and any fodder plants are the natural prey of the grazing animal. Their sole resource is to restore as quickly as possible the parts that have been lost. Some plants develop poisonous or offensive juices, while others are no doubt protected from attacks by snails by the sharp crystals called raphides which are imbedded in mucilage; this swells as the tissues are gnawed, the cells rupture, and the sharp needles penetrate the delicate mouth of the marauder. It has been shown by experiment that even hungry snails avoid plants so protected. It thus appears that the whole evolution of plants has been overshadowed by the early sacrifice of mobility. Truly for them, "C'est le premier pas qui coûte." Encystment, while it secures protection, raises also many difficulties, and the further evolution of the plant has largely consisted in living them down. The wonder of it is that plants have succeeded as well as they have done. Necessity, with them, has indeed been the mother of invention.

THE KIND OF NURSE SHE WANTS.

To the Editor of The Lancet.

Sir,—I have just recovered from a troublesome prolonged but not very dangerous illness in which I badly wanted someone to wash me, to bring me my food, to make my bed, and in fact to attend to my physical needs. My doctor wished me to engage a trained nurse, a demand with which I should have been only too happy to comply if it had been possible to provide the extra accommodation, household service, and the meals more elaborate than the usual family ones. I could not face the prospect of having a guest who was entitled to a higher standard of comfort than that of my very modest household. The situation is a familiar one for which I can see no solution. Maybe there is no solution. I enclose my card and sign myself yours faithfully

A Middle-class Patient.

⁎⁎⁎ We deal with this letter in a leading article.—Ed. L.

THE CONSTANT CURRENT IN GRAVES'S DISEASE.

Dr. Stephen Portret, of Paris, has recently called attention (*Bulletin Officiel de la Société Française d'Electrothérapie*) to the fact that a certain number of cases of Graves's disease are resistant to radiotherapy, while they may be amenable to the older method of treatment by constant current. After giving details of the technique employed, Dr. Portret quotes a number of these resistant cases that seem undoubtedly to have improved under the electrical applications. It is presumed that the method would not be considered applicable to any very large proportion of cases; it would be unsuitable for cases in which tachycardia was present, due to permanent myocardial changes. Radiologists might, however, with profit bear in mind the possibilities of help from electrical methods particularly when the skin of the neck demands a rest from radiological exposures.

A STUDENT "DOCTOR."

At Woolwich an inquest was held on the body of a widow, 72 years of age, whose death was shown by post-mortem examination to have been due to chronic ulceration of the stomach and a ruptured blood-vessel. During her last illness she had been attended by a man, who on his doorplate described himself as "Dr. C. W. O'Donoghue," but who in the witness-box stated that he held the diploma of State Medicine in India, and admitted that he was not qualified to practise in this country. He stated, however, that he was a student, and that he was about to take his final examination. The woman had died while being examined by him with a qualified doctor, who had been invited to consultation. The coroner made forcible comment on O'Donoghue's story, saying that the case was a flagrant breach of the Medical Act, that O'Donoghue must have known that he had no right to practise as he had done, that he hoped that the Medical Defence Union would take action, and that O'Donoghue would fail to secure registration. He expressed sympathy with a qualified practitioner at his having been in anyway connected with such a man, who, he said, could neither spell medical terms nor pronounce them.

Dr. J. A. Marsden, in a communication, asks the question: Why is it practically impossible for cancer to grow in young persons? His own deduction is that spontaneous cure of cancer might take place in adults from the restoration of the influence which is protective in youth. He suggests that patients with this disease should be treated by interstitial grafting or by administering extract of the cells of Leydig.

An Address

ON

SOME USES OF DIGITALIS.

Delivered before the City Division of the British Medical Association

By G. A. SUTHERLAND, C.B.E., M.D. Edin., F.R.C.P. Lond.,

CONSULTING PHYSICIAN TO THE HAMPSTEAD GENERAL HOSPITAL; PHYSICIAN TO THE PADDINGTON GREEN CHILDREN'S HOSPITAL, LONDON.

We are all pleased with our successful treatment in cases of heart disease, but how much cause have we to congratulate ourselves on the direct treatment of heart disease by means of drugs? I do not think that in our medical armamentarium we possess any drug which acts directly and beneficially on disease of the heart. If we take the outstanding diseases of the heart calling for treatment we have to consider endocarditis, myocarditis, pericarditis, myocardial degeneration, valvular sclerosis and contraction, and adherent pericardium. These are the chief forms of organic heart disease. Will anyone maintain that these diseases are directly amenable to successful treatment by means of drugs? If any such there be it would greatly benefit the public and the profession if he were to convey his knowledge and methods to his medical brethren in such a way that they also may be able to treat these conditions successfully. So far as I know this has never yet been done.

If we consider the outstanding function of the heart, the pump-like action in maintaining the circulation, this great function is liable to failure in heart disease, and claims are made that the contractile power of the heart muscle can be improved and increased by the direct action of drugs. Pharmacologists teach this, students imbibe the information, become qualified, and go into practice believing it, and medical men pass the whole of their lives, honourably and successfully, with this dogma as a fundamental part of their creed. If an unbeliever asks for proof he is simply told that everyone knows it. I am one of those humble unbelievers who has hitherto failed to find any drug which will act directly and beneficially on the cardiac power of contraction.

Use of Drugs in Disturbances of Cardiac Action.

On the other hand, if drugs have been a failure in diseases of the heart, and have failed to improve contractile power in the heart muscle, they have found a great field of usefulness in connexion with disturbances of the cardiac action. These disturbances may be associated with sound or diseased hearts. They may be disturbances of rate or of rhythm or of both. They may arise in the heart itself, or be the result of defective blood-supply to the heart, or be caused by some condition of the blood, or may be nervous in origin. They may be indicated by an increase of the heart rate or a slowing. These disturbances are familiar to all under the names of auricular flutter, auricular fibrillation, heart-block, paroxysmal tachycardia, extra-systoles, &c. We may sum up these disturbances as being due to an abnormal rhythm or tachycardia or bradycardia. Unconsciously in the past many have successfully treated these disturbances, while they thought they were treating the disease of the heart or increasing its muscular power. Empirically the benefit was obtained in certain cases by counteracting the bad effects which these disturbances were producing in the heart's action, although the modus operandi was not understood or was erroneously interpreted. Thus, in cases of delirium cordis (now described as auricular fibrillation) digitalis was looked on as a drug which steadied the heart and improved the muscular tone and the contractile power. At the present time we are content to treat the disturbance which has arisen in connexion with auricular fibrillation, to reduce the excessive number of ventricular beats which have developed, and when this has been accomplished we can safely leave the muscular tone and the contractile power of the heart to do the rest.

In all of these disturbances the chief factor to be considered is the effect which the disturbance has on the efficient action of the ventricles. A marked disturbance of the heart may be present—for example, extra-systoles—but if the ventricular action is efficient the patient has no signs or symptoms of cardiac failure. On the other hand, if the ventricular action is deficient, if it is unequal to the carrying on of the circulation, symptoms and signs of cardiac failure will begin to appear. The effect on the ventricles is the standard by which we measure the importance of the disturbance present and decide as to whether treatment is called for or not. Similarly when such a real disturbance is present the success of our treatment will depend on the extent to which we can remove or check the disturbance, and thus leave the ventricle free and unhampered to carry on its work.

If the site of origin of these disturbances of rate and rhythm be inquired into, it will be found that the vast majority arise in the supra-ventricular tissues—that is, those parts of the heart which lie above the purely contractile tissues of the right and left ventricles. This applies whether the disturbance arises from the heart itself or is produced by outside causes through the blood-stream or nerves. In this sense it may be said that the ventricular muscle is protected to a great extent from disturbing factors which fall first of all on the supra-ventricular tissues. It follows, therefore, that disturbances in the rate and rhythm of the ventricles are always secondary to and dependent on some form of disturbance in the supra-ventricular tissues. These tissues are collectively described as the conducting tissues of the heart, and include from start to finish the sino-auricular (*s.a.*) node, the auricles, the auriculo-ventricular (*a.v.*) node, and the *a.v.* bundle. They are called the conducting tissues because their function is to conduct the impulse which starts the heart beat at the *s.a.* node through the walls of the auricles (which are also feebly contractile) to the *a.v.* node and thence through the *a.v.* bundle to the contractile tissues of the ventricles. It is on the regular and orderly functioning of these conducting areas of the heart that the ventricles depend for their efficient action. It is as a result of some disorder or disturbance in the conducting areas that symptoms of cardiac failure appear and medical advice is sought in a very large proportion of all cardiac cases.

The conducting tissues are of great importance also from the fact that it is on them that the vagus, the chief controlling nerve of the heart, acts. If the vagus nerve be stimulated there follows a depression of the *s.a.* node so that the heart rate is slowed, and also a depression of the conducting areas so that the *a.v.* interval is lengthened. As the commonest cause of heart weakness and failure is over-activity or over-excitability of some part of the conducting tissues, it would be of the greatest advantage to us clinically if we had some drug whose effects would tell on the conducting tissues more especially, by enforcing the controlling action of the vagus nerve. Such a drug we possess in digitalis.

Failure of Compensation.

The signs and symptoms of failure of compensation are well known, but what is "failure of compensation," and on what does it depend? We shall all agree that there is a failure on the part of a heart already diseased to carry on the circulation successfully or as successfully as the lesions present had previously allowed. You will find it stated that an increased cardiac rate is one of the commonest evidences of cardiac insufficiency or failure of compensation. You will also find it stated that the ventricular action is so feeble that the heart never empties itself, and as compensation for this the rate is increased. Both of these statements are misleading. An increased cardiac (ventricular) rate is not an evidence of failure of compensation, but it is the commonest cause. When ventricular action is feeble an increase in rate will never strengthen it, for one finds that pari passu with the increase of rate the ventricular contractions become feebler and less effective. There is no clinical evidence that ventricular action is ever improved by increasing the rate of the heart. In the case of healthy hearts muscular effort on the part of the body generally, as in running, will at once lead to increase of rate, which ensures a rapid flow of blood through the tissues. It is this rapid flow of blood which enables the muscular activity to go on, but a time comes when the heart can stand the rapid rate no longer and must have rest. In the case of diseased hearts we find this inability to maintain a rapid rate successfully much more pronounced, so that no attempt is ever made in therapeutics to improve the cardiac power by increasing its rate above the normal.

The term "failure of compensation" implies that the compensatory changes which the heart has brought about by its own inherent powers have broken down, but is this really so? Take the familiar example of auricular fibrillation with a sudden onset which is the commonest type of failure of compensation. Here the patient passes quickly from a condition of comparative comfort into one of the greatest cardiac distress. This development is to be explained not as due to any change in the compensatory apparatus, but as due to the onset of a new rhythm with a marked increase of rate, which has thrown the heart out of working order. The compensatory changes are ready to resume their function as soon as the disturbing factor has been removed or its effects have been controlled by slowing of the ventricular rate. The same applies in the majority of cases we meet with in practice, and the question of compensatory failure so called may be eliminated from our investigation into the therapeutic uses of digitalis. In a minority of the cases we are called on to treat there is a failure of compensation when the muscular power of the ventricles finally gives out, without other disturbance, but this is not the class of case in which we can hopefully use digitalis, or anything else.

Failure of compensation is a misleading term in the majority of cases, but it has established itself and we must accept it and explain as clearly as possible the condition referred to. I should describe that condition as the development of symptoms of cardiac failure owing to a disturbance in the conducting tissues causing a change in the rate or the rhythm of the heart, and accompanied by a rapid ventricular rate. In some cases there may be a disturbance of the rhythm of the heart without any material change in the rate of the ventricles, and with possibly an actual slowing of the ventricular rate. In such cases we do not find that digitalis as a therapeutic agent is of any use. The value of digitalis is shown in those cases in which there is a disturbance in the conducting tissues causing a rapid ventricular rate. When we say that digitalis is beneficial in cases of failure of compensation it will be found that the cause of the failure is the disturbance just described.

MODE OF ACTION OF DIGITALIS.

It will be admitted that as practitioners of medicine it is very desirable to know in the case of any particular drug what its mode of action is, what type of case is suitable for its use, and what the exact results are which may be looked for. As regards digitalis, this has now been achieved. On the other hand, it is not desirable that we should go on using this drug in unsuitable cases or indiscriminately in all cases of heart disease merely because of some physiological or pharmacological experiments, or because of dogmatic and text-book teaching. I shall try to give you a practical outline of the uses of digitalis in clinical medicine, dealing with the mode of its action in therapeutic doses, the class of case in which it may be expected to prove useful, and also the class of case in which no benefit may be expected.

I would ask you first of all to dismiss from your minds any impression you may have gathered that digitalis is a great cardiac tonic which directly augments the tonicity or the contractile power of the heart. Neither digitalis nor any other drug has been shown to have any such action in clinical work. One can go further and say as regards digitalis that it has not been proved to have any direct therapeutic action on the heart muscle. On the other hand, there is an accumulation of evidence, clinical and otherwise, amounting to proof, that digitalis stimulates the vagus, the great controlling nerve of the heart, probably by acting on the vagal centre, and more especially the vago-cardiac centre. The result of stimulation of the vagus is a depression or inhibition of the activity of the supra-ventricular tissues we have described as conducting. This result is manifested by a slower production and discharge of impulses at the sino-auricular node, the pacemaker of the heart, and by a slower rate of progress of the impulse through the conducting tissues, so that the *a.–v.* interval is lengthened. Thus the final and important result of stimulation of the vagus is a slowing of the ventricular rate. This action is much more pronounced in hearts with an abnormally rapid rate than in hearts with a normal rate.

If we approach the question from the clinical side we find in cases suitable for digitalis that there is a rapid ventricular rate, and our object is to produce its slowing. In order to stimulate the vagus it is no use giving small doses, such as five drops of tincture of digitalis three times a day. That may lead to a gentle but ineffective stimulation of the vagus, but what we desire is to get the vagus thoroughly gripped by digitalis so that its full controlling powers are brought out. Full doses of digitalis are called for if good therapeutic results are to follow. Assuming that these have been given, we shall find the vagus inhibition will fall first on the *s.a.* node, and will limit the rate of production and discharge of stimuli. The rate of the heart beat having been reduced at its source, fewer stimuli reach the ventricles, and the result is a reduced rate of the ventricular contractions. In many cases of disease the *s.a.* node is not in action as the heart beat starts elsewhere—for example, in auricular flutter and fibrillation. In these cases the vagus will act on some other part of the conducting tissues, especially the *a.v.* node and bundle, and will diminish the rate of conduction through those tissues. The result will be the same, a slowing of the rate of the ventricle owing to the blocking of many of the stimuli which had been reaching it. This, then, is the action of digitalis which we apply therapeutically. Digitalis is given in full doses, it stimulates the inhibitory action of the vagus, which leads to a depression of the over-activity in the supra-ventricular tissues, and results in a slowing of the ventricular rate. You may take it as an aphorism—no slowing of the ventricular rate, no benefit from digitalis.

CLASS OF CASE WHERE DIGITALIS MAY PROVE USEFUL.

Reference has already been made to the absence of any specific drug treatment in acute and chronic heart diseases. In the treatment of disease of the pericardium, the myocardium, and the endocardium, as such, digitalis plays no part. Far less is it to be regarded as the routine treatment on the detection of a systolic murmur, a dilated heart, or a re-duplicated second sound—as some of us are old enough to have seen done. The class of case suitable may be described as that in which certain disturbances have arisen in the supra-ventricular tissues and have led to an increase in the ventricular rate. The normal mechanism of the heart beat has been thrown out of order, it may be by a disturbance of the rate or a disturbance of the rhythm, but if the result is an increase of the ventricular rate with signs of cardiac failure, then digitalis is called for. I do not state that all cases falling under this category will benefit from digitalis, or that they will show that marked slowing of the ventricular rate which is our aim and object. On the contrary, we shall find later that certain conditions may modify or prevent the beneficial action of digitalis, and that many cases which appear suitable fail entirely to react to digitalis, probably owing to the presence of unknown factors. There are still many problems left about the action of digitalis for our younger colleagues to work at and solve. In the past great emphasis was laid on valvular lesions, and special indications were given as to the line of treatment of the various lesions with digitalis. In the use of digitalis we now pay no attention to the valvular lesion, but deal only with the disturbance present in the heart. Digitalis is equally serviceable whether the valvular lesion be mitral regurgitation or mitral stenosis or aortic regurgitation or a combination of these, provided that for other reasons it is called for. No variety of heart disease, per se, is an indication for the use of digitalis, but in every form of heart disease accompanied by a rapid ventricular action digitalis may be useful.

A good deal of discussion has taken place as to whether digitalis is as effective in cases of rapid and regular heart action as it is in cases of rapid irregular action. The great example of the latter is auricular fibrillation, and the reputation of digitalis is based on its beneficial action in that condition. The teaching of Mackenzie on that subject is now universally accepted, and he has shown that the benefits to be obtained from digitalis are more strikingly seen and more hopefully expected in cases of auricular fibrillation associated with rheumatic disease of the heart than in any other condition. It is generally agreed that the beneficial effect of digitalis in this connexion is by the slowing of the ventricular rate through the inhibitory action of the vagus acting on the *a.v.* node and bundle and the induction of partial heart-block. In the case of auricular flutter we have a condition in which the disturbance in the auricles leads to a great increase of rate but a regular action. The ventricular result is always an increase of rate, but the contractions of the ventricle may be regular or irregular. In this condition, also, the results of digitalis treatment are very satisfactory. In these two conditions the rhythm of the heart beat has been disturbed because the starting-point is always ectopic, as Lewis calls it, that is to say, at some point away from the normal pacemaker the *s.a.* node. In another class of case the rhythm of the heart is normal, but the rate is greatly increased although perfectly regular. I have recorded a series of cases in early life, and Dr. Henry Christian has recorded others in later life, in which great benefit was obtained from digitalis in diseased hearts with a rapid and regular action. In such cases the presumption is, and tracings confirm it, that the inhibitory action of the vagus tells on the *s.a.* node and depresses its activity. So that when other conditions are favourable the presence of a regular cardiac action as opposed to an irregular one should not be considered a contra-indication to the employment of digitalis.

Cases of chronic heart disease as met with in practice may be divided into two classes, those which are the result of rheumatic infection and those which are not. The second class comprises all the chronic degenerative changes met with in advancing years which are late infective, or toxic, or senile in origin. If we take the cases in which digitalis appears to be called for, it will be found—as generally agreed—that the beneficial effects are more strikingly manifested in those with a rheumatic origin than in those where other forms of degenerative change are present. Why this is so is somewhat difficult of explanation. If the views previously expressed be accepted, we do not expect digitalis to act directly on the heart but only on the vagus nerve. There is no suggestion that the vagus itself has been specially affected by the rheumatic infection or by chronic degenerative changes of any other kind. It would appear, therefore, that in rheumatic cases the cardiac tissues, and more especially the supra-ventricular tissues, have been so altered by the rheumatic infection as to make them more susceptible to the inhibitory action of the vagus nerve when stimulated by digitalis. If we take the cases in these two classes in which digitalis has failed to do good, although pushed to its full effect on the vagus and under conditions when the cardiac symptoms seemed favourable, it will be found that the majority of these failures occur in the non-rheumatic cases.

If we say that digitalis is suitable in cases of disturbances of the cardiac action, which occur in a diseased heart, and which are manifested by a continuously rapid rate of the ventricles, and a weakening of the ventricular contractions, we sum up the cases in which digitalis has been found to be and proved to be of great service. If this limitation be accepted you will see that a great number of conditions are ruled out. By specifying a diseased heart we at once rule out all the functional disorders of the heart, and the diseases of an extra-cardiac nature, which react on the heart. By specifying a continuously rapid rate, we exclude all forms of heart disease associated with a slow pulse, such as heart-block. We also exclude cases in which the heart-rate is normal, for it is my experience that digitalis cannot be hopefully or beneficially used in such cases. Paroxysmal tachycardia is also excluded, and rightly, because digitalis will do good only if and when the paroxysms are changed into a prolonged and continuous tachycardia. By specifying weakened and inefficient contractions of the ventricles we exclude those cases in which a diseased heart is merely quickened in its rate—as it is on any call for extra effort or under nervous excitement—without any other effect on its efficiency. It is only when the rapid rate leads to the production of some symptoms on the part of the patient, an evidence that the circulation is impaired, that digitalis is called for and will prove really serviceable. Some may think that I have reduced the use of digitalis to a very small and select number of cases, but if you analyse your own cases in which digitalis has had a demonstrably beneficial effect, you will probably find that they fall into the category defined above as suitable for digitalis.

Certain Factors which Interfere with the Action of Digitalis.

It must not be assumed that in all cases of weak and rapid cardiac action digitalis is called for. It should not be made a routine practice to give digitalis in all such cases. The results will often be disappointing, and further, the patient will often be needlessly alarmed when he discovers that digitalis has been given. For the public are now firmly convinced that the use of digitalis implies the presence of heart disease, and that heart disease means a liability to drop dead at any moment. In cases of chronic alcoholic poisoning one frequently meets with certain symptoms suggestive of cardiac failure such as an enlarged liver, a rapid heart, and a feeble pulse. To give digitalis in such a condition of poisoning is useless and it needlessly alarms the patient.

The chief factor which interferes with the action of digitalis is a condition of active toxæmia. In Graves's disease we have a cardiac disturbance which would appear suitable for digitalis therapy—namely, a persistently rapid heart. If the disease is active—that is to say, if the system is being poisoned by an excessive amount of thyroid secretion—it will be found that the use of digitalis in full doses has no effect. When the active symptoms have subsided and the toxæmic condition has gone, the heart may have been damaged, as shown by the presence of auricular fibrillation or a rapid rate. At this stage digitalis may be given and, as a rule, with great benefit. In the case of other poisons, such as alcohol in excess, the same results will follow, and it is useless to give digitalis until all signs of active toxæmia have subsided.

It is now generally accepted that in acute pyrexial conditions digitalis does not slow the heart and that no benefit follows its use. It does not seem to matter whether the pyrexia is the result of some local inflammation or of some general infection. There are probably several reasons for this failure to obtain benefit from digitalis. The raised temperature of the blood may stimulate the *s.a.* node and lead to an increased rate, or the stimulation of the sympathetic nervous system may be so great as to overpower the vagus control. There are often toxic elements in the blood-stream which may directly stimulate the *s.a.* node to such an extent that nervous control is lost. Be the reason what it may, we have much evidence of this uselessness of digitalis during pyrexial conditions and we have no evidence to the contrary. It would appear that during pyrexial disease digitalis does exert its influence on the vagus nerve, but that no effect is produced on the heart rate because a more powerful stimulant is at the time acting on the heart. I have evidence to show that if digitalis has been given in full doses during acute rheumatic disease with pyrexia, and *if the temperature falls*, we may get such a marked slowing of the pulse as to show clearly that the inhibitory action of the vagus had been brought into action. As unfortunately we are not able usually to fix definitely the duration of a pyrexial illness, we cannot employ digitalis with any confidence, although those who employ digitalis as a routine treatment in pneumonia have some support for their action. Even in a disease of fairly fixed duration like lobar pneumonia, I do not know of any series of cases showing definite evidence of benefit from digitalis. Repeated disappointments have led many to give up using digitalis in pneumonia.

If we contrast the two classes of cases, those in which digitalis may be expected to do good and those in which it may not, we shall find :—

1. That digitalis is serviceable when the disturbance in the heart rate arises in the cardiac tissues, and that it is not useful when the disturbance reaches the heart from without—i.e., through the blood-stream or the nervous system.

2. That the therapeutic benefits of digitalis are obtained when the later manifestations of heart disease have appeared and not in the acute inflammatory or actively toxæmic stages.

CLINICAL INDICATIONS FOR DIGITALIS.

What are the clinical indications for the use of digitalis ? Some are content to rely on an examination of the heart and pulse. There may be present some valvular murmurs, or alterations in the heart sounds, or changes in the size of the heart, but these are of no value in estimating the efficiency of the cardiac power. In the later stages of disease with which we are dealing such changes have probably existed for a long time. So that an examination of the heart can never by itself be made the basis of our treatment. A weak pulse will not decide the matter because no one ever felt a strong pulse when the heart was beating 140 times a minute. Every heart beat at that rate is weak and the pulse is correspondingly affected. The sphygmomanometer gives an appearance of scientific accuracy to a medical examination, but it is useless as a guide to the need for digitalis. In the typical case of auricular fibrillation there is no constant arterial pressure, for it becomes as irregular as the action of the ventricles. While we should carefully examine heart and pulse for comparison later on with the conditions after treatment, we must look elsewhere for the indications as to immediate treatment. Before treating the patient for cardiac failure we must have evidence that there is cardiac failure. Such evidence is to be obtained solely from the symptoms complained of by the patient and the signs in his tissues that the circulation is defective. In other words, a patient who requires digitalis has definite symptoms of which he is conscious and which are probably distressing him, and sooner or later he shows the presence of œdema in the lungs or extremities, engorgement of the liver, and congestion of the kidneys as manifested by a scanty amount of urine. The outstanding symptom is breathlessness, noticed at first on slight exertion, and increasing by degrees to breathlessness even at rest, and orthopnœa. When breathlessness is present, with or without some œdematous effusion, and when the heart on examination is found to be the organ at fault, and when the ventricular rate is rapid—that is the time to give digitalis. In suitable cases there is no haphazard action of digitalis. The doctor, however sceptical he may be about drugs, can see the good effect produced, and what is more, the patient, however sceptical he may be, is soon conscious of the relief which has followed.

DOSAGE AND ADMINISTRATION.

Digitalis is a powerful drug and may be dangerous if unskilfully used. Perhaps that is why text-books and pharmacopœias fail to indicate the full efficiency of digitalis by playing for safety with small doses. There is no doubt that the real merits of digitalis can only be learned by experience in dealing with many and different classes of cases. There are many points in common between digitalis and alcohol. Some call alcohol a tonic and others call it a poison. Both are right—it is a question of dosage. Some call digitalis a tonic, others call it a poisonous drug. Both are right—it is a question of dosage. Some give alcohol for its sedative qualities, others give it as a stimulant—and the same applies to digitalis. Both views are correct and both results can be obtained in suitable cases. The controversies over the use of alcohol are interminable, whereas as regards digitalis we have much more precise knowledge and much more agreement.

The first point to be remembered is that digitalis has to be given in such amount as to produce the required effect, which is slowing of the ventricular rate. This represents a considerable amount of digitalis and there may follow certain toxic symptoms. Our aim and object is to produce the maximum therapeutic effect with the minimum toxic effect. Some are so anxious to avoid the latter that they never succeed in obtaining the former. The minor toxic effects do not harm the patient, and are really helpful often as an indication when to stop the drug. It is only when they are ignored and the drug is continued that the really serious toxic effects on the heart and other parts of the body will be produced. Speaking generally, we find that for an ordinary effective course of digitalis from 4 to 6 drachms of a standardised tincture of digitalis will be required. The amount usually ordered per diem is from 1 to 1½ drachms, according to the urgency of the patient's symptoms. When 3 drachms in all have been taken, the amount is fixed at 1 drachm per diem until the heart rate is slowed to 80 or until vomiting or headache or diarrhœa supervenes. Very often the two occurrences are simultaneous—that is to say, nausea comes on and the heart rate is found to be distinctly slowed. You will find that it is the cumulative effect of a considerable amount of digitalis given in a short space of time which tells on the vagus and slows the heart. If we give tincture of digitalis in 5 or 10 minim doses thrice daily we may in time give a much larger amount of digitalis without producing an effect on the heart or anything else, because the destruction or excretion of digitalis is so complete. In practice, therefore, it is now customary to give from 4 to 6 drachms of tincture of digitalis spread over from four to six days. More recently massive doses of the tincture have been tried, 3 to 4 drachms in 24 hours, and good results have been obtained more quickly than by the slower method. While this treatment by massive doses may be useful in urgent cases—that is to say, when the patient's distress is very great—it has this disadvantage, that some patients are intolerant of digitalis and develop toxic symptoms on small amounts. If such a patient is treated with massive doses, the toxic phenomena ensuing may seriously interfere with the prospect of recovery. For ordinary cases which appear to be suitable for digitalis therapy if 6 drachms have been given without producing nausea or slowing of the heart rate, it is advisable to stop the drug for 24 or 48 hours. If no change takes place during this time the drug may then be resumed for a few days in doses of 45 minims of the tincture daily. But given a standardised preparation of digitalis or of digitalin, one usually finds a definite result when the amount taken corresponds to 6 drachms of the tincture of digitalis. If we watch the patient as regards functional effects on the heart rate or the onset of nausea and vomiting, we are not likely to meet with any of the seriously toxic effects, such as prolonged vomiting and diarrhœa, or on the heart itself, coupled beats and heart-block. Finally, it may be noted that children benefit as much as adults from digitalis, but they require much larger doses in proportion to their size. A child of 10 or 12 years with a chronic rheumatic heart and rapid rate, and failure of the circulation, will take from 45 to 60 drops of tincture of digitalis daily, or its equivalent, with great benefit if administered under the precautions given above for adults.

NOTES ON THE

EPIDEMIOLOGY OF MALARIA IN SOUTH-EAST RUSSIA.

BY MELVILLE D. MACKENZIE, M.D. LOND., D.T.M., D.P.H.,
SENIOR MEDICAL OFFICER, FRIENDS' RUSSIAN FAMINE RELIEF UNIT, SOUTH-EAST RUSSIA.

THE present widespread epidemic of malaria in South Russia is of deep interest both from a medical and a political point of view. Over enormous tracts of land, where subtertian malaria was unknown and tertian malaria rare, these diseases are now almost pandemic—up to 90 per cent of the population being affected in many areas. At the time of the famine in the Volga valley thousands of refugees travelled 1500 to 2000 miles to Turkestan where wheat was obtainable (November, 1921–March, 1922). On the return of these peasants after the harvest of 1922 malaria broke out in pandemic form throughout South-East Russia. The epidemic spread steadily throughout the winter, with the thermometer varying from 20° C. to 30° C. below zero from November until March.

Factors Favouring Spread of the Disease.

The spread of the disease during the extreme cold appeared to be due to the fact that the drinking-water butt, combined with the almost tropical heat of the log-houses of the peasants, offered an ideal breeding place for anopheles remaining in the huts from the summer. During the intense cold of winter both larvæ (in the water-butts) and adult anopheles (in dark corners) could be readily found in a large proportion of the peasants' houses adding to the large number of varied species of insects always existing in these places. A marked increase in the number of mosquitoes in a house occurs after a bundle of firewood has been brought in from the marshes. The firewood is covered deeply in snow; when brought into the log-huts it is dripping wet, and is stacked in a corner of the building, where it remains wet for some days owing to the high degree of water saturation of the air in the almost hermetically sealed houses. From the regularity with which an increase of mosquitoes is associated with the arrival of firewood in a house, and the excellent breeding conditions formed by the wet wood bundles in the hot houses, it appears possible that the eggs of certain mosquitoes laid in the cracks of the trees and dead wood in the late summer, and protected by the snow retain their vitality in spite of the intense cold (−30° C.). I have no evidence that this applies to anopheles.

Extent and Distribution of Epidemic.

The extent of the newly affected districts of Russia is limited by Nijni-Novgorod and Moscow in the north, by the western frontier of Russia in the west, and by the Black Sea in the south. This includes the whole of the Ukraine, Georgia, and the Caucasian provinces, the Black Sea provinces, and the whole of the south of the Volga valley. In the south-east the affected areas become continuous with the old endemic centres in Turkestan. The general incidence figures given by the Russian authorities are probably very inaccurate, as there exists little or no machinery for the collection of the crudest statistics. In practice, notification of births and deaths is only carried out in some of the larger towns and the notification of infectious and other diseases is not compulsory. The accuracy of statistics is further impaired by the very small percentage of the infected who see a doctor, owing to lack of transport (due to the death of almost all horses during the famine) and to the long distances (which are greatly increased by the small number of surviving doctors), added to the fact that the shortage of quinine and the large number of cases make it improbable that the patient will receive a dose of quinine after perhaps two or three days' journey. In this connexion it must be remembered that the great majority of the Russian population consists of country dwellers. There is no doubt, however, that a widespread epidemic of malaria exists in South Russia, with a very high rate of incidence amongst the population. The whole of the figures given below were obtained by English workers in the laboratories and clinics of the mission, and are largely based on 14,000 examinations in the unit's laboratory at Buzuluk during the six months, November, 1922–May, 1923.

The district in which I had an opportunity of noting some features of the epidemic was that of Buzuluk Ooyezd—a district approximately the size of Wales and with a mixed population of Tartars, Russians, Cossacks, and Khirghiz, totalling approximately 400,000. The population is widely scattered, the villages in some districts being 50 miles apart and 120 miles from the railway. The district includes forest (one-third), rivers, marshes, and steppeland, and has a maximum temperature of 102° F. in the summer and −30° C. in the winter. In this district the population was suffering from post-famine debility (one-half of the original population had died from famine and typhus fever), scorbutic diseases, nephritis, and dysentery; grass was still (in the winter, 1922–23) being mixed with rye-flour to make bread. Malaria first appeared in this district in October, 1922; and Chart 1 gives the number of persons applying for treatment in the Buzuluk town clinic (population 16,000 approx.) in the first six months. By March, 1923, between 60 per cent. and 70 per cent. of the whole population were suffering from the disease, the incidence being between 90 per cent. and 100 per cent. in most of the districts.

Types of Malaria Found.

Chart 2 shows the percentage of each type of malaria. It is to be noted that whilst subtertian malaria formed 35 per cent. of the total number of positives in November, 1922—i.e., immediately after the introduction of the disease to the district—both this type and quartan steadily fell until February, 1923, and have remained low (2 per cent. to 4 per cent.). Tertian malaria, on the other hand, has risen steadily in incidence, suggesting that this is the type that will remain permanently. This chart should be read in conjunction with Chart 1. Clinically, the cases presented all the characters of very severe malaria. During the winter, when the percentage of subtertian cases was at its height, there was a high mortality for which figures were unobtainable. It is interesting to note that of members of the unit, one who had been in perfect health throughout developed subtertian malaria three weeks after leaving Russia, the blood showing a heavy infection with small rings and crescents. This attack of malaria, which was due to a latent infection, was precipitated by an attack of relapsing fever and developed immediately after the latter.

Distribution of Quinine.

It was obvious that any efforts at hydro-technical control were useless in view of the enormous areas affected (all Southern Russia), the need of the water for irrigation, the indolent nature of the Russians, and the fact that most of the population were unfit to work. It was decided, therefore, to concentrate on a widespread distribution of quinine, this action being justified by the fact that the pandemic nature of the outbreak was largely due to the physical condition of the population—owing to the disease peasants could not plough, were unable to collect wood for warmth, to look after their animals, or even to carry the rations issued them by the relief unit. A prolonged quinine treatment enabled them to break the vicious circle of physical debility and malarial infection, and, moreover, reduced very considerably the number of human reservoirs of the disease.

The quinine was in the first instance issued to hospitals and practitioners. This proved unsatisfactory, as quinine became extremely valuable with the increase of the epidemic. In the case of practitioners the number of patients applying for treatment was so great that uselessly small doses of quinine were given to each patient, which resulted only in temporary relief. In hospitals the quinine was sold by the attendants or the patient himself, the latter hiding quinine under the pillows of his bed and accumulating a considerable quantity, after which he discharged himself and sold the quinine in the bazaar at 1*s.* (1,000,000 roubles) for 5 gr. Much quinine was wasted by its issue to other cases than malaria by reason of the absence of laboratory control. A bacteriological laboratory was therefore ordered from England in 1922. A series of educated Russians—mostly university students—were trained by the permanent English worker in the diagnosis of malaria, the administration of a clinic, and the issuing of quinine, a course lasting three months. As each student qualified he was sent out into the district to open a clinic on the lines of that in which he had been himself trained.

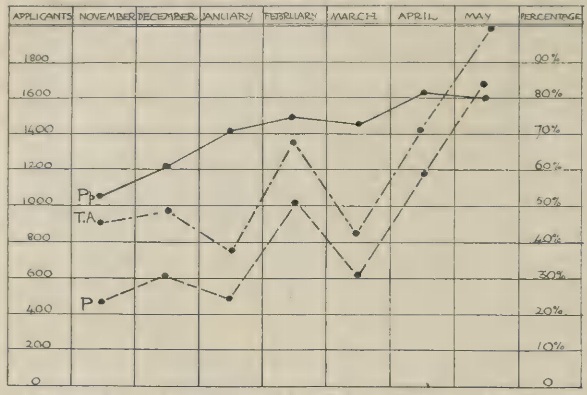


CHART 1

SHOWING TOTAL NUMBER OF APPLICANTS AND PERCENTAGE FOUND MICROSCOPICALLY POSITIVE DURING 6 MONTHS NOVEMBER 1922 TO MAY 1923

Pp, percentage of positives; TA, total applicants; P, positives.

The blood of every patient presenting himself at one of the clinics was examined microscopically, three examinations during fever being done before a case was declared negative. Positive cases were only treated upon a promise to continue to attend the clinic for two months in order to get a complete course. Few failed to keep the promise, as such cases were refused treatment at a later date should the disease recur. The fear of the disease was so deep, and the incapacity for agricultural work that it produced so great, that very few ran the risk of not being able to have treatment; practically, therefore, it was possible to obtain a satisfactorily long quinine treatment. A record card of each patient showed what attendances he had made and how many he had still to make. All quinine was actually swallowed at the clinic. The quinine given was a solution of the bisulphate in water and adults received 20 gr. as a single dose each day for a week and 15 gr. as a single dose twice a week for two months, the dose being varied proportionally for children. Though the patients varied from babies a few months old to old people no catastrophe or ill-effect has resulted from the large doses employed for ambulatory cases. The efficacy of this treatment is shown by the number of relapses (including reinfections) amongst patients (Chart 3).

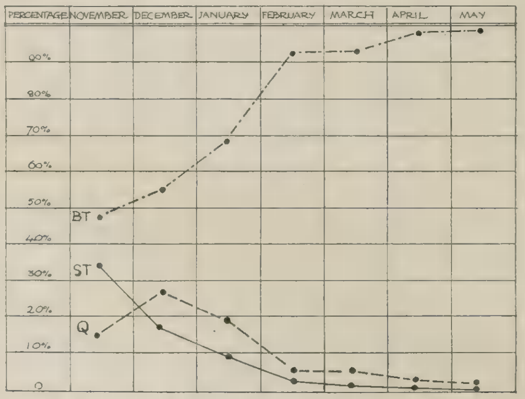

CHART 2

SHOWING RELATIVE INCIDENCE OF TYPES OF MALARIA DURING 6 MONTHS NOVEMBER 1922 TO MAY 1923

BT, benign tertian; ST, subtertian; Q, quartan.

The facts that the quinine issued from the unit clinics was the only quinine existing in the district, that it was consequently impossible for patients who relapsed to go elsewhere, and that each clinic dealt with a population isolated by distance, gives the relapse figure some value, in estimating the importance of the prolonged treatment. In March, amongst the 1500 cases treated, the number of old patients who had relapsed was 45. The increase to 180 in April is due to the re-infections during the thaw floods—the small number of re-infections being determined by the large proportion of the population undergoing the two months' treatment and having quinine in their blood. In a total of 5738 persons treated in the six months there were only 380 relapses and re-infections.

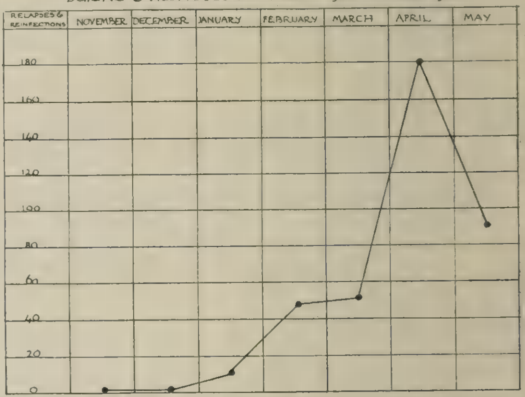

CHART 3

SHOWING NUMBER OF RELAPSES INCLUDING REINFECTIONS DURING 6 MONTHS NOVEMBER 1922 TO MAY 1923

Probable Effect of the Epidemic upon South Russia.

The effect of the epidemic on the future of Russia will probably prove to be greater than that of the Revolution. From a healthy country inhabited by a virile, energetic peasant population, and entirely non-malarial throughout its greater extent, the whole of South Russia is now probably the most malarial country in the world. The hopelessness of eradicating the mosquito in view of the enormous areas concerned, combined with the easy-going nature of the Russian and the low standard of education of the majority, make it probable that a great degeneration, comparable with the effect of malaria on ancient Greece, will in the next 20 years alter the type of the whole population of these Cossack districts and will threaten to overwhelm the rest of Russia. Had it been possible, as it was practicable, to quarantine all refugees arriving from Turkestan (as was done with cases of suspected cholera and typhus), the infection of the mosquito could have been prevented to a large extent, but it was impossible to persuade the authorities to allow the formation of a quarantine camp, where refugees could have been treated with quinine if found to be suffering from malaria on arrival.

The chief points of interest in the epidemic as I saw it may be enumerated as follows: 1. The rapid spread of the epidemic in the extremely cold winter months in Russia. 2. The mode of spread through the means of the infected water-butts of the peasants' houses. 3. The fact that subtertian malaria reached its maximum in November, December, and January and afterwards almost disappeared. 4. The monthly alteration in the quartan incidence (Chart 2). 5. The extreme susceptibility of a population weakened by famine and disease. 6. The practical difficulties met with in the uncontrolled quinine distribution in a malarial country and the need for constant laboratory control. 7. The small number of relapses (including re-infections) after prolonged quinine treatment. 8. The necessity for seeing the quinine actually swallowed at the clinics. 9. The absence of risk in the routine high dosage of quinine in ambulatory cases. 10. The pandemic nature of the outbreak. An average for all our districts showed between 60 per cent. and 70 per cent. of the population to be infected and in most of the districts 90 per cent. and 100 per cent. The malarial cases showed an average of 57 per cent. of all out-patient cases at hospitals.

RHEUMATIC CARDITIS:

SOME PRINCIPLES GOVERNING ITS PREVENTION AND EARLY TREATMENT.

BY MARTIN O. RAVEN, M.D. OXF.,
MEDICAL OFFICER, HORSFALL WARDS, ST. MARY'S HOME, BROADSTAIRS.

ALTHOUGH the general public has to a large extent learnt to appreciate the modern clinical conception of infective disease, and has in consequence been roused to considerable efforts in combating tuberculosis and venereal disease, it is nevertheless not much better informed with regard to acute rheumatism than it was 100 years ago. The idea of a "rheum," causing a painful lodgment in the various parts of the body where it came to rest, is practically identical with the modern lay conception of constitutional rheumatism, and though it is nearly 100 years since Scudamore and Bouillard associated cardiac lesions with rheumatism, even a well-educated man of to-day, unless he has had personal experience of the disease, is usually unaware of that association.

Yet to the medical man the disease is daily manifest in patients of all ages. Osler alludes to the "long arm" of rheumatism, in ascribing to it a large proportion of the 50,000 annual deaths from heart disease in this country; and recent figures are still more emphatic. Langmead[1] states that in the London County Council schools there is actually more rheumatism than tuberculosis, and that in the special schools for physically defective children one-third of the cases are cardiac. In 1920 the statistics of the Invalid Children's Aid Association show that they had 996 cases of rheumatism, heart disease, and chorea in their charge, as compared with 1401 cases of all varieties of tuberculosis.

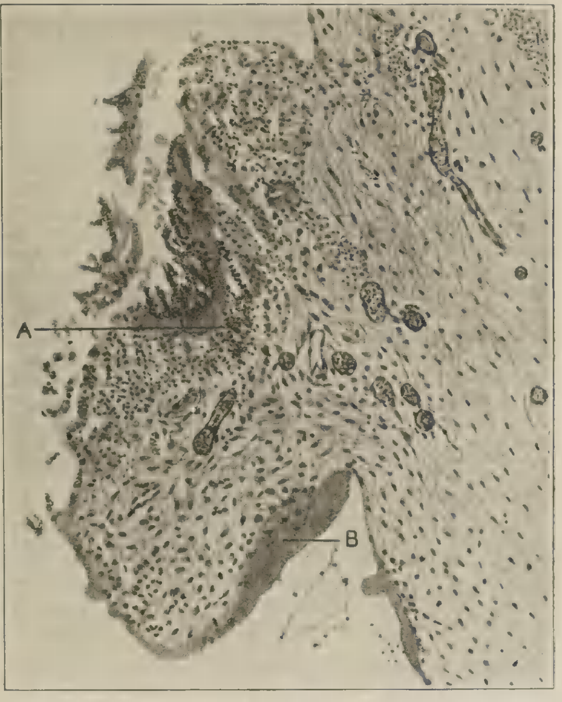
Literature of the Subject.

During the last century the teaching by Botrel that all chorea was of rheumatic origin, and the description of the rheumatic nodule by Hillier, were followed by Cheadle's conception of the "rheumatic state" in childhood and early adult life as an infective disease[2]—a conception which still holds the field. This conception was from the first strongly supported by the anti-rheumatic effects of sodium salicylate, and adequate doses of the drug at frequent intervals, in children as well as in adults, were insisted upon by Dr. David Lees[3] in his works upon rheumatic carditis. The work done under the stimulus of the chemical theory of the disease—which led Richardson to suppose that lactic acid, and Latham and Haig to suppose that uric acid, was the cause of rheumatic fever—needs only to be mentioned to show how completely such theories are rejected by the clinical thought of to-day, under the influence of the results of bacterial research.

But in spite of the discovery of numerous bacteria in immediate association with other clinical syndromes and lesions, those of acute rheumatism remain unassociated with any established causative organism. In 1900 and 1901, Poynton and Paine[4] claimed that they had demonstrated a diplococcus in 11 cases of acute rheumatism; this organism was found in the blood, pericardial fluid, granulations from the heart valves, nodules, heart wall, and throats of their subjects; inoculation of the organism into rabbits was found to produce arthritis, synovitis, early valvular murmurs, chorea, valvulitis, and pericarditis, and it was claimed to be the cause, not of all rheumatism, but "of all cases conforming to the usual type of the disease." These researches, though they still find considerable support—noticeably that of Beattie and Dixon[5]—have not been so fully confirmed that they command general acceptance. Horder[6] has remarked a general agreement that the vegetations of rheumatic endocarditis were, as judged by the present methods, bacteria-free, as also was the patient's blood-stream.

Rheumatic and Bacterial Lesions Contrasted.

Microscopic sections of the heart valve and musculature, of which the accompanying illustration is an example, taken from a case of infective (staphylococcal) endocarditis superimposed on a rheumatic history, illustrate the histological contrast between the rheumatic and the bacterial lesions, both types lying side by side in the same valve and in the muscle. The rheumatic lesions show lightly-stained fibrinous deposit and fibroblastic proliferation (Aschoff's nodes in the muscle); the infective endocardial lesion and a pyæmic abscess in the muscle show intense polymorphonuclear invasions of the areas.[7]



Section of mitral valve of a patient who died from secondary (staphylococcal) endocarditis. There was a long history of rheumatic heart disease. A, Area of intense hyperæmia and polymorphonuclear cell-exudation, the site of old rheumatic endocarditis. B, Area of rheumatic endocarditis, showing fibrinous deposit and fibroblastic proliferation beneath the endothelium. (From a drawing made by Dr. Joan Ross.)

However obvious, therefore, it is that acute rheumatism is infective in its origin, there is as yet no full warrant for saying that the infection is bacterial, and it is certainly remarkable, in contrast to many diseases with definite morbid lesions, that if there is a bacterium present in the very specific lesions of rheumatic disease, its identity has not been revealed by this time. Alternatives to a bacterial infection seem to be : (1) an exotoxin secreted by a bacterium lying elsewhere than in the specific lesions; (2) a filtrable virus. All these possibilities require further investigation; it is conceivable that there may be symbiosis in infection—e.g., that a streptococcus may be in close association with a filtrable virus.

General Position of the Disease To-day.

The existing uncertainty as to the cause of rheumatic diseases is undoubtedly an important factor underlying the very unsatisfactory state of affairs prevailing in the management of the disease to-day. One has only to imagine the discovery and bacteriology of a causative organism to be established to visualise the impetus which would be given to prevention, to diagnosis, to properly controlled treatment, and to the education of the public in the disease. There is no doubt that the established bacteriology of *B. tuberculosis* has been a great stimulus to the hygienic and clinical management of tuberculosis; the occurrence of the bacillus in milk and in sputum has had far-reaching effects in diagnosis and in the establishment of preventive measures; similarly the finding of the organism in the tonsils and decaying teeth of children has emphasised the desirability of tonsillectomy and of dental repair in thousands of cases of tuberculous adenitis of the neck. Yet, though there is no bacteriology in rheumatic corresponding to that in tuberculous disease, a great many facts are nevertheless so well established clinically as to justify systematic attempts to control this disease, similar to those already being made in the case of tuberculosis. In 1900 Caton[8] published a series of 86 cases illustrating the preventability of valvular disease of the heart by treatment of rheumatic endocarditis. In America the Society for the Prevention and Relief of Heart Disease has assumed an influential position, and in this country in 1923 Dr. Poynton[9] has brought forward considerable proposals, in which education of the public takes a prominent place, for the early detection of rheumatic symptoms and the consequent prevention of carditis. Finally, during a discussion opened by Dr. R. Miller at Portsmouth, the Council of the British Medical Association has been recommended to appoint a special committee to consider the best steps to be taken to combat the disease.[10]

Is Rheumatic Disease Infectious?

Newsholme,[11] in 1895, spoke of rheumatism as an acute infectious disease, having an epidemic prevalence in irregular periodicity. It may be asked whether it can be regarded as an infectious disease to-day. It is now generally admitted that phthisis is an infectious disease. W. St. Lawrence,[12] in New York, made an investigation into the incidence in families of rheumatism and tuberculosis. In 100 families, in each of which at least one member had suffered from a manifestation of acute rheumatism, he found the percentage of cases of actual rheumatism among all the exposed persons to be 14·8; a similar investigation in respect of tuberculous families, in each of which at least one member had active tuberculosis, revealed the percentage of actual cases among persons exposed to be 14·6, and he points out that "it is difficult to evade the proposition that rheumatic disease, and therefore cardiac disease, is communicable to a degree not generally imagined."

A London boy suffering from hitherto unrecognised and advanced heart disease was recently introduced into a seaside ward containing many rheumatic cardiac cases. He developed tonsillitis on the day of his admission, but by a mistake was not isolated for over 24 hours; a nurse shortly afterwards contracted tonsillitis, and for some time afterwards there were continual and irregular attacks of pyrexia and tonsillitis among the children in the ward. During this period one child with a rheumatic history contracted early mitral disease for the first time, after having tonsillitis; one case of severe adherent pericardium suffered from a severe recrudescence of the disease, and in two cases of old mitral disease relapse occurred, as indicated by recurrence of anæmia, tachycardia, and dilatation of the heart, and a return and intensification of murmurs which had been quite or nearly abolished—in one case by a long term of rest and treatment.

There is some evidence, therefore, that on grounds of public health alone the isolation of a child suffering from symptoms of rheumatic disease may be as desirable as that of a person suffering from phthisis.

Prophylaxis of Heart Disease in Rheumatic Cases.

Prophylaxis in the individual child may next be considered. W. St. Lawrence[13] made observations in 65 children who had had manifestations of rheumatic disease elsewhere than in the heart. These cases of "potential cardiac disease," as he has called them, were kept under observation and management for 4½ years; by the end of that time 25 per cent. of them had developed cardiac lesions of some sort; the remaining figure of 75 per cent. he regards as certain to fall, many of the children having had constant severe recurrence of rheumatic fever or chorea, and "such persons rarely failing to contract eventually a lesion in the heart"; he concludes that only when a child has remained free from recurrence of rheumatic manifestations for three years may recovery be regarded as fairly safe.

Further, of the 25 per cent. that developed heart lesions every one had had chorea, whereas of 100 children with cardiac lesions, who had not been under treatment, less than a quarter had had chorea at any time. St. Lawrence regards tonsillectomy as a most important factor in the management of these cases, and hence he concludes that this operation is highly effective in preventing recurrence in cases of acute rheumatism or rheumatic pains, but much less effective in preventing the recurrence of chorea. He draws a superficial analogy between active syphilis and parasyphilis on the one hand and rheumatic fever and chorea on the other, pointing out that the diseases in each case are much less amenable to treatment when the nervous system is implicated.

During the past year eight children who received during the summer of 1922 from 6 to 12 weeks' quiet life by the seaside have been observed. The hearts were all normal on their arrival at and departure from the seaside. They had all originally had chorea; in no case was tonsillectomy performed. They were re-examined after at least six months' life in London and daily school attendance, the results being as follows:—

3 cases	Heart normal; no more chorea.
1 case	Heart normal, but chorea recurred.
3 cases	Signs of myocarditis (excitable beat and dilatation); fresh chorea.
1 case	Aortic regurgitation.

Out of eight cases, therefore, who had had a short stay on the sea-coast, five showed recurrence of rheumatic symptoms.

Prevention of Relapse in Cases of Established Heart Disease.

Coming, thirdly, to the case of the child who has developed some degree of rheumatic cardiac disease, the time-element involved in the question of recovery is still more formidable. It has to be asked at the end of what length of time is a heart, which has once been infected, to be considered free from infection. In the absence of any kind of laboratory help, the answer is bound to be most uncertain, and even if a heart valve be freed from actual infection, it appears to become reinfected with disastrous ease in unfavourable cases. Cowan and Rennie[14] found that of 62 cases dying from chronic valvular disease at all times of life, no less than 39 showed acute endocarditis to be present at death—due, they consider, to reinfection of the valves previously injured by rheumatic endocarditis, while Poynton,[15] in recording a series of cases which seem to link up "simple" and "malignant" forms of endocarditis, suggests that such cases are those, not of superadded infection on a previously damaged valve, but in which organisms which have remained dormant in the tissues of the valve for years, have been reawakened to activity.

Children dying from heart disease may be said never to die from any merely mechanical defects inherent in the damaged valves; the cause of death is the toxic action of the rheumatic poison upon the essential part of the heart—the myocardium; and the observations of Cowan and Rennie make it appear likely that the same kind of toxic agent may often be present in cases dying from chronic valvular disease, leading to a poisoning of the already damaged myocardium. This hypothesis would account for the comparatively acute onset of symptoms leading to fatal heart failure, occurring in individuals who have for some years been known to suffer from valvular lesions without grave embarrassment, and a successful combating of the endocarditis would account for occasional recoveries in cases of heart failure where the outlook had seemed almost hopeless. In cases approximating to the "malignant" type, secondary organisms are perhaps deposited on the damaged valves or are brought by blood-vessels to the vascularised valves; but it is also to be regarded as possible that an infection having once occurred in a valve may be latent for years and then flare up again under suitable circumstances.

Thus there is at present no answer forthcoming to the question of the duration of valvular infection. But here again, in the absence of obvious constitutional signs of active disease—e.g., pyrexia and increasing pallor—clinical observation furnishes a principle of practical assistance. Just as an abnormal condition of the heart is indicated by abnormal physical signs, so where there is an observed change in the physical signs in progress, it is fair to assume that the lesion in the heart is itself undergoing change, and while such changes are in progress it is clear that the stage of activity of the disease has not been fully completed. And until that active stage is closed the heart should be given as much complete rest as possible, in the same way that a tuberculous hip is rested completely until all active signs of the disease have ceased.

Such a principle undoubtedly involves a long time element in the course of its effecting a recovery, for, as will be shown later, some of the changes in the physical signs take place very slowly. Moreover, when the cardiac condition has settled down to what seems a constant state, any increased amount of work put upon the heart must be very gradual, and, even when the patient is up and about, the question of possible relapse, from which even "potential" heart cases suffer so often, has to be considered. Such treatment should be undertaken under every kind of favourable circumstances possible; of these, fresh air, adequate warmth, good food, and a discriminating nursing supervision in order to ensure adequate physical and emotional restraint are the most important. The test of the efficiency of the treatment will be in the results as compared with the results of the usual forms of treatment available.

Results of Infection of the Heart.

In tabulating the results of infection of the heart the main difficulty lies in the very varying incidence of the infection upon the tissues of the heart. The myocardium, pericardium, and endocardium may be simultaneously or separately affected, and the endocardium may present single or multiple lesions. In the great majority of children suffering from chronic carditis there is a history of repeated attacks of chorea, rheumatism, or "growing pains," which clearly show that there is no system existing at present which is capable of preventing these recurring attacks. The usual history is that the children have gone into and out of hospitals several times, after which they are found to have a "weak heart." The special schools provided for such children by the London County Council constitute the best possible method of controlling these children's condition under the existing circumstances. Fresh air is abundant, medical supervision is regular, the children have a great deal of rest and are brought from and returned to their homes daily in special carriages.

Among 48 such children with a history of chronic rheumatic heart disease examined, the average time elapsed since the original infection was four years. the actual times varying from one to 11 years and under such circumstances the conditions of their hearts were found to be as follows:—

1. Normal hearts	5	cases.
2. Moderate muscular hypertrophy with systolic murmur	12	,,
3. Marked muscular hypertrophy with tumultuous heart-beat and rib-retraction	6	,,
4. Mitral obstruction (i.e., diastolic apical bruit) ..	12	,,
5. Mitral stenosis	7	,,
6. Aortic regurgitation	6	,,

These cases may be conveniently considered in three groups, according to whether the chief stress of the infection seems to have fallen upon the muscle, the mitral valve, or the aortic valve.

1. *Myocarditis.*—Myocarditis occurs in every case of rheumatic heart disease and is followed by some degree of cardiac dilatation and excitability of the heart beat. The nodes of Aschoff are so small as not probably to interfere with the conductivity of the muscle bundles of the heart, unless the condition becomes grossly aggravated by continually recurring infection. Slight dilatation of the heart is often accompanied by a soft systolic murmur, which is not necessarily endocardial in origin; in many cases under observation while recumbent, these systolic murmurs have been found to disappear completely. The cardiac dullness is estimated by palpation and percussion—especially by light percussion, as recommended by Dr. D. Lees.[3] The apex beat indicates the position of the lowest point of the left ventricle, and unless the chest is malformed—e.g., from rickety changes—is usually felt in the fifth left intercostal space, and the left border of the heart curves gradually inwards and upwards from this position. The right ventricle can sometimes be palpated through the epigastrium and diaphragm, but a definite enlargement of it can only be estimated when there is also hypertrophic change. The position of the border of the right auricle is of the greatest importance, for the auricles are more easily dilated than the ventricles, since their walls are thin.

General muscular hypertrophy of the heart, associated with a heaving and sometimes tumultuous beat is not necessarily associated with any valvular lesion. Possibly it may result from repeated attacks of myocarditis; much more probably it is the outcome of chronic adhesive pericarditis. In marked cases retraction of the ribs and intercostal spaces synchronous with the apex beat is a frequent feature, and indicates extensive bands of adhesion in the pericardium and anterior mediastinum. In some of these cases the hypertrophy seems to displace the apex beat markedly outwards and not at all downwards, as if the adherent bands opposed the cardiac enlargement taking place in the usual downward direction; the apex beat is then felt far out in the fifth space. But commonly, also, the shock of the systolic impulse imparted to the parietes makes any palpation, even of the apex beat, very difficult; a determination of the position of maximum audibility of the first sound is then a valuable help in determining the position of the apex beat. In the absence, however, of such confirmatory signs, and of a history of pericardial friction sounds or fluid, the existence of chronic adhesive pericarditis in a small degree can only be surmised in cases of moderate general muscular hypertrophy.

Whether there is any residual active myocarditis in a given case can only be determined apart from constitutional signs, by the principle indicated above—i.e., that where the abnormal cardiac signs are still changing, the stage of infective activity and tissue-response to infection cannot be said to have closed. Under such conditions the heart requires further observation at rest. Signs of favourable changes are: (*a*) Diminishing rapidity and excitability of the heart beat; (*b*) Diminishing cardiac dullness; (*c*) disappearance of the systolic murmur. Considerable time, moreover, may be needed before these changes are completed. In one case under observation it was five months before an excitable and rapidly beating heart settled down to a constant and deliberate rhythm; during this time the cardiac dullness diminished, and when the child was re-examined a year later, after seven months' living at home in London, the heart appeared normal in every respect. When, however, there is no longer any indication of change in the physical signs, it will probably be safe to allow the child to begin to get up. There is no point in keeping a child in bed because the heart is abnormal merely, but only when the abnormal condition is changing. Nevertheless, the process of getting up and about must be very gently graduated; at first the child should only be allowed to sit up for a quarter of an hour in the day, and the amount of activity is then gradually increased, careful watch being kept for any unfavourable reactions in the physical signs. As a result of rest and gradually promoted convalescence in seaside air for periods varying from four to eight months, seven cases, on re-examination after at least seven months' life in London, show the following results:—

No relapse; normal hearts	5 cases.
Relapse; fresh myocarditis	1 case.
Relapse; aortic regurgitation	1 ,,

2. *Mitral Disease.*—This is, of course, extremely common; 19 out of the 48 cases of chronic carditis had signs of it, while among the more recent cases under treatment at the seaside, 23 out of 44 rheumatic children, whether cardiac or not, showed definite signs of mitral disease. The significance of a systolic bruit is not easy to determine; musical and harsh murmurs are probably endocardial in origin, but apart from two of these in the first or chronic series, systolic bruits have not been considered as evidence of mitral disease.

Where the mitral valve is affected it is much easier than in simple myocarditis to appreciate the presence of a changing process in the lesion, owing to the characteristic nature of the auscultatory sounds. The most important and helpful murmur in mitral disease of rheumatic origin is a diastolic bruit, best heard just internal to the apex of the heart, and often only heard there. This murmur may occur at any time in diastole—just after the second sound, in mid-diastole, or as a presystolic murmur; the significant point about it is that it may disappear altogether if sufficient rest be allowed to the heart; on the other hand, it may persist indefinitely in severe cases—it was present in 10 of the 48 chronic cases examined—or, under more unfavourable conditions, may become converted into the crescendo presystolic murmur of mitral stenosis. Here it may be said that not every presystolic murmur, of course, is indicative of mitral stenosis, using that term in the sense of a cicatricial narrowing of the orifice. The presystolic thrill and murmur of mitral stenosis are always accompanied by a marked hypertrophy of the right ventricle, which can be felt during systole through the epigastrium and diaphragm as a large and hard mass, giving rise to a marked epigastric pulsation. This presystolic murmur is also a permanent murmur, but the presystolic murmur of more recent endocarditis, though it may be accompanied by a thrill, gives way early, under conditions of complete rest, to a mid-diastolic bruit, at which stage the condition may become stationary for a time—or even permanently. But this bruit also tends to change: it then appears earlier in diastole, and is heard just internal to the apex beat as a reduplicated second sound. With still further rest, the reduplication also may disappear and continue absent on the child's being allowed later gradually to get up. The bruit may be called one of mitral obstruction, as opposed to stenosis, and is probably caused by the presence of an active, quiescent, or healed vegetation on the mitral valve, or, as recently suggested by Sir Thomas Horder, to a progressive sclerosing endocarditis from infiltration of the valve-cusps [16]; in any case it is never accompanied by a hypertrophy of the right ventricle, such as occurs in stenosis.

It is most important that this bruit of mitral obstruction be not allowed to grow more marked or even to continue if possible; it is usually accompanied in recent cases by great excitability of the pulse and by cardiac dilatation from myocarditis, so that the indications for rest are two-fold. Without adequate rest, if there is any activity in the cusps of the mitral valve, their tendency will be to become further inflamed—a condition of extreme gravity, for though the myocardium is the essential part of the heart, it is the endocardium which in rheumatic carditis is the most dangerous source of recurring toxicity—largely owing to its direct communication with the blood-stream; at best, under such conditions the cusps will tend ultimately to give rise, by coalescence of their adjoining edges, to the serious clinical condition of mitral stenosis.

The morbid anatomy of endocarditis shows that in severe cases which come to post-mortem examination a greater or less degree of fibrinous deposit is found on the valves; this is followed by œdema, thickening, and deformity; vascularisation also is a frequent occurrence. It is easy to see, then, how mitral stenosis becomes established as a progressive lesion. But while the endocardial changes are as yet presumably slight, there is no reason why, given sufficiently favourable conditions, the lesion should not be cleared up with a minimum of damage, vascularisation, and cicatrix, somewhat as a corneal ulcer clears up. But any analogy to the non-vascular cornea seems to break down in the light of the work done by L. Gross [17] on the blood-supply to the heart valves and its relation to inflammation of the valves. Gross finds that all fœtal valves contain a musculature and vasculature, the natural tendency of which is to regress as age advances; vessels in normal adult valves are hardly ever demonstrable, but the valves of children contain both muscle and vessels. Moreover, all cases of valvular endocarditis show a vasculature in the valves, and in adults the most frequent site of endocarditis is the aortic cusp of the mitral valves, which is the last leaflet to lose its musculature. Thus it seems that in the child, as contrasted with the adult, the tendency to endocarditis is associated with the presence of the remains of the fœtal vasculature, and it is further inherently probable that where there has been inflammation, the regression of the vasculature will be retarded; finally, if there is established a chronic inflammatory condition of the valve, the vascularisation of the valve will tend to become permanent—a condition of affairs which stands in close relation to severe endocarditis occurring later in life.

In any case, effort must be directed to enable the valve to return as nearly as it can to its original condition. And while the physical signs are receding, it is fair to suppose that the lesions are tending to clear up. But it may take as long as six months before a diastolic bruit of mitral obstruction clears up. This happened in one case under observation in 1922, and when this child was re-examined after seven months of life in London, attending an ordinary school, the heart was practically normal, only a very slight degree of residual enlargement of the heart showing that there had ever been any trouble; the auscultatory signs were quite normal. Altogether four such cases were discharged from the seaside after rest in bed for from five to eight months, followed by gradual resumption of activity; on re-examination, after seven months' life in London, two of the children showed approximately normal hearts; one other was normal after continuing to reside at the seaside for two years. The fourth case has still an unchanged systolic murmur, but there has been no relapse and no return of any diastolic bruit. All four of them had had diastolic bruits associated with excitable pulses and cardiac dilatation; they were none of them allowed to get up until some time after the diastolic bruits had completely disappeared (see Cases 19, 22, 23, and 29).

It should be mentioned that three of these four cases had had chorea, and that only one of them has relapsed and been in hospital again—for this symptom only; but this child was only kept there for a fortnight, the functional element being considered predominant; it was interesting to notice that, while at the seaside, this child had a temporary return of all her choreic symptoms, which had been absent for some months, on being visited by a very anxious mother.

It is not, of course, suggested that the above cases are in any way cured; on the contrary, they are all in need of the most regular after-care and observation to forestall relapse; a restful summer country holiday is advised as an important feature of such after-treatment. It is thought, however, that in each case, just as in the myocardial cases a progressive cardiac lesion has, for a time at least, been arrested. Two other children with this mitral bruit who were withdrawn from treatment at the end of three months have both relapsed and had to go to hospital again; the murmur is still persisting in several cases of more severe and complicated heart disease under more prolonged treatment, and it was present in the case of two children that died. Two cases are still under observation, in which a presystolic murmur of mitral obstruction has disappeared in one case and given way in another to a mid-diastolic bruit. One of these two cases has just been withdrawn—from lack of funds; she has, therefore, of necessity to be allowed to get up gradually before undertaking the journey home. The diastolic bruit, cardiac dilatation, and rapid pulse are all in evidence again.

3. *Aortic Disease.*—Whereas mitral regurgitation in children seems never to lead per se to much hypertrophy of the right ventricle, aortic regurgitation is always apparently accompanied by a marked hypertrophic enlargement of the left ventricle, the apex beat having been found in the sixth space with a forcible impulse in every one of the nine cases examined. For some reason, aortic stenosis seems to be a rare complication of rheumatic disease, though it was present in one case examined, with a very definite history of recurring attacks of rheumatism spread over four years. Possibly the earlier regression of the vasculature from the aortic valve cusps may account for the relative infrequency of this severe complication. Aortic lesions, being rarer than myocardial and mitral lesions, are more apt to be complicated by the occurrence of the latter, and are, therefore, probably harder to study in detail. Adults suffering from aortic disease of other than rheumatic origin are frequently able to live active lives, and the mechanical deficiency of the valve need not, therefore, be considered a sign of great gravity. The amount of rest required by each patient will depend upon the evidence of there still being active infection existing in the heart as a whole, as judged by the presence or absence of change in the physical signs, myocardial and endocardial; the diastolic murmur of aortic regurgitation does not seem ever to undergo any favourable modification.

Analysis of Cases.

The following is an analysis of my own 44 cases (33 girls, 11 boys) under treatment at the seaside for rheumatic disease—mostly during the past two years. The average age was 10 years, the lowest age encountered being 6 years. It is important, I think, to say that the children have been very content and happy, even when confined to bed for many months, and this necessary factor has been due entirely to the tactful supervision of the sisters and nursing staff. Only two girls became fretful under treatment and neither did well; such children are best got rid of, partly because under emotional stress they do not make good progress, but also in the interests of the other patients in the wards. It has been found very important to have isolation accommodation for any child with a pyrexial attack, especially when tonsillitis is present.

1. Girl, aged 12; history of chorea two years; heart normal but beat rather irregular; discharged free from symptoms within six weeks. Re-examined after 18 months. Return of chorea. Heart-beat excitable still.

2. Girl, aged 12; history of chorea two months; heart normal but for soft systolic murmur, which soon disappeared. Remained six weeks. Re-examined after 18 months: quite normal.

3. Boy, aged 8; history of chorea nine months; heart normal on admission, but reduplicated second sound at apex developed; this was corrected by rest; he remained six weeks. Re-examined after 18 months: fresh chorea, some cardiac dilatation.

4. Boy, aged 8; chorea for three years, also rheumatic pains; heart normal but for slight irregularity of pulse; remained six weeks. Re-examined after 18 months: fresh chorea, some cardiac dilatation.

5. Girl. aged 13; slight attacks of rheumatism during one year; heart normal; remained six weeks. Re-examined after 18 months: quite normal.

6. Boy, aged 9; chorea eight weeks; heart normal; remained six weeks. Re-examined after 18 months: quite normal.

7. Boy, aged 9; history of chorea; heart normal; remained six weeks. Re-examined after 18 months Chorea still present, heart normal.

8. Girl, aged 9; rheumatic pains three weeks before admission; no present symptoms; remained three months. Re-examined after 18 months. Had had further heart attacks. Heart showed left ventricular enlargement and aortic regurgitation.

9. Boy, aged 7; pain in one hip for eight months; admitted with hitherto undetected heart disease (mitral regurgitation and early stenosis; aortic regurgitation), shortly developed acute tonsillitis, thought to have infected a nurse and four other cases (10, 11, 12, and 13) directly or indirectly. Withdrawn after three weeks.

10.[*] Girl, aged 14; continually repeated rheumatic attacks for two years. Showed pallor, tumultuous and rapid heart-beat with systolic retraction of the chest wall from extensive adherent pericardium; mitral disease; great cardiac hypertrophy; appeared very ill. Great improvement effected during first year in country. Then four recrudescences occurred in April to July, 1923, thought to have followed on exposure to infection from Case 9. Patient again became very pale and ill, and the heart took on the characteristics of auricular fibrillation. She got better under the influence of digitalis, but was shortly afterwards sent back to hospital with a grave prognosis. She has since died. Post mortem: the heart reveals very extensive adherent pericarditis, but no mediastinitis, great thickening of the mitral valve, and a few small recent vegetations on the aortic valve. There was general muscular hypertrophy.

11. Boy, aged 9; no history of rheumatism, but had been in and out of hospitals for chorea for three years. Considerable cardiac dilatation; mitral regurgitation and obstruction (apical diastolic bruit). Chorea got cured with rest and arsenic in five months. Heart condition much improved till reinfected, as is thought, from Case 9, when slight feverish condition with sore throat was followed after a month by long illness—pyrexia for three weeks, return of pallor, and intensification of all heart signs. Is now much better and beginning to get up again; all bruits remain as before.

12. Girl, aged 11; pains in joints 13 weeks, then chorea. Heart normal but for a mitral systolic bruit; an excitable pulse soon quieted down with rest. Then had seven days fever, resulting, as was thought, from reinfection from Case 9. Getting better again now, but mitral obstruction and aortic regurgitation have resulted from this illness (diastolic apical bruit and diastolic basal murmur).

13. Girl, aged 6; rheumatic fever three months before admission; slight chorea on admission; heart normal. Acquired tonsillitis, possibly indirectly from Case 9, after which mid-diastolic bruit at apex appeared; this was abolished after six weeks' rest. Now progressing well.

14. Girl, aged 13; rheumatic pain three months; had had dyspnœa. Heart showed on admission long-established heart disease. Hypertrophy of right and left ventricles; murmurs of mitral regurgitation, mitral stenosis, and aortic regurgitation; epigastric pulsation. Pulse very excitable—not affected by any drug. Kept at rest 11 months, then began to get up little by little. At the end of 18 months some ascites, œdema of feet, albuminuria occurred, soon corrected by short rest and full doses of digitalis. Now doing well again without digitalis. Future very uncertain. Pulse always most rapid and excitable.

15. Girl, aged 10; four times in hospital for chorea and rheumatism since 1919. Altogether five attacks of chorea and many sore throats. R. ventricle hypertrophied; bruit of mitral stenosis. Rest for three months. Now getting up; pulse has come down from 100 to 76. Heart much less excitable and no longer tumultuous at epigastrium.

16. Girl, aged 9; ill off and on for a long time. Heart dilated; presystolic bruit has become converted into mid-diastolic bruit in 14 days. Still at rest. Heart rapid and excitable.

17. Girl, aged 9; mitral regurgitation one year; never any pain or sore throat or chorea. Pulse rather rapid and variable; soft systolic murmur. Convalescent after three months.

---

[*] I am indebted to Dr. Clifford Ellingworth, of the West London Hospital, for kindly sending me the heart of Case 10 to examine post mortem.

18. Girl, aged 13; three attacks in two years; endocarditis and pericarditis; pain in precordium. General hypertrophy of heart; soft systolic murmurs. Pulmonary second accentuated. Excitable pulse is now quiet after two months' rest. Getting up bit by bit.

19. Girl, aged 9; history of rheumatic carditis 11 weeks. Pulse rapid and excitable. Very slight chorea. Mitral regurgitation and obstruction (apical reduplicated second sound). Pallor. After seven months' rest pallor, excitable pulse, and apical reduplicated second sound vanished. Returned home after about a year. Re-examined seven months later, mitral regurgitation only. Pulse quiet, arrest of mitral stenosis.

20. Girl, aged 8; history of slight rheumatism, resulting in endocarditis and pericarditis during 18 weeks before admission. Heart normal except for systolic murmur at apex, which disappeared after ten weeks; was completely at rest for one month. Withdrawn from treatment after ten weeks. Re-examined a year later: had had fresh attack of rheumatic fever, now some dyspnœa and general cardiac hypertrophy, probably from adherent pericardium.

21. Girl, aged 12; chorea one year, often has pains in legs and arms, also sore throat sometimes. Heart normal. Chorea stopped by rest and liq. arsenicalis ♏ vii. t.d.s. Now getting up.

22. Girl, aged 8; chorea ten months. Heart: soft systolic murmur with reduplicated apical second sound (mitral obstruction). Rested for five months, at the end of which reduplicated second sound was gone; chorea disappeared with liq. arsenicalis ♏ iv. t.d.s. Re-examined after 18 months: heart normal, but had had some chorea, considered functional at hospital. Is now quite well.

23. Girl, aged 12; three attacks of rheumatism during two years before admission. Heart dilated, pulse excitable. Soft systolic and reduplicated apical second sound (mitral obstruction). Pale. Rested for seven months. Pulse quieted down after three months, systolic murmur disappeared in six months, and obstruction bruit in seven months. Re-examined after 18 months: heart approximately normal in dimensions, no adventitious signs on auscultation.

24. Girl, aged 12; acute rheumatic fever seven weeks before admission. Pulse excitable; heart very dilated. Soft systolic and well-marked presystolic bruits. Presystolic soon gave place to mid-diastolic bruit, then to reduplicated apical second sound. After two months child began to fret owing to letters from home, and heart signs began to reappear. As she never settled down again she was discharged after four months.

25. Girl, aged 13; rheumatic carditis two months; double mitral bruit. Heart had soft systolic only; remained at seaside four months. Re-examined 18 months later: systolic murmur only present, chorea once again.

26. Girl, aged 14; rheumatism at least five times in five years. Heart-beat very rapid; double mitral and double aortic bruits; marked pallor. Kept at rest, but fretted to be home very much; very emotional. Allowed to get up gently; pyrexia and arthritis began. Was doing no good and was discharged home where she died soon after.

27. Girl, aged 12; history: rheumatic fever seven months before admission for two months; in bed three months, getting up since; now very short of breath. Very ill and pale; heart enormously dilated; soft systolic and diastolic apical bruits. Nodules over elbows and knee; erythema iris developed on the back; pyrexia frequently; kept at rest, but steadily deteriorated and died in less than six weeks.

28. Girl, aged 12; cardiac trouble for three years since acute rheumatism. Double mitral bruit present. Was kept at rest, but was withdrawn from seaside; died some weeks or months later.

29. Girl, aged 9; contracted subacute rheumatism at seaside; quickly followed by chorea and soft mitral systolic and mitral diastolic bruits with some cardiac dilatation. Kept at rest for four and a half months; all symptoms and signs completely cleared up, and after eight months she was allowed to live a normal quiet life. After three years the heart's condition remains normal and there has been no relapse at any time.

30. Girl, aged 11; chorea two months. Appeared normal in every way and was given moderate rest for two months, then discharged. Readmitted much worse after three months; bad chorea present and cardiac dilatation and soft systolic murmur at apex. All symptoms reduced by rest and Fowler's solution in three months. Re-examined after six months: normal in every respect.

31. Boy, aged 8; free from chorea one month after first attack. Bruits: soft mitral systolic and mitral diastolic. The latter disappeared with three weeks' complete rest. Withdrawn from treatment.

32. Girl, aged 14; rheumatic illness five or six times in two years. Heart: very rapid and excitable beat; systolic and presystolic murmurs at apex. Also aortic diastolic with enlarged left ventricle. Presystolic bruit was accompanied by a thrill, but with complete rest gave way to reduplicated apical second sound in three weeks, which disappeared in another five weeks. Shortly afterwards child was withdrawn from treatment and then discharged after being allowed to get up; showed all the original cardiac signs. Duration of treatment under three months.

33. Girl, aged 11; heart trouble for two years, rheumatic endocarditis. Generalised cardiac hypertrophy, probably from chronic adhesive pericarditis. Mitral systolic and mitral diastolic murmurs. Pulse very excitable. Kept at rest, mitral diastolic bruit was abolished in two months, but other signs persisted. Recently withdrawn from treatment. Prognosis considered grave.

34. Girl, aged 13; rheumatism and chorea six months. Heart normal, but for soft systolic, which disappeared in six weeks. Discharged shortly afterwards.

35. Boy, aged 8; heart trouble for six months. Heart rather dilated, and occasionally a reduplicated apical second sound heard. Tendency noted for heart to become markedly dilated on any slight additional exertion. Gradually became convalescent during six months, and on re-examination 18 months from first admission was normal in every way.

36. Boy, aged 9; chorea for four months, mitral diastolic murmur very faintly audible at times. Withdrawn.

37. Girl, aged 9; tuberculous child discovered to have very rapid and excitable heart with pulsation in the neck. No rheumatic history, but thought to be rheumatic. Pulse settled down to deliberate rhythm in five months. Re-examined seven months later: perfectly normal.

38. Girl, aged 9; chorea one year, rheumatism once recently. Some cardiac dilatation, soft systolic murmur; pallor. Withdrawn after two and a half months. Re-examined after six months: had had a fresh attack of rheumatism with chorea. Heart condition much as before.

39. Girl, aged 9; had "growing pains," then chorea six weeks before admission. Heart dilated with soft systolic murmur. Heart normal in ten weeks' time; kept in bed for a month. Re-examined after six months: normal.

40. Girl, aged 10; subacute rheumatism two months. Heart normal; discharged after six weeks. Will be re-examined next year, if possible.

41. Boy, aged 8; rheumatic pains three weeks before admission. Heart perfectly normal. Stayed for three months; normal on discharge. Re-examined 18 months later: had had bad relapse with resulting aortic disease and great left heart hypertrophy.

42. Girl, aged 11; rheumatism 12 weeks. Heart showed rapid action, musical mitral systolic, and reduplicated second sound at apex. Considerable dilatation. Withdrawn from treatment after three months. In Carshalton hospital 18 months later.

43. Girl, aged 13; pains in legs three to four years before admission. Has been attending hospital ever since on and off. Pains again this year. Heart shows a soft systolic murmur only. Infection would seem to be of a very low virulence if active at all. Is now getting up after a month's rest.

44. Boy, aged 13; acute rheumatism, following upon tonsillectomy; operation was performed in consequence of recurrent attacks of tonsillitis. All the joints returned to normal except one ankle, which became pyæmic and had to be incised and is now ankylosed. The heart is normal in dimensions but shows a soft systolic murmur; he has also had a considerable amount of chorea, which was abolished by rest and Fowler's solution. This case is of special interest as showing characteristics of both metastatic arthritis and of rheumatic disease. He is having an arthroplasty performed upon the ankle this year, six months after the incision over the joint was completely healed.

Conclusions.

1. The absence of a working knowledge of the bacteriology underlying rheumatic disease is an important factor in delaying the recognition of the great need that exists of controlling a disease which is of very widespread incidence and which has far-reaching effects upon the health of the community. At the same time, the absence of institutions where patients might be under collective observation prevents there being an opportunity for organised research upon the causation of the disease. Here there is indeed a vicious circle.

2. While no doubt family predisposition, bad housing, and damp are important factors in spreading the disease, there is evidence that rheumatic disease may be infectious, in which case the isolation of patients suffering from the rheumatic state would be desirable.

3. In rheumatic children sent away to the country for a period of rest, it has been found that the shorter their stay in the country, the more frequently do they relapse, and vice versâ ; this, moreover, appears to be the case independently, to some extent, of whether they have heart disease or not. The longer the stay, therefore, the better the prognosis is likely to become.

4. Tonsillectomy is an important factor in controlling the recurrence of acute rheumatism and rheumatic pains ; it is less effective in chorea (W. St. Lawrence).

5. It would be in the end an economy of time and money as well as of health if every child who had shown any manifestation of rheumatic disease were sent into the country for a long term of rest or quiet life, just as tuberculous cases are sent away.

6. Many cases could only be arrested in an early stage if the disease were made notifiable ; notification would also enable contacts to be inquired into and examined—an important point in view of the insidious onset of the disease in many cases, and of its common incidence in members of the same family.

7. Cases require complete rest in bed so long as there is any indication that there is active disease, as would be shown by (*a*) constitutional signs and symptoms ; (*b*) progressive changes in the physical signs manifested by the heart ; even favourable changes are to be taken as evidence that an active infective phase has not entirely been closed.

8. Chorea is a complicating constitutional symptom of rheumatism, though often the first that comes under the parents' notice. Given, however, a long-time outlook in the prognosis and treatment of rheumatic disease as a whole, this symptom, like the other constitutional symptoms—e.g., joint pains, anæmia, and pyrexia—will probably yield to treatment. In chorea, however, a functional element is often predominant ; consequently the intensity of the movements and emotions is then no close measure of the extent of the active rheumatic infection, and in this way chorea differs from the other constitutional symptoms. In such cases a discriminating emotional restraint is of the greatest importance.

9. In the diet, milk is the most important ingredient, and where there are any active constitutional symptoms—e.g., pyrexia, arthritis, and rapid pulse, a milky diet or even milk alone should be the only food given. Such a diet has an important effect in reducing the temperature, as was pointed out to me recently by Dr. R. G. Hicks, of Ramsgate.

10. Drugs are most important as adjuncts to a scheme of long-time treatment ; their danger consists in their being allowed to replace it. The following may especially be mentioned :—

(*a*) *Salicylate of Soda.*—Full doses are given in cases of relapse with pyrexia, especially when pain is present. Double doses of the bicarbonate of soda are always given at the same time.

(*b*) *Arsenic.*—Fowler's solution usually completes the reduction, by rest in bed, of chorea, if given time enough. The dose is increased week by week by ♏ i., starting from ♏ ii. and progressing up to ♏ vi. or even ♏ ix. t.d.s. Symptoms of intolerance have not been met with, and the choreic symptoms disappear at a certain level of dosage ; the dose is then kept constant for two or three weeks, after which it is similarly lowered by ♏ i. or ♏ ii. every week, until the drug has been left off. In cases of intolerance to the oral administration of arsenic, cacodylate of soda given hypodermically would probably be useful.

(*c*) *Digitalis.*—Moderate or full doses of the tincture are useful in some cases of recent or active myocarditis. One effect of the rheumatic poison upon the myocardium, unlike that of typhoid fever, is excitation, and the administration of digitalis probably gives rest to the heart muscle by showing the rate of the heart-beat. In many nervous, excitable children, however, it has very little effect.

(*d*) *Iron and Hæmoglobin.*—These are indicated by anæmia persisting during the long convalescent stage.

(*e*) *Opium.*—This drug has not much use in early heart disease ; it is of use rather in cases of great excitability of the heart associated with pericardial adhesion, and is usually given in company with digitalis.

11. In rheumatic disease generally it appears that a much longer outlook has to be taken of the time-element necessary to effect a cure. A length of time, approximating even to that required for the cure of tuberculous cases, would not be unreasonable in view of the comparative destructiveness of the disease. Under the present conditions available for poor folk any prognosis other than a grave one is unreasonable, while even among the well-to-do, cases may be seen of the most fatal and crippling type, because sufficient rest has not been persisted in at the onset. The fact that in some cases the child does not feel ill at all until the heart has suffered irretrievable damage points to the absolute need for constant supervision of the heart in the early stages of the disease, and such constant supervision cannot be carried on effectively under the general conditions obtaining at present ; similarly, the carrying out of adequate after-care in cases discharged from the hospitals is at present exceedingly difficult to manage. Early and prolonged treatment and regular and prolonged after-care are the most important requirements in the management of acute rheumatism to-day.

SPINAL ANÆSTHESIA AND ITS DRAWBACKS.

BY BERNARD DESPLAS,
CHIRURGIEN DES HÔPITAUX DE PARIS.

SINCE entering into everyday use under the powerful influence, first of Tuffier and afterwards of Chaput, spinal anæsthesia has been amply discussed, and since the war the question has been permanently to the fore ; its undoubted and numerous advantages have been vaunted and its disadvantages have been emphasised—often with considerable force, for it has been held responsible for accidents of considerable gravity. My chief, Paul Riche, initiated me into the practice of spinal anæsthesia by stovaine in 1909, and I have since then personally carried out some 2000 spinal anæsthesias, which number perhaps entitles me to a personal opinion borne out by facts.

I do not wish to deal here with the indications, technique, or advantages of this method. Wishing to define its disadvantages, I observed with the greatest care the cases of 260 patients rachianæsthetised and operated upon by myself at Prof. Gosset's private clinic—not only at the time of the operation itself but also during the post-operative period—I made notes of the anæsthetic used, the incidents occurring during anæsthesia and the days following, and, finally, after a considerable length of time had elapsed ; it is the result of these observations which I wish to summarise here.

Technique.

There are, of course, two distinct forms of spinal anæsthesia : (1) Spinal anæsthesia limited to subumbilical operations, and (2) generalised spinal anæsthesia. The latter may be attained by two methods, one being Jonesco's, consisting in administering the anæsthetic at different heights of the spine by means of spinal punctures, the height of which depends on the extent of the anæsthesia desired ;

and the second that of Le Filliatre, Delmas, and others, consisting in the evacuation of cerebro-spinal fluid, the quantity of which is in direct ratio to the extent of the anæsthesia desired, and varies from 20 to 25, 30 and 35 c.cm. of fluid. In this manner, after the injection of the anæsthetic, insensibility may be obtained as far as the trigeminal region.

I have carried out spinal anæsthesia by the Le Filliatre method in cases of operations above the level of the umbilicus, without obtaining results of remarkable constancy or quality, whereas I have almost always noticed (in one case out of every two) that the patients bore badly these large withdrawals of cerebro-spinal fluid and the dissemination of the anæsthetic as far as the highest regions of the cerebro-spinal axis. I have given up spinal anæsthesia entirely for all operations not limited to the sub-umbilical segment of the body.

I usually perform the lumbar puncture between the third and fourth lumbar vertebra, withdrawing 10 c.cm. of cerebro-spinal fluid and, using fine needles (Tuffier's), inject 5 cg. of a 10 per cent. solution of stovaine-billon. I have used other anæsthetics in a number of cases, but have not thereby found any advantage, and have always reverted to stovaine which, in the course of some 2000 cases, has never given serious trouble, and has so far not been the cause of death or permanent or definite injury.

Statistics of Cases Treated.

I have followed up 270 cases of spinal anæsthesia, the most recent dating from December, 1922, and have made a point of noting scrupulously every incident in their history. The cases were as follows:—

214 anæsthetised with stovaine, 10 per cent. solution.
5 ,, ,, scurocaine.
18 ,, ,, syncaine.
3 ,, ,, novocaine Merck.
30 ,, ,, stovaine caffeine according to a formula similar to that of Jonesco.

Of these 270 cases of anæsthesia, only seven were for sub-umbilical operations. I was completely unsuccessful in 10 cases which necessitated a second anæsthesia; all observations were conclusive from that point of view, the patients being nervous and uneasy. In five cases there was an insufficient flow of the cerebro-spinal fluid at the time of the puncture. Out of these 10 cases there were:—

7 anæsthetised with stovaine.
2 ,, ,, syncaine.
1 ,, ,, novocaine.

In one case where syncaine did not take effect I administered stovaine a second time, obtaining an excellent result. In 3·7 per cent. of the cases no anæsthesia whatsoever was obtained, either objectively or subjectively, and a second administration was thus required. In eight cases (stovaine) the anæsthesia was adequate and enabled the operation to be carried out, but the patients noticed a sensation of discomfort and pain, especially at the moment of the opening of the peritoneum and during the abdominal manipulations, internal traction, separation of adhesions, &c. In all the other cases, 242 out of 260, anæsthesia was perfect and lasted from one hour to one hour and a quarter.

Discussion of Failures.

How can these failures, some complete, some partial, be explained? They might be attributed to a bad quality of the anæsthetic, which is unlikely, as the ampoules containing it are prepared in great quantities. The product may be acted upon by the glass of the ampoule; this explanation has value, because hard glass unaffected by water at the temperature of the autoclave is at present difficult to obtain industrially.

It may also be considered that the anæsthetic has not been carried entirely into the interior of the theca. The needle terminates in a fairly long bevel, and if the penetration into the subarachnoid space has been incomplete—i.e., if the dura mater is astride the bevel—the anæsthetic solution may be distributed either entirely or partly around the dura mater, which explains the insufficiency or absence of anæsthesia. Finally, the possibility of compartments existing in the subarachnoid space must not be lost sight of, because in cases of insufficient anæsthesia, and even when the anæsthesia is perfect, an absence of motor paralysis is noticeable, as if the anterior roots had not been touched by the anæsthetic used. Then there are patients whose psychological condition prohibits the use of spinal anæsthesia.

During the period of anæsthesia I have noticed cyanosis three times, and 40 cases of vomiting, sometimes accompanied by pallor with sweating and dizziness. The three cases of cyanosis recorded were observed during extensive anæsthesia administered for operations above the level of the umbilicus—viz., three cases of cholecystectomy. The anæsthetic used was stovaine, with a withdrawal of 20 c.cm. of cerebro-spinal fluid. In 40 cases of vomiting the anæsthetics were distributed as follows: 30 stovaine (pure), two scurocaine, eight syncaine. In the above record stovaine caused vomiting during operation 30 times out of 214 cases—i.e., in 14 per cent. of the cases recorded.

Post-Operative Complications.

The study of the post-operative incidents is no less interesting.

Vomiting.—Of 29 cases, in 23 the vomiting was of short duration. In 20 of the latter the symptom was recorded in the first 12 hours after the operation; in the remaining three cases there was vomiting during 24 or 48 hours, accompanied in these cases by headaches, torpor, slight photophobia, and occurring without any cause, or as the result of a change in position. In six cases the vomiting lasted over six days, accompanied, moreover, by severe cephalalgia and an undeniable state of torpor with saburral tongue.

Cephalalgia.—Of 37 cases, in 23 cephalalgia occurred during two or three days, commencing 24 or 48 hours after the operation and accompanied, in three cases, by vomiting of a cerebral type. These cases of transitory cephalalgia could be overcome by aspirin and absolute rest without any other treatment. The anæsthetic used was in 16 cases stovaine (pure), in two scurocaine, in five syncaine. In 14 cases the cephalalgia was more intense and lasting. It is interesting to note that these prolonged cases of intense cephalalgia occur either immediately after the operation, lasting four or six days, or several days after the operation—i.e., real retarded cephalalgia, lasting variable periods. The cephalalgia usually occurred alone; in six cases it was accompanied by vomiting.

Of the remaining 14 cases the anæsthetic used was stovaine in 12, scurocaine in one, and syncaine in one. Summarising the cases of cephalalgia, then, we have: In 240 cases of spinal anæsthesia, 37 (or 16 per cent.) had cephalalgia; in 214 of these 240 cases stovaine was administered, and 28 of the 214 (or 13 per cent.) had cephalalgia; in the remaining 26 of the 214, nine cases (or 34 per cent.) had cephalalgia, three of these nine having had scurocaine administered, and six syncaine.

The cephalalgia is often aggravating, always troublesome, and difficult to account for, many hypotheses having been advanced in the matter. It is due to meningeal irritation; it was once thought that it was consecutive to phenomena due to hyperpressure, but cases in which a slow pulse-rate is recorded are altogether exceptional. I noticed this in one case only (spinal anæsthesia by stovaine). I performed an evacuating lumbar puncture, which did not modify the cephalalgia. It has also been attributed to the escape of cerebro-spinal fluid through the breach in the rigid dura mater formed by the puncturing needle. Whilst emphasising the power of secretion of the choroid plexuses, which tends to prevent this loss, it should be noted that the use of the finest of needles and all the steps taken to prevent such oozing, ventral decubitus in particular, are without result. Finally, it is a matter of experience that cephalalgia occurs in series, without its being known exactly why and without its being possible to attribute it more to the one or the other anæsthetic used. In any case it constitutes the most important complication of spinal anæsthesia.

Other Complications.—I observed, beyond these complications, one case of subicterus in an operation for hernia (stovaine); one case of shingles on the second day (stovaine), combined with a cerebral syndrome characterised by cephalalgia and vomiting; two cases of strabismus through transitory paralysis of the external ocular motor. These two cases were observed after spinal anæsthesia by stovaine; strabismus was combined with a syndrome of meningeal irritation, consisting of cephalalgia and vomiting. The patients were non-syphilitic. In both cases the strabismus was progressive. It occurred on the sixth day, diplopia lasted five to seven days, and finally subsided completely.

In order to give a complete account of my observations, I must mention that I recorded 12 cases of pulmonary congestion, of which 10 occurred after spinal anæsthesia by stovaine, which proves that spinal anæsthesia is no protection against post-operative pulmonary complications, as has been erroneously thought. Such are the only disorders recorded. I have not recorded any cases of paralysis or paresis of the lower limbs, or of sphincteral disorders, such as have been brought to notice. In my 2000 cases of spinal anæsthesia there has not been a single case of fatal complication.

I have carried out spinal anæsthesia in 30 cases with the stovaine-caffeine mixture similar to Jonesco's and corresponding to the following formula: Stovaine 0·06 g., caffeine 0·50 g., sodium benzoate 0·50 g., water q.s. for 2 c.cm., in sterilised ampoules.

Patients who were rachianæsthetised in this manner did not undergo any facial alteration; the face retained its normal colour, or even became slightly coloured. The pulse was not modified. In five cases out of 30 I observed vomiting during the operation. The most remarkable thing is that the patients had no post-operative inconvenience, and cephalalgia was not recorded in any of the cases injected with the above-mentioned stovaine-caffeine mixture. It would appear, therefore, that the addition of caffeine to stovaine not only does not modify the anæsthetic properties of this product, but, by practically completely obviating cephalalgia and reducing vomiting considerably, improves to a great extent the after-effects of the anæsthesia.

The superiority of this mixture of stovaine and caffeine has already been pointed out by Jonesco, and also by Carlos E. Roe, of Madrid, in *Medicina Ibera* of Nov. 11th, 1922. The latter has performed 5005 spinal anæsthesias. He uses stovaine in doses of 0·07 g., and has had only one fatal case in which for an operation of the thorax he injected 0·12 g. of stovaine by the Le Filliatre method. Since 1921 he has used the following mixture: Stovaine 0·07 g., caffeine 0·20 g., water 1 c.cm.

The post-anæsthetic sequelæ emphasised by writers were not noticed by Roe, who considers that the interpretation of these symptoms is pure imagination. In 1921[1] René, Bloch and Hertz published five observations of serious cases of syncope successfully treated by intraspinal injections of caffeine. These cases of syncope were consecutive to generalised anæsthesia administered by the Le Filliatre-Delmas method with syncaine or scurocaine as anæsthetic agent. Recently[2] there appeared eight further observations of serious cases of syncope, following spinal anæsthesia administered in every case for operations on the sub-umbilical segment of the body. The different anæsthetics used were: Novocaine, five cases; syncaine, two; scurocaine, one case. Two of these cases of syncope were fatal; all eight were treated with intraspinal injections of caffeine, and six cures resulted.

One cannot help noticing that the serious complications recorded requiring "heroic medication" are not consecutive to spinal anæsthesia administered with stovaine. Personally, in some 2000 cases, I have never encountered accidents of such considerable gravity, nor have I ever found myself compelled to imitate Bloch and Hertz in administering a secondary injection of caffeine into the subarachnoid space. The observations of different origin which have been published by these authors show that spinal anæsthesia was practised on the lower segments of the body. No attempt was made to obtain generalised anæsthesia, yet there were eight cases of serious syncope, the anæsthetic used being novocaine or one of its derivatives; thus I cannot agree with Bloch and Hertz that this product is non-toxic. Bloch and Hertz point out an interesting fact—namely, that the mixture of novocaine-caffeine has imperfect anæsthetic properties; this brings it into contrast with the remarkable efficacy of the stovaine-caffeine mixture, as personally experienced by myself, by Jonesco, and by Roe. Bloch and Hertz conclude that the reduction of the anæsthetic properties of novocaine through the addition of caffeine proves the lesser toxicity of the latter. This conclusion is difficult to comprehend. The fact would go to prove that the anæsthetic value of novocaine is less, but this is not new, and the descending hierarchy of the anæsthetic value of cocaine, of stovaine, and of novocaine has been known for a very long time.

The interesting researches of Bloch and Hertz into intraspinal injection of caffeine to try and arrest serious syncope—which would appear to be fairly frequent, and which was first heard of in 1921, when spinal anæsthesia had been known for 25 years—I have had the privilege of persuading surgeons in favour of this method to associate caffeine with the anæsthetic, an attempt similar to that made a long time ago when the strychnine-stovaine mixture was being used.

Summary.

In some 2000 cases of spinal anæsthesia by stovaine I have never experienced a fatal accident, nor have I had to resort to the "heroic medication" of René, Bloch and Hertz, because I have never met with syncope similar to that described by them. I have studied all the immediate and consecutive disturbances in 260 cases of spinal anæsthesia: cephalalgia, vomiting, strabismus, &c., of which I have already given details. In 30 cases of spinal anæsthesia by stovaine-caffeine I met with no complications. This brings home to me the superiority of this mixture, provided that it be used for sub-umbilical operations according to the technique laid down by Tuffier and Chaput, which is the only one justifying the statement that spinal anæsthesia is the ideal anæsthesia for the single-handed practitioner. Up to July 1st I carried out 90 operations of spinal anæsthesia with the stovaine-caffeine mixture, and always met with the same favourable results. I no longer notice the syndrome of anguish, pallor, sweating, and vomiting during the anæsthesia. In some cases there was isolated vomiting, but in all the patient looked reposed and showed normal facial colouring. No headache or post-operative vomiting was induced. In some cases the duration of the anæsthesia, which attains and exceeds 50 minutes with stovaine, is slightly shortened.

Note.—Experience has proven that it would be advantageous to diminish the dose of caffeine. I have noticed, in fact, in one case a prolonged retention of urine not remarked till then in my observations. Jonesco has drawn similar conclusions. The dose of caffeine to be used should not exceed 0·15 g.

THE TREATMENT OF RHINO-LARYNGOLOGICAL TUBERCULOSIS BY FINSEN LIGHT BATHS, AND RESULTS.[*]

BY DR. OVE STRANDBERG.

From the Finsen Medical Light Institute (Ear, Nose, and Throat Department), Copenhagen.

THE treatment of rhino-laryngological tuberculosis by means of the Finsen light is not entirely new; for as early as nine years ago I published the first few results obtained after treatment of tuberculosis of the larynx by the Finsen light; since then my number of cases has greatly increased and the treatment has been thoroughly tested.

The Method.

The Finsen bath consists mainly of an electrical carbon arc light which is supplied in two sizes, a small one and one somewhat larger. The small one is used for the treatment of more serious cases, who cannot bear to sit up—for instance, patients with tuberculosis of the larynx or patients recently operated on for tuberculosis of the ear. It consists of a system of three electric carbon arc lamps, which are connected either in parallel or in series, the latter, however, only when using a current of 220 volts which will then require a series resistance of 55 volts. The lamps are suspended from the ceiling and have check-rods in a perpendicular plane to prevent the lamps from rotary movement. The lamps must be capable of a perpendicular movement of one metre so that in the end-positions the distance of the light arc from the floor is 75 cm. and 1·75, but these measurements are naturally subject to alteration according to the height of the patient's couch. Two patients, each on his own couch, can be treated simultaneously by this type of Finsen bath. The couch must be as close to the light as possible. The lamps use 20 amperes and 55 volts each. The distance between the light arcs is 550 mm.

With regard to the large Finsen bath, six to eight patients can be treated at the same time, sitting round two large electric carbon arc lamps, each of 75 amperes and 55 volts. The distance between the light arcs of the two lamps is 600 mm. The carbon-electrodes of the lamps are situated perpendicular to each other, the positive being fitted uppermost, because if direct current is used a crater will be formed in the positive electrode, and from this crater the greater part of the effective rays is radiated. With alternating current, on the contrary, the light-cone is emitted from the upper and the lower carbon-electrode alternately, and hence, so much effective chemical light is lost that alternating current cannot be used, without first being converted into direct current. No glass or other covering round the light should be used, as the chemical rays would then be absorbed. The lamps must burn with a clear, steady light, and the carbon-electrodes must not be allowed to glow or to soot up. It is evident that the large lamps generate a larger amount of chemical light than the small ones, but this difference is neutralised by the fact that the patients cannot sit as close to the large lamps as they can lie near to the small ones, because the latter give off less heat than the large ones, and it is of importance that it should be possible to place the patients closer to the light of the small lamps, because the intensity of the light decreases with the square of the distance. On account of the strong light the faces and the eyes of the patients are protected by a paper shade, but otherwise they are completely naked. They must be placed as near to the light as they can bear the heat, and they must turn round occasionally in order that the light may be equally distributed all over the body. When using the large lamps of 75 amperes, a room with a cubic capacity of 90 to 100 m. and with a floor area of 5 by 4·8 metres will be necessary. With the three small lamps, a cubic capacity of 75 to 80 m. and a floor area of 5·5 by 3·5 metres will be sufficient.

The Indications.

Patients with tuberculosis of the larynx or those who are seriously ill or feverish, lie in the Finsen bath the first few days from 10 to 15 minutes, slowly increasing up to the full dose of two and a half hours every alternate day. When they are able to sit up, they may begin with the large lamps, taking a shorter bath the first few times, but they may, of course, continue with the small lamps if more convenient. Patients with other illnesses—for instance, lupus vulgaris, where the state of health in general is good, can well begin with 30 to 45 minutes with the large lamps. After the Finsen bath a tepid shower-bath is always given and the out-patients go home to their work.

In order to be able to treat as many patients as possible we only give a Finsen bath every alternate day, but otherwise I think it is of little importance whether you give a bath every day or only every other day. After the first baths you will find on the body an erythema of varying strength, ranging from an intense blush to the formation of vesicles. In a short time the patients will be brown pigmented, as if sunburnt, and from then onwards will feel no further inconvenience from the Finsen bath; on the contrary, they will find it delightful in every way. It might be expected that patients who walk, during the cold season of the year, straight from a Finsen bath to their work would be more disposed to colds, but my observations would seem to show the contrary.

Contra-indications are shown only in certain heart and kidney troubles—i.e., provided that the latter are not of tuberculous origin. But I am not afraid to treat out-patients also, and even when they have a temperature of 100·4° or 100·8° F. before taking the bath. I have shown, further, that the Finsen bath, even if uncombined with any other treatment, is an effective cure for rhino-laryngological lupus vulgaris and tuberculosis of the larynx; but if you combine the Finsen bath with some other treatment, many of the patients will get well more quickly. Therefore, when treating lupus vulgaris, I always combine the Finsen bath with surgical treatment or electrocoagulation simultaneously. I also do this in many cases of tuberculosis of the larynx.

Heiberg and I have demonstrated—also by histological examination—that the Finsen baths are a thoroughly effective cure for tuberculosis of the nasal mucous membrane, even when uncombined with any other treatment. We have examined the inferior turbinals during various phases of the treatment in a number of cases, and have shown that this treatment exhibited a definite cure. The question of exactly why the Finsen bath has this beneficial effect has not yet been solved.

The Results.

I should like now to mention the results of this treatment when used in lupus vulgaris of the mucous membrane of the nose, mouth, throat and larynx, and in order to do so I will consider the patients who came to my department as new patients during the years 1913 to 1921.

I have treated tuberculosis of the middle ear and the temporal bone with excellent results too, but in view of the brief time I have at my disposal, I will not touch upon them here, but content myself with mentioning the results obtained in tuberculosis proper of the larynx by which term I do not imply the ordinary laryngitis, with some reddening of vocal cords, which is so often found and frequently disappears spontaneously in patients with tuberculosis of the lungs who cough much, but by which I mean the infiltrative or ulcerative affection of the larynx which occurs among patients with tuberculosis of the lungs.

Here we have in all 100 patients, all with aggravated affections of the larynx.

Recurrence: 3.

Still under treatment, 2. Re-cured and without recurrence in one year, 1.

It will be seen that 97 were hoarse and many of them completely aphonic before treatment, yet 78 patients regained their voice full and clear; in 15 cases the voice was improved, while in 4 patients only did the voice remain unchanged even after treatment; 37 patients had pain and difficulty in swallowing before treatment, while after treatment 32 were entirely free from these troubles, 3 were improved, and only 2 patients remained unchanged. I may add that pain and difficulty in swallowing frequently passes off very soon. It is noticeable that the only two patients who showed any hæmoptysis had this symptom also before treatment. None of the other patients, however, exhibited any hæmoptysis at all during treatment.

With regard to the 77 patients who were treated as out-patients it must be pointed out that none of them could obtain any kind of sanatorium treatment, and as they lived in poor—and frequently, because of their illness, very poor—homes, they had no money to spend on any kind of special food, and the majority were obliged to work, as best they could, in order to earn sufficient money to support their homes, and this even during the first period of treatment, when they were often very ill indeed. When they had been treated for some time the majority of the patients were able to work much as before their illness. The 10 patients, who are still under treatment, have all improved, and out of the 37 lapsed patients 19 had improved, in some cases so much that they were able either to be admitted to a sanatorium or they felt so well that they would not spend more time on treatment. The words "unchanged" or "aggravated" mean *materially* unchanged or aggravated, while, as will be seen from the table, nearly all the patients were relieved of their pain and difficulty in swallowing. During the treatment 28 out of 53 increased in weight, some patients only a pound or two, but others as much as 30 lb.

The number of treatments with the light bath averaged about 86. Fifty-three per cent. of cures of tuberculosis of the larynx is a very large percentage, larger than that of any other treatment up to date. But this treatment has later been thoroughly tested in other hospitals also; in the Oresunds Hospital for Tuberculosis at Copenhagen Blegvad cured some 30 per cent .of the 110 in-patients. Affections of the larynx which I have treated were often in a very advanced stage. No doubt the percentage of cures might be greatly increased in patients with less advanced lesions and treated at an earlier stage.

A CASE OF A LARGE PHARYNGEAL DIVERTICULUM

CURED BY OPERATION IN TWO STAGES.

BY IVOR BACK, M.B., B.C. CAMB., F.R.C.S. ENG.,
SURGEON TO ST. GEORGE'S HOSPITAL; SURGEON AND PROCTOLOGIST TO THE GROSVENOR HOSPITAL FOR WOMEN;
AND
LIONEL COLLEDGE, M.B., B.C. CAMB., F.R.C.S. ENG.,
SURGEON TO THE EAR AND THROAT DEPARTMENT, ST. GEORGE'S HOSPITAL; SURGEON TO THE THROAT HOSPITAL, GOLDEN SQUARE.

THE following case is recorded owing to its uncommon character. The patient, a cab-driver, aged 54, was admitted to St. George's Hospital on Sept. 21st, 1922, complaining that he "couldn't keep his food down." He had begun to notice this two years previously. At first small amounts were regurgitated immediately after meals and at rare intervals. The amounts had gradually become larger and the intervals shorter. During the two years he had lost two stone in weight, but had remained at work up to the time of admission.

Condition on Admission.—He was thin and weighed only 8 stone, but his general appearance was good and his appetite was not impaired. After each meal he was observed to cough and bring up mouthfuls of frothy mucus mixed with particles of food. The cough caused him some distress and persisted for about an hour, when a large amount of food was suddenly regurgitated. The average amount was 28 ounces. He said that he often brought up something he had eaten two or three days before. Examination disclosed a soft enlargement with ill-defined outlines in the posterior triangle of the neck on the left side. Skiagrams corroborated the diagnosis of pharyngeal pouch. Fig. 1 shows the characteristic rounded outline of the pouch, descending well into the thoracic inlet. Examination with the screen showed that the bismuth first entered the pouch in driblets and continued to do so until the pouch was filled and its rounded outline complete; all the bismuth taken subsequently passed down the œsophagus direct.

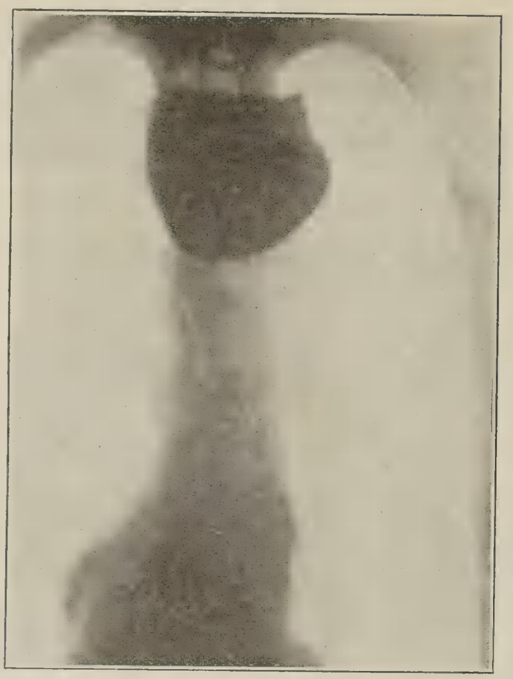
It was decided to operate in two stages. For three days previously the pouch was washed out after each meal with saline lotion introduced through a Jacques catheter. It was quite easy to pass the catheter into the pouch and the fundus appeared to be reached at a distance of 12 inches from the incisor teeth.

Operation.—The first stage of the operation took place on Oct. 9th, 1922. An incision 3½ inches long was made over and parallel to the internal border of the left sterno-mastoid and gradually deepened. The carotid sheath was drawn outwards and the thyroid and trachea gently displaced inwards. The inferior thyroid artery was divided between ligatures. The pouch was brought into view and could be seen to take origin posteriorly, as in all such cases, near the junction of the pharynx and œsophagus. The fundus was gently freed with the finger and brought out into the wound. It was elevated until the internal opening looked downwards and was fixed in that position with catgut sutures to the fascia of the neck. The wound was closed and the pouch left protruding from its upper extremity. At the time of the operation the pouch was 4 inches long, but it rapidly shrank and became quite firm, rather resembling a soft uterine polypus. Fig. 2 shows the appearance of the pouch one week after the first operation. On the afternoon of the day of the first operation the patient could swallow without difficulty or distress and was naturally delighted.

The second stage of the operation took place on Oct. 30th. The pouch was cut off half an inch from the skin level. The fibrous and mucous layers were easily recognised and separated from each other until it was possible to put a couple of purse-string sutures round the mucous layer and invaginate it. The opening in the fibrous layer was closed with a continuous suture. The skin edges were slightly raised without separating the adhesions round the neck of the pouch and brought together. The patient was discharged from the hospital three weeks later with the wound firmly healed.

On Feb. 28th, 1923, the patient reported for inspection. He had recovered the two stone which he had lost, had been at work continuously since his discharge, and described himself as entirely free from any signs of his former trouble. Fig. 3 shows the man's present condition and the wound in the neck completely healed.

FIG. 1.

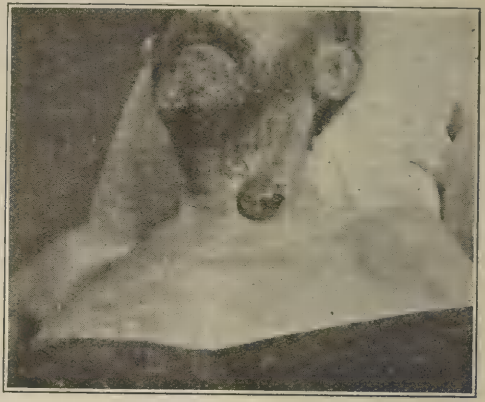


Showing rounded outline of pouch filled with bismuth, and bismuth passing down the œsophagus. (For the photographs we are indebted to Mr. C. P. Miller, of St. George's Hospital.)

Remarks.

Although such cases as this are not so rare as Butlin supposed when he first reported one in 1893,[1] yet they are sufficiently uncommon to justify the record of a single case, in which the pouch was of such great size as to hold nearly a pint and a half. In the earlier operations performed in one stage, there was commonly leakage from opening the pouch and grave risk to the patient from mediastinitis. To avoid this risk some operators recommended invagination of the pouch into the pharynx or œsophagus or fixation upwards to the side of the pharynx without opening it. In such cases temporary success was liable to be followed by recurrence of the symptoms, if the pouch regained its original position. The method adopted in this case secures a radical cure by excision of the pouch, whilst at the same time the risk of mediastinitis is reduced to a minimum, since the sac is not opened until its neck has become firmly adherent to the cervical fascia. Judd has described the operation, which was devised by C. H. Mayo, and has reported ten cases from the Mayo Clinic.[2] Cases have been reported by other surgeons in which the results of the operation, as far as the relief of symptoms is concerned, have not been entirely satisfactory. It may be noted, therefore, that an essential point in order to obtain a good result, is that the pouch should be drawn upwards as far as possible and fixed to the upper corner of the incision so that the opening points downwards. The opening into the pharynx is thus closed mechanically and food no longer tends to pass into the pouch instead of the œsophagus.

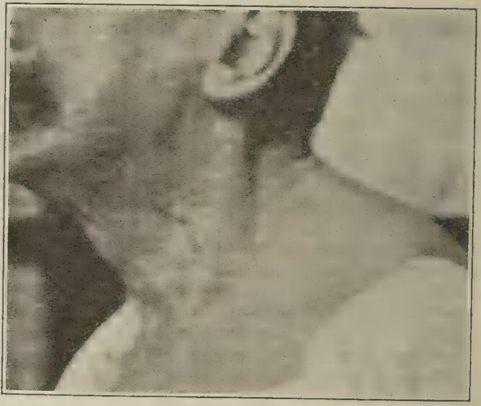
FIG. 2.



Appearance of pouch one week after first operation.

Some authorities have advocated the use of the œsophagoscope, both in the diagnosis and treatment of this condition. The use of this instrument appears to be unnecessary, and in dealing with a thin-walled sac, distended to a great size, by no means free from danger. The characteristic flask-shaped shadow, which the skiagram shows, is sufficient to put the diagnosis beyond doubt, and there is no reason for embarrassing the anæsthetist and complicating the operation by passing the œsophagoscope or a bougie into the sac. At operation the pouch may appear to originate at the junction of the pharynx and œsophagus. It has been shown by Killian[3] that actually it originates from the pharynx and passes between the oblique and horizontal portions of the inferior constrictor. His original paper on the subject contains a beautiful anatomical illustration which shows this very clearly and is reproduced in Sir StClair Thomson's well-known text-book.

FIG. 3.



Present condition of patient's neck. Wound completely healed.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

COMBINED SECTIONS OF MEDICINE AND SURGERY.

A meeting of these two sections was held on Nov. 27th. At the afternoon session Dr. Robert Hutchison, President of the Section of Medicine, took the chair, and Prof. P. Bull, of Christiania, read a paper on the

Surgical Treatment of Pulmonary Tuberculosis.

He referred in appreciative terms to this historic centre of medical science, and warned those of his audience who had heard him speak on the same subject at the Glasgow meeting of the British Medical Association that he had nothing new to tell them. He passed over all historical details and referred only briefly to treatment by artificial pneumothorax, devoting almost the whole of his lecture to the thoracoplastic operations. With regard to the indications for these operations, he insisted that, before they were attempted, an effort should have been made to induce a pneumothorax. If such an induction were successful, it were better to continue treatment by artificial pneumothorax than to adopt the more radical procedure. Generally speaking, the indications for artificial pneumothorax and thoracoplasty were the same, and it was most essential that the state of the healthier lung should justify the hope that the disease in it would remain latent. Should this lung show signs of progressive or extensive disease, no attempt at thoracoplasty should be made; to do so would merely be to bring the operation into bad repute. He had, however, been amazed to find how common cases of unilateral pulmonary tuberculosis were. In the selection of cases, with special reference to the state of the healthier lung, he had found the X rays of great value, and they had been the means of rejecting cases which, on the strength merely of a clinical examination, would have been considered suitable for a thoracoplasty. Among the many indications for this treatment were recurrent hæmoptyses, and he referred to a case in which these had occurred for 17 years, and had been permanently arrested by a thoracoplasty. He did not consider laryngeal tuberculosis or unilateral renal tuberculosis as a contra-indication, and one of his successful cases of thoracoplasty had had one kidney removed on account of tuberculosis, and the patient had since been able to work as a chauffeur without signs of recurrence of the disease. The general health of the patient must be comparatively good, a much debilitated patient being unlikely to stand the shock of the operation. Before this was undertaken, the patient should be under observation for some time in a sanatorium for two reasons: (1) to note whether the disease in the healthier lung was progressive or stationary, and (2) to ascertain if recovery might not be achieved by ordinary sanatorium treatment. In his discussion of the selection of cases for this treatment, Prof. Bull touched on the necessity for coöperation between the physician and the surgeon, and he referred to the harmonious manner in which he and his Norwegian colleague, Dr. Holmboe, of Mesnalien Sanatorium, had pooled their knowledge for the good of the patient. He added that the surgeon might be better qualified than the physician to lay down contra-indications in a given case.

Technique of the Operation.

Prof. Bull expressed his satisfaction with Sauerbruch's incision and stressed the importance of making the operation as radical as possible. The first rib must be included among those resected, the first to the tenth or eleventh ribs being included, an average of 130 cm. of ribs being resected. His minimum length of resected ribs in one case was 90 cm. and his maximum 180 cm. Altogether he had taken 125 yards of ribs from his 92 patients. The most difficult part of the operation was in connexion with the apex of the lung, and in order to ensure its adequate collapse, he performed apicolysis in every case, detaching the apex of the lung from the neighbouring structures, and maintaining its collapse by a fat graft taken from the abdominal wall. Half the right breast might also be used as an apical "stopping." With regard to the comparative merits of the one- and the two-stage operation, he had come to the conclusion that the latter was to be preferred, and whereas he had had a mortality of 30 per cent. among his one-stage operation cases, the operation mortality was only 4·5 per cent. for his two-stage operation cases. As for the anæsthetic, he had largely used local anæsthesia in his earlier cases, but had gradually been converted to the general anæsthetic. He had found it necessary to give morphine and omnopon after the operation and to keep a nurse in constant attendance on the patient for some time, one of her duties being to encourage the patient to expectorate freely. The dyspnœa from which some patients suffered after the operation would seem to be due, at any rate partly, to mediastinal flutter.

Results, Immediate and Late.

Prof. Bull said he had found that the disappearance of tubercle bacilli from the sputum before the patient's discharge after the operation was of great prognostic significance, and in as many as 47 of his cases there were no tubercle bacilli in the sputum on discharge. In 27 cases this important negative evidence of recovery had existed for one to nine years after the operation. He demonstrated a patient on whom he had performed thoracoplasty, as well as numerous illustrations, the chief lesson of which was that an amazingly free range of movement of the arm on the operated side was retained. The spine showed slight scoliosis, and in female patients the breast on the operated side pointed somewhat outwards. But these changes were trivial, and a casual glance at the front view of the patients would hardly give a clue to their having undergone this most radical operation. Prof. Bull was in favour of careful after-treatment in a sanatorium for three to six months and only gradual resumption of work. He was not in favour of such strenuous sport as ski-ing, but some of his patients had indulged not only in this sport, but in cycling and bathing. Prof. Bull amused his audience with an account of a patient who had lived at the expense of the community while he was ill and who, when he found himself restored to health by a thoracoplasty, felt aggrieved because it had robbed him of his claim on the community for sustenance. Several of the patients had been confined after the operation, undergoing labour and passing through the puerperium without complications. Of the 92 patients operated on, 46 were men and 46 were women. There were 33 deaths, nine of which were directly due to the operation. The cause of death in five of these cases was obscure, but it was probably due to flooding of the body with toxins from the compressed lung. In one case of obscure death, hæmorrhages into the stomach and small intestines were found post mortem. Some of the deaths were probably due to mediastinal flutter. In as many as 23 of the 33 deaths the cause was tuberculosis. Of the 59 survivors, 35 were rid of their symptoms, while 15 still suffered from tuberculosis. There were also nine patients about whom no definite results could yet be claimed. Altogether it might be stated that 47 of the 92 patients benefited by the operation, and it was noteworthy that the results were considerably better in the left-sided than in the right-sided cases. There were 56 of the former and 36 of the latter, and while there were only two operation deaths among the left-sided cases, there were as many as seven operation deaths among the right-sided cases. Prof. Bull also discussed the work of other Norwegian surgeons in this field, noting that 12 had performed a total of 135 thoracoplasties, among which there were 15 operation fatalities—i.e., a mortality-rate of 11·1 per cent. In conclusion, he insisted that the most important factor in the prognosis was the behaviour of the healthier lung after the operation, and that, as in the case of operations for cancer of the rectum, the operator must expect a certain number of relapses many years after the operation. But whereas in cancer of the rectum early diagnosis was essential if the ultimate results were to be good, in pulmonary tuberculosis the ultimate prognosis depended largely on a discriminating choice of patients for thoracoplasty.

Discussion.

Dr. **Clive Riviere** observed that the surgeon-physician was still an unknown entity in this country, and that when the surgeon coöperated with the physician, the latter should have the last word in the choice of cases suitable for thoracoplasty. He pleaded for careful observation of the patient in a sanatorium before embarking on this radical operation, which was an irrevocable step, whereas an artificial pneumothorax could be discontinued if it proved to be unsatisfactory. As for the choice of patients for lung collapse treatment, the ideal was to watch a case carefully from the beginning of the disease, but in his experience what usually happened was that, when first seen, the patient was already in a stage that was simply crying out for collapse treatment. He had found that, while interstitial pulmonary tuberculosis was almost invariably bilateral, parenchymatous pulmonary tuberculosis was not infrequently unilateral, and these were the cases suitable for lung collapse, provided the disease already showed a tendency to run a fibrotic, chronic course. He knew of no certain method by which the presence of pleural adhesions could be detected other than that of exploratory puncture, and he had been struck by the frequency with which comparative freedom from adhesions existed even in advanced cases. He had found it seldom necessary to cauterise adhesions in order to promote collapse of a lung, but he was greatly impressed by the value of phrenicotomy in certain cases. This operation had been performed in a case under his care, and the division of the phrenic nerve on the affected side had added appreciably to the limitation of the range of movement of the diseased lung. He had found that the condition of the heart in candidates for collapse treatment was often disquieting and that a state of general debility was a contra-indication; the patient must have a certain reserve of vitality if he was to emerge from the ordeal successfully. It was also essential that after-treatment should be prolonged.

Mr. H. **Morriston Davies** also spoke in favour of phrenicotomy which he had found beneficial not only in conjunction with an artificial pneumothorax but also by itself. He had known it to afford marked relief of persistent vomiting, and in conjunction with an artificial pneumothorax it was particularly valuable when the base of the lung remained adherent to the diaphragm. Turning to thoracoplasty, he noted that, in maintaining collapse of the apex of a lung, a live fat graft was superior to gas, and that paraffin and wax were liable to be extruded at a later date to the discomfiture of all concerned. In his last series of ten thoracoplasties he had had one operation fatality. He preferred the one-stage to the two-stage operation unless the patient was very weak, and he supplemented local with general anæsthesia, using only enough chloroform to keep the patient asleep. He used novocaine for local anæsthesia, and he had found that the injection of absolute alcohol into the nerves supplying the field of operation did much to relieve pain and prevent shock. With this system of poly-anæsthesia the patient suffered little, but it was advisable to supplement it for some time after the operation with omnopon which relieved the cough. He discussed the various methods by which band-like pleural adhesions could be divided, describing in some detail the operation with a tenotome under X ray guidance. The tenotome was used in such a way as to cut the adhesion with a sawing movement, and in one case he had found the adhesion to be so loosely slung between its two fixed points that its division was impracticable. He insisted on the resection of ribs in thoracoplasty being as radical as possible—the ribs from the first to the tenth inclusive being resected. He considered Sauerbruch's incision to be the best, and in children he recommended an axillary incision.

Resumed Discussion.

At the evening session, with Mr. **Cyril Nitch**, President of the Section of Surgery, in the chair, the discussion was resumed.

Dr. S. **Vere Pearson** expressed the opinion that in the choice of cases for thoracoplasty the indications ought to be weighed with even greater care than in the case of artificial pneumothorax. All the evidence for and against a thoracoplasty should be carefully weighed, and the decision should be finally come to only after such a comprehensive review and not on the strength of one or two signs. And in coming to a decision the physician should bear in mind the prognosis if no operation was attempted. The chances of an operation being successful might be poor, but was the outlook better or worse without an operation? He paid a sincere tribute to that great surgeon-physician, the late Prof. Saugman, and in his review of the various methods of dealing with pleural adhesions he argued that cauterisation under thoracoscopic control was a more scientific procedure than groping about with a tenotome under X ray control. He had explored the pleural cavity with a thoracoscope on nine occasions, and in two cases he had achieved considerable success in the cauterisation of adhesions according to the method of Jacobæus. He foresaw that this procedure, which he did not consider to be very technically difficult, would enjoy increasing popularity, and he discussed the methods most suitable for the prevention of surgical emphysema after puncture of the chest wall.

Mr. J. E. H. **Roberts** gave an account of a tour he had recently made of the Scandinavian countries, where he had found that the thoracoplastic operation most favoured was that in which extensive resection was practised, the ribs being resected not only to their angles, but as close to the transverse processes as possible. He emphasised the wisdom of judging the value of this operation by statistics embracing a large number of cases, and he insisted that a meticulous scrutiny of the state of the healthier lung might be carried too far, slight disease in this lung not being necessarily a contra-indication. In this connexion he had found standards vary in Scandinavia; Dr. Gravesen, of Denmark, took greater risks in this respect than did Dr. Key, of Sweden; while Prof. Bull, of Christiania, was still more exacting in the standard he set for the healthier lung. Personally, he was convinced that in some cases disease in the healthier lung might show improvement after a thoracoplasty on the opposite side. With regard to the anæsthetic used, he noted that the general tendency was to prefer general to local anæsthesia, and he had heard of several cases of serious novocaine poisoning in Sweden. Though the Scandinavian surgeons were, on the whole, practising the same technique, Prof. Bull was alone in his advocacy of apicolysis in association with thoracoplasty. Mr. Roberts insisted that after-treatment was quite as important as the operation itself.

Dr. L. S. T. **Burrell** deplored the fact that this country had been a laggard in the matter of lung collapse treatment, suggesting that a Mr. Carter was needed to dig and delve for talent in this field. He pointed out that phrenicotomy did not permanently paralyse the diaphragm, and he was not wholly in agreement with Dr. Pearson as to the simplicity of thoracoplasty and cauterisation and the frequency with which cases suitable for this treatment occurred. He stressed the fact that thoracoplasty was not a reversible procedure like an artificial pneumothorax, and he referred to numerous cases of artificial pneumothorax in which, on account of extension of the disease in the healthier lung, he had had to discontinue the injections of gas. When he had done so, the disease in the healthier lung had often become quiescent again. Such a retreat was impossible once a thoracoplasty had been performed.

Mr. Tudor Edwards described the technique of cauterisation of adhesions, and referred to observations on the blood pressure during local and general anæsthesia. He was in favour of the latter—i.e., gas and oxygen. Among the ten cases in which he had performed thoracoplasty there had been one death—on the third day after the operation. Whether it was due to embolism or heart failure he could not say.

Mr. C. F. Cuthbert described a pilgrimage he had recently made to Vejlefjord Sanatorium in Denmark and, though speaking as a surgeon, he emphasised the importance of the part played by the radiologist in the selection of suitable cases for thoracoplasty.

Summing up the salient features of the debate, Mr. Nitch commented on the unanimity with which the speakers had insisted that, before a thoracoplasty was attempted, treatment by artificial pneumothorax should have been given a fair trial. Another matter in which opinions seemed to be unanimous was that of the extent of a thoracoplasty; if it was to be undertaken it must be as radical as possible. The first rib must be resected as well as the second to the tenth or eleventh, and resection must be performed as close to the spine as possible.

Reply.

Prof. Bull, replying, traced the evolution of Norwegian medical science in relation to the outer world during the last century and a half. For about a century Norway had largely sought inspiration from England in this field, but during the past 50 years Norway had turned to Germany for much of her medical science. He suggested that the present movement in Norway towards a closer scientific union with England was not in the nature of rushing to the aid of the victors, but a natural reversion to an old and well-tried love, and he hoped that British scientists visiting him in Christiania would find their reception as cordial as his had been in London on the present occasion.

SECTION OF PATHOLOGY.

A meeting of this section was held on Nov. 20th, Prof. J. C. G. Ledingham, F.R.S., the President, being in the chair.

Evolution and Disease.

Dr. Francis Nopcsa read a paper on what he has termed "arrostic" changes in evolution (ἀρρωστία =sickliness). According to the author's definition, arrostic changes were such that when they occurred in an individual they must be considered as symptoms of some chronic or acute disease, but when they affected a phylum they did not seem to be harmful. Speaking broadly, the arrostic change in a phylum might be termed its chronic disease. The first case of "arrosty" quoted was the gigantic growth of some dinosaurs—e.g., the diplodocus. In these animals gigantic growth was associated with enormous development of the hypophyseal fossa and persistence of cartilaginous epiphyses of the limb bones, although the vertebræ were well ossified and showed dense structure. The author considered that these evolutionary changes were comparable to those which occurred in infantile gigantism in man. In this disease it was especially the closing of the epiphyses of the limb bones which was retarded while the hypophysis cerebri was greatly enlarged. An enlargement of the hypophysis was also seen in some fossil reptiles (dinocephalia). Here it was associated, not with gigantism and persistence of the cartilaginous epiphyses of the limb bones, but with tremendous thickening of the skull bones. Those covering the brain-case attained a thickness of more than six inches and their surface was very rough, showing that the thickening was due to periosteal changes. In both dinosaurs and dinocephalians the enlargement of the hypophysis cerebri was accompanied by a change of food which was clearly indicated by the form of the teeth. Since a change of the food of an animal might quite well affect its supply of vitamins, and since the vitamin supply would almost certainly affect the function of the ductless glands, it was possible that in both cases the change in the vitamin supply was the cause of their differing osteological changes.

The second arrostic change concerned changes observable in lung-breathing vertebrates not yet fully adapted to life in water. In those groups of reptiles which were ancestral to ichthyosaurians, plesiosaurians, and mosasaurians, and in the ancestors of whales there occurred a decided osteosclerosis and a remarkable periosteal thickening of the ribs. This vanished when the descendants of these groups became fully adapted to marine life. In the latter stage all these animals had huge well-developed lungs enclosed in a pleural cavity, and capable of very strong dilatation, and frequently also there existed retia mirabilia near the ribs and vertebræ. Considering that among other factors repeated stoppages of the air-supply could affect the bone marrow to such an extent that giant cells got into the blood, and considering further that many other factors could produce hyperplasia of the marrow followed by aplasia (e.g., benzol injections) the author felt induced to compare the osteosclerosis and pachyostosis of incompletely adapted marine vertebrates to those bone changes that accompanied leukæmia, a disease which was produced by hyperplasia and subsequent aplasia of the bone marrow. In contrast to human pathology, where leukæmia invariably led to death, the similar process in non-adapted marine vertebrates apparently healed in the history of their phylum. The healing might be due to the function of the large lungs in providing the necessary supply of air and the function of the retia mirabilia in preventing a hyperæmia of the marrow. In the well-adapted marine air-breathing vertebrates it was found that the ribs, instead of being thickened and osteosclerotic, were of normal thickness and of a highly spongy nature. The structure of the limb bones was also spongy, but there was no medullary cavity. These differences suggested that the periostitic thickening found in the ancestors of these groups disappeared, and that the bone marrow redeveloped in their descendants. Instead of redeveloping, however, in the medullary cavity (which in the meantime had been filled with bone), the marrow seemed to have developed equally in all those bone lacunæ which had persisted during the osteosclerotic phase.

Dr. Nopcsa pointed out that sea-cows were the only animals which seemed to form an exception to these conclusions. These animals were highly adapted to marine life, had well-developed organs for swimming, large lungs, and strongly developed retia mirabilia, but they had retained the pachyostosis and osteosclerosis. In some genera, as in the Polar rhyntina, the ribs showed an extraordinary thickening, and in other genera of this group this malformation extended even to the skull bones. An explanation of this exception could be found in their diet, for alone of all the marine air-breathing vertebrates the sea-cows feed on algæ. All algæ, and especially the circumpolar brown algæ, contained a high percentage of iodine. Experiments on dogs had shown that the amount of iodine in the thyroid gland increased if the animal was fed on an exclusively vegetable diet. In cases of athyroidism, thyroid extract, apart from its other activities, accelerated the formation of bony tissues. It was possible, therefore, that the peculiar diet of the sea-cows might well have an effect on the thyroid organ and might explain the persistence of the osteosclerosis. The author considered that besides the gigantism of dinosaurs and the osteosclerosis of the primitive air-breathing aquatic vertebrates, it was probable that the formation of horns and antlers would come under the heading of "arrostic changes," but in this connexion further study was required, although many characters could be discerned which associated these structures with pathological neoplasms. Some of these have been indicated in Dr. Nopcsa's book, "Die Familien der Reptilien" (Berlin, 1923).

Dr. **Oliver Heath** read a paper on the

Meaning of Fever.

His thesis was based on three main contentions—namely, (1) that the exciting cause of fever is the using up of antibody by the bacteria; (2) that the purpose of the change, indicated by the systemic symptoms of malaise and anorexia, as also of the specific immunity response, is directed towards the economy of the body energy, and (3) (the most important) that the purpose of the rise of temperature is to accelerate the production of antibody, either normal or specific as the case may be.

Taking typhoid as an example, Dr. Heath conducted experiments upon himself, by submitting himself to injections of known and carefully calculated doses of typhoid vaccine. The results of such experiments enabled him to draw certain conclusions, which he grouped under two separate headings: (1) the cause of a fever, and (2) the purpose of a fever. In his opinion, the direct cause of a fever, in a normal subject, was the using up of antibody, while bacteria played a secondary rôle. The mere presence of bacteria in the body—e.g., in a boil—did not necessarily cause fever, it was not until the bacteria came into contact with the blood fluids circulating through the lesion, or with the blood-stream, that fever occurred. It was known to laboratory workers that if, say, staphylococci were mixed with normal serum, or typhoid bacilli with a typhoid immune serum, the bacteria would absorb or render inert the antibody previously present in the serum. That effect could also be shown in vivo, for an experiment upon himself showed that the subcutaneous injection of 2000 mills. caused fever lasting 20 hours, with a hundred-fold decrease of bactericidal power in the blood. We have next, he said, to expand this idea to cover a fever such as that of the first week of typhoid before the appearance of specific immunity. Further experiments showed that a series of vaccine doses increasing daily from 50 to 600 mills. caused an intermittent fever slowly rising to the seventh day. On the fifth and sixth days fever was continuous, and the bactericidal power, twice tested, showed a decrease. This, he believed, represented the conditions in the first week of typhoid with a continued supernormal temperature and a continued subnormal bactericidal titre. The fever reaction was therefore a manifestation of reparative activity on the part of the blood tissue, damaged by depletion of antibody.

Accepting the depletion of antibody as the cause of fever, a problem arose in connexion with the immune subject: how did fever continue after the immunity had been raised considerably above normal? Experiment showed that where ten doses of vaccine were given, a definite level of immunity was established, which remained the same for two months, but was falling at six months, so that the old normal level was replaced by what might be called the new "immune normal," and this, barring disturbances, remained stationary for some time. Fever occurred only after doses, and with it there was a dip in the antibody content of the blood. Therefore some depression in the blood titre below this new "normal" was an essential factor in the causation of fever. In applying these observations to a case of typhoid fever, one could picture on one side the patient's reactive forces working to establish this new "immune normal," and on the other side the bacilli using up antibody at a rate which prevented its attainment. Just such a position of balances was very strongly suggested by the evidence of titre demonstrable during the fastigial period of typhoid, and records covering the defervescence very commonly showed results affording support to this view. If this view were accepted, it was reasonable to suppose that the cause of fever in the fastigium was still the using up of antibody.

Dr. Heath said that a consideration of the purpose of fever resolved itself into a study of the several events of the reaction, which he dealt with in some detail. Briefly summarised, the purpose of fever is to repair the damage caused to the blood equilibrium by depletion of antibody. This damage excited reactive impulses which (1) controlled local inflammation and rate of absorption; (2) inhibited normal activities and freed energy for defence; (3) in place of the normal defence process of local inflammation and a functioning body, this reactive impulse started two (abnormal) defence processes, which formed fresh antibody, and at the same time raised the temperature to accelerate its formation. Lastly, where specific immunity was exhibited, this enabled the patient to use his energy in greater comfort and in more economical fashion. If this thesis were accepted, the following practical conclusions should be drawn. (1) Vaccine during the fastigium of typhoid would only hinder the patient, while (2) vaccine during the first week of a mild typhoid would probably increase the immunity response; (3) the exhibition of antipyretic drugs should be put under the head of malpraxis; (4) the severity of the systemic symptoms of malaise and anorexia increased with the approach of the blood titre to zero, indicating rest of the whole body and abstinence from food; and finally, (5) it was possible, on clinical grounds alone, by observing the systemic symptoms, to form an approximate estimation of the state of the patient's immunity.

Papers were also read by Dr. E. E. **Atkin** on Cultural Characteristics of the Different Types of Meningococci, and by Dr. J. A. **Arkwright** on the Characteristics of Certain Cultures Sensitive to Bacteriophage.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

THE NERVOUS CHILD.

A MEETING of this Society was held in the rooms of the Medical Society of London on Nov. 29th under the presidency of Mr. R. C. **Elmslie**, F.R.C.S.

Dr. H. **Crichton Miller**, in introducing a discussion on the subject of the nervous child from the psychological standpoint, said those who were dealing with education in any shape must never let go of the fundamental conception that they were supervising a child who began life as an extra-social animal, and who had a long, tedious, and difficult pilgrimage from the outskirts of society in his efforts to reach its centre; and in that pilgrimage the child was called upon to make numerous new adjustments. In doing this he often fell behind or was lost. Our social life had become so complex and artificial that it was difficult to remember the complete simplicity of primitive life or to realise the actual fundamentals in the development of childhood and adolescence. Much of school life was also artificial and complex; whether it was necessarily so he would not stay to argue. Those concerned with the child had to watch it in its various phases, see how to get the most for it, and judge whether it was falling back. Many children entered the world "problem-children" from the very beginning, and no sort of educational environment would ensure a smooth pathway for them; they were mal-equipped for life's struggle. This was such a wide subject that he passed on to consider the case of the child with the normal equipment, who, given a fair environment and a decent chance, would develop into a psychologically and physically mature adult. Medical men in his own specialty were continually encountering nervous wrecks in adult life, whose wreckage could be traced back to a time in their development when they began to go off the lines. It was necessary to face the hideous fact that the teacher and the school would be beaten every time by the parent and the home; the former had not the last word, they could only do their best, and leave the rest. The child came to school with some of his development already achieved, but sometimes this was very little. At 7 or 8 years some of the shackles of the maternal magnetism ought to have been cast off and the child should be commencing to move with some independence, ready to get away from the fulsome admiration and protection of its mother. But some were far from doing so at that age, and that might be urged as a reason for not sending children to a boarding school so young. If the maternal protection were cut off too young a breakdown of some sort was to be expected; he showed he was unable to be independent of many different morbid reactions. A boy entering a public school at the age of 13 or 14 would be expected to have some independence, some aspiration after growth and development, and a readiness to take the consequences of his own actions. But, again and again, that was not so, the emotional development had been retarded. Inquiry showed, very often, that the father, instead of being a source of inspiration, had been a source of terror, and that the mother held on tenaciously to her emotional domination of the child. If at 14 a boy was still "mother's darling," it was useless to expect from him anything like a normal reaction to his social environment. This latter was largely a question of feelings of inferiority and of superiority. Children were naturally anxious to obtain a status in the eyes of their associates. Some tried to do it by "showing off," some by "bossing" and by violence, some by getting ill, some by becoming criminals. In many neuroses of children the dynamic motive was to acquire status in their social group, the school, and the root of this motive was a keen sense of inferiority, due to the fact that the world into which he had been projected was, largely, an adult world. The child who made good adjustments accepted this inferiority and succeeded. Those who did not sought to compensate by seeking a superiority by morbid means. The conflict between the attempt to assume superiority and the consciousness of inferiority produced the "nervous temperament."

With regard to the basis of sex, there was no question that the sexual life of the child was of enormous importance. He referred to four aspects of it. The first was enuresis nocturna, which he regarded as one of the most interesting symptoms in the whole of medicine. He would not encourage the use of electrical methods nor the passage of sounds, but the physical element depended on certain endocrine dysquilibria, probably associated with the pituitary and the thyroid. Many cases were cured by thyroid treatment alone. A second factor of great importance was auto-suggestion. The child who did this tended to be terrified at the prospect of a repetition, and this fear sufficed to perpetuate the act. A third factor was hetero-suggestion, the preparations at night with the waterproof sheeting and the other ritual connected with it. These children brought with them the symbolism of the cradle; they were victims of mother-traction. Scolding convinced the child that he was in the midst of a social scheme for which he had no use and which was unjust to him, and he therefore almost invariably turned to acts of revenge. With regard to masturbation, it was most important to keep the emotional atmosphere away from the whole subject. The solemn and sacred attitude of headmasters, chaplains, and others towards these delinquents was quite wrong, and it was very seldom their methods did good. The habit must be checked, but great harm was done to the child's character. It must also be remembered that every boy and girl passed through a phase of potential homo-sexuality; and when active homo-sexuality was found in a school child it merely meant that a smouldering fire had been fanned into a flame. He did not say schools should continue to be exposed to such. The adult pervert in this respect was quite a different proposition. Boys and girls so afflicted should be treated with a certain openness and generosity, less with the emotional lever, and more with that of psychology and biology.

Dr. H. C. CAMERON dealt with the subject from the physical side. The physical symptoms which commonly accompanied nervous exhaustion, he said, were most strikingly noted in the muscular system; there was a marked amyotonia of all the skeletal muscles, as shown in the lax, stooping stance. (He illustrated it by lantern slides.) It was especially manifested in the antigravity muscles. Standing with feet well apart, the child so balanced itself that as little muscular effort was expended as possible. This caused definite lordosis, and the abdomen was unduly prominent, with a compensatory curve in the cervical region. The chest became narrow, and the ribs descended steeply. The skeletal muscles also showed a loss of vasomotor tone, and flushing and paling were readily produced. The child's appearance evoked parental alarm, yet commonly there was no true anæmia present; it was rather a fault of blood distribution. Syncopal attacks, faintness or sickness in train or bus, palpitation, and a poor exercise tolerance were common complaints in these children. Functional murmurs and cardiac irregularities led to the fear of valvular disease, and he believed this to be the origin of the "effort syndrome" of Lewis. This type of child also had postural albuminuria. He did not regard the lordosis as the primary cause of the renal congestion producing the albuminuria, but thought both were due to failure of vasomotor tone. When this faulty posture had been maintained for long there might be detected increasing evidence of enteroptosis. Attacks of abdominal pain might synchronise with the times of emotional excitement, so that appendicitis might be suspected. These children also often showed a very irregular temperature curve; excitement raised the skin temperature perhaps a couple of degrees, and when the child was cold and exhausted it was subnormal. Probably this was due to variations in the circulation through the surface and deep areas of the body. These "nervy" subjects were also very prone to catch cold, as their vasomotor defences against chill were but ill developed. A very inclusive array of terms were applicable to these children. They were said to be timid, lacking in self-confidence, dreamy, inattentive, unmethodical, unduly sensitive, tearful, sleepless, suffered from night-terrors, refused food, had incontinence of urine, masturbated, had headache, habit spasm, and cyclical vomiting.

With regard to the treatment of the underlying exhaustion, it was very important to extirpate any source of chronic infection as a preliminary. On many cases chronic infection of the tonsils was acting deleteriously. The teeth also should receive careful attention. Often the child's condition was best attacked by carefully devised gymnastic exercises, drill, dancing, and massage. The exercises and the drill should be carried out in a warm room, the children being practically naked. This also had a good effect on the mind; on the soldier his drill conduced to mental smartness and celerity. Massage had great immediate effects on muscle tone and development. There was also need for systematic rest, especially of the antigravity muscles; the prone position, resting on the elbows, was probably best. Some form of skin stimulation seemed desirable. He favoured a hot bath, followed by short immersion in a cold bath, then a return for a short time to the hot bath, the aim being to get the stimulant effect without any considerable abstraction of heat. The final act should be vigorous rubbing with a rough towel. In many of these children a want of tolerance of fat could be detected. Attempts to feed them up by generous servings of milk, cream, and cod-liver oil often resulted only in vomiting or the passage of fatty stools. But the need and tolerance for sugar was high. Care should be taken not to dilate on the child's defects in his presence, as he was morbidly sensitive to all such influences. It was possible that the primary cause of the condition in these children was a deficiency of adrenal secretion. But he could not record with certainty any success from organotherapy.

Discussion.

The PRESIDENT referred to the difficulty of producing an alert posture in children of the type under discussion. A physiologist recently told him that the area presiding over postural tonus was in some of the basal nuclei of the brain. His own view was that this postural tonus was not, in human beings, a natural thing, as one would expect it to be if the basal ganglia were the seat. He believed children learned posture with great difficulty, and this would place the centre in the higher cortex of the brain.

Dr. C. E. **Shelly** (Haileybury) agreed that these children were largely the product of the neglect and discouragement of the child by the father and the over-fastidious endearment of the mother. He also thought the nutritional environment of the child, especially in the matter of white instead of wholemeal bread and pappy foods generally was an important factor in causing the condition. Fortunately, in some schools, there was a reversion to the old stone-milled flour ; 800 boys at Horsham were now given it.

Dr. E. H. T. **Nash** (school medical officer, Heston and Isleworth) referred to the difficulty in dealing with enuresis in school life, which was made more so by the absurd punishments sometimes inflicted, such as compelling the boy to carry his soiled clothes through the school and hang them up to dry. Another difficult type to deal with was that of the child who always had cold hands and feet, and he asked as to the ultimate history of these cases. Another type was the child with phobias ; treatment of these he had found very satisfactory. These children, especially if the victims of mother-traction, were liable to become pests to themselves and to everybody about them, and every care should be taken to avoid speaking about their ailments in their presence.

Dr. L. **Fairfield** (Public Health Department, L.C.C.) spoke of the type of child in regard to whom it was wrong and cruel to compel indulgence in gymnastics, as it needed mental gymnastics before attacking the clinical side. In the amyotonia subject it was the inferiority complex which was the dominant factor, and such a child was in great need of mental sustenance for getting rid of the inferiority idea. The jealousy complex should also be kept in mind, for it was often found to be a very definite factor.

Dr. L. R. **Lempriere** (Haileybury) said that in 2400 boys in his school he had seen 154 cases of the kind under discussion. When asked whether the nervous boy was fit for public-school life, his reply was that it was the best place for him, just as, in many cases, the home was the worst. Only two of the 154 could not stay at school ; they had very acute homesickness. His statistics did not show that this type of child was on the increase ; 68 of the 154 cases turned out to be good athletes. In school life the imitative faculty was important. He did not "fuss" these boys, and he found that physical training was of great value, but he insisted on their resting two days per week. For enuresis belladonna was the only drug he had found to be effective.

The openers briefly replied, Dr. **Miller** expressing his strong objection to the giving of belladonna, which was not only a poison, but a demoralising one.

Dr. **Lempriere** was elected the new President of the Society.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

A meeting was held at the rooms of the Medical Society of London on Nov. 22nd, Lieut.-Colonel E. **Goodall**, the President, occupying the chair.

The **President** referred to the sense of loss which the Association had sustained in the death of Dr. W. Ford Robertson.

The Psycho-Neurological Clinic at Utrecht.

Prof. D. C. **Winckler** gave an address, supported by a series of slides, on Psychiatrical and Neurological Teaching at the Dutch Universities, especially at the University of Utrecht. He said the organisation of the study of neurology and psychiatry at the Universities in Holland had been a very difficult matter. The Utrecht Society of Psychiatry was established in 1871, and it organised many petitions urging proper psychiatric instruction. In 1877 it succeeded in having an enactment passed which was entitled "A Law on Higher Education." At this time there were no recognised examinations in psychiatry, and medical men in asylums were recruited from among military medical men who had returned from the colonies. Donders strongly favoured the efficient teaching of psychiatry, and the lecturer's eyes were specially opened to the need by Dr. Leidesdorff, professor of psychiatry in Vienna. In this country it was the exception to have whole-time professors, but in Holland it was a stipulation that professors should not have private practice, a wise provision in some ways, but it did not ensure that the professor was necessarily the best man on the subject. In Holland, the paying patient constituted a great financial help to the teaching schemes. The 1877 law permitted the establishment of the Amsterdam Municipal University, the Faculty of Medicine of which operated in that city.

In 1885 Prof. Winckler was nominated a university lecturer on psychiatry and neurology, and money was set aside for research. The Society of Psychiatry held a number of discussions on the need for the teaching of neurology and psychiatry by one professor. The chief opposition to this idea came from practising specialists. He showed how intimate the two subjects were, and that to place the tuition in separate hands must result in overlapping. He contended that even a skilled neurologist was not necessarily a psychiatrist ; moreover, psychiatry based only on psychology had proved dangerous, as witness Weinroth's contention, in 1882, that "All alienation reposes on sin." In many asylums the clergyman was accepted as the leader, the physician being relegated to a secondary place. Later the Society took the ampler title of "The Society of Psychiatry and Neurology," and the two departments were successfully fused. At the Utrecht University students could not be trained as specialists before passing their final examination.

It was now possible, as a result of various controversies, to retain specialism within certain limits, but he was anxious as to the future. A project was successfully started for building a clinic of psychiatry and neurology in Utrecht, but as it was to cost £50,000 some hesitation was felt, and the authorities argued that the best place at which to teach psychiatry was the asylum. This, however, was opposed by the Society, and by the Faculty of Medicine at the University, chiefly on the ground that cases of the various transient psychoses, hysteria, neurasthenia, and hypochondria, &c., were seldom seen in asylums. Matters remained stationary from 1885 to 1891, but in 1892 everything seemed in readiness for commencing the new building. However, a small mistake on the part of the architect led to a controversy between the State and the municipality, and there was a further delay.

Dr. Winckler paid a tribute to the energy and perseverance of Dr. Weilbronner, which culminated in the establishment of a new clinic. He did not survive beyond 1914, his death being sudden ; and Dr. Winckler succeeded him, becoming director of the newly-built clinic of psychiatry and neurology. It had to fill a double rôle : to secure the best possible care to nervous patients, and give them the best chance of recovery ; secondly, to give teaching in psychiatry and neurology. Here all patients were nursed on the ground floor ; the scientific installations, laboratories for photography, Rontgen rays, &c., on the first floor, and the higher floors were used by house doctors, administrative staff, nurses, &c. The lecture-room was placed between the wards on the ground floor. He described the equipment and the plan of working by the aid of some excellent photographs. The dispensary was visited by 1200 new patients per annum ; and the lecture-room had accommodation for 145 students. In the library department a special feature was the scheme for filing ready for immediate use all the photographs, micro-photographs, skiagrams, &c., taken ; and for each subject there was a definite series of slides. He showed that there exists a happy spirit of coöperation with the justiciary as well as with the other departments of the University. The average residence in the clinic was three weeks, but some patients stayed there much longer.

The President expressed the Association's gratitude to Prof. Winckler for having come so far to show the high level on which psychiatry stood in Holland.

Sir Frederick Mott said it had been his privilege to see the fine institution which Prof. Winckler directs, and on his recommendation, other English alienists visited it, and came back with a fund of instruction. When William of Orange rode into Leiden, after the siege, he asked the burghers whether they would have a university or a remission of taxation, and they chose a university. Sir Frederick Mott wondered in how many English towns such a choice would be made. In conclusion, he referred to the many-portal system of entry to the medical profession in this country, and commented on the advantages of a single State examination.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A meeting of this Society was held in Sheffield on Nov. 16th. Prof. M. H. Phillips was in the chair.

Exhibition of Cases and Specimens.

Dr. J. Bride (Manchester) showed a tumour simulating complete ulcerated prolapsus uteri. He removed it from a 2-para, pregnant four months. It was situated in the interval between right labium majus and minus, and resembled an ulcerated complete prolapse. It had been noticed for 12 months and was steadily getting bigger and was removed without affecting the pregnancy. Microscopically it was a fibroma.

The President showed specimens of (1) adenomyoma of rudimentary uterine cornu; and (2) salpingo-cæcal fistula. The first specimen was removed from 7-para aged 44, who had had menstrual pain for the last seven years and recently pain not associated with menstruation. A swelling the size of a golf ball was attached to the left side of the supravaginal cervix, diagnosed as adenomyoma of Gaertner's duct. At operation it was found to be rudimentary, left cornu of uterus attached to supravaginal cervix, and also to pelvic wall. A section of the cornu showed spaces filled with dark blood, lined by columnar or cubical epithelium, embedded in "cytogenous mantle" similar to uterine endometrium. The second specimen was removed from 3-para aged 32 years. Last child was born three years ago, followed by severe abdominal pain for two weeks. Patient was admitted into hospital in November, 1922, suffering from subacute attack of bilateral salpingo-oöphoritis. Five weeks later she was seen with fixed tender swelling to the right of the uterus which was thought to contain pus. Four weeks afterwards swelling had disappeared and the patient felt much better. She was readmitted August, 1923, for dysmenorrhœa and backache. A retroverted adherent uterus and slight enlargement of the appendages were found. The right tube was firmly fixed to the cæcum, and the thickened area of the cæcum was removed with the tube. The end of the tube was found prolapsed into the cavity of the cæcum, the ostium being patent and well away from the opening of the vermiform appendix. The condition was thought to be the result of rupture of the peritubal pyocele into the cæcum.—Dr. Bride recalled a similar case in which an ectopic pregnancy had ruptured into the cæcum.—The President said that originally this case had been diagnosed as an ectopic cyst by the house surgeon.

Dr. Bride gave an account of two consecutive pregnancies with central placenta prævia and Cæsarean section. A 2-para, aged 34, was seen on Nov. 20th, 1922, three months pregnant, with history of Cæsarean section, by Dr. Fothergill, whom the speaker had assisted. The living child then delivered was still alive and healthy. On April 21st, 1923, the patient was admitted into hospital eight and a half months pregnant; she had severe bleeding with central placenta prævia. Dr. Bride decided to do Cæsarean section, delivered a living child, and at the same time sterilised the woman by removing portions of both Fallopian tubes. The child died of convulsions on the eleventh day. Nothing was found to account for the placenta prævia habit.—Dr. J. E. Stacey said that it was very rare to have recurring central placenta prævia.—Dr. W. W. King asked to what extent the cervix was dilated and criticised the second Cæsarean section, and also the sterilisation of the patient.—Dr. Fletcher Shaw said that one did not expect a Cæsarean scar to stand difficult deliveries in future pregnancies.—Dr. Bride said that the cervix was only slightly dilated; he did not consider possible rupture of the old scar. At operation the old scar could hardly be seen.

Dr. H. Clifford (Manchester) described a case of full-time ectopic gestation. Mrs. F. was admitted to hospital on Nov. 30th, 1922, with a history of amenorrhœa since February, 1922. Fœtal movements were active till two days before admission. The fœtus appeared to be full-term, fœtal limbs were rather prominent, the head high up and in R.O.P. position. No fœtal heart sounds were heard nor movement felt. The cervix was protruding from vagina; presenting part could not be definitely felt. Radiographs gave no assistance; the temperature was slightly raised; the cervix was cleansed and replaced and supported by a ring pessary. Labour did not come on and the patient was discharged at her own request on Jan. 5th, 1923. She was readmitted on the 26th when the fœtus was in the same position, and the temperature was slightly higher. Bougies were inserted into the cervix on two occasions, but could only be pushed 3½ inches. Temp. 102° F. and pulse 120. On Jan. 29th and Feb. 4th the patient had 4-minim doses of Dr. Jenkins's stock residual vaccine.[1] On Feb. 14th Dr. Clifford opened the abdomen and found a full-term macerated fœtus lying in a sac with placenta almost entirely attached to outer abdominal wall. This was stripped off without bleeding; the membranes were not removed and the cavity was drained and irrigated by Carrel Dakin's method for three weeks. The cavity rapidly became smaller, and six weeks after operation there was a sinus 1½ inches long. Inquiries afterwards revealed the fact that in March, 1922, the patient had severe abdominal pain with vomiting followed a little later by hæmorrhage lasting five days. Afterwards she had considerable abdominal pain, and in May consulted a surgeon who thought she had had appendicitis. Dr. Clifford considered that the condition was very difficult to diagnose.—Dr. Fletcher Shaw and Dr. D. Dougal agreed with him.—The President also agreed, but pointed out that a dead fœtus is not retained long in utero.—In reply, Dr. Clifford said that it was sometimes very difficult to diagnose fœtal death.

Dr. S. B. Herd (Liverpool) described two cases of encephalitis lethargica associated with pregnancy: (1) Primipara aged 24. No history of previous illness. Pregnancy normal up to thirty-sixth week. The patient then had headaches, albuminuria, and slight œdema of the ankles. She had treatment and showed signs of temporary improvement. A week later she had severe headaches and a fit. Admitted to hospital: Blood pressure, 130 mm. of Hg; albuminuria, 3 g. per litre. No uterine contractions. The patient had six fits in six hours following admission—apparently typical eclamptic fits. Next day a living child was delivered. Later in the day rhythmic clonic contractions of jaw muscles commenced. The temperature was slightly raised. The patient was restless and confused, and at the end of five days, as she was becoming worse, was transferred to another hospital, where she died on the twentieth day after delivery. She had nystagmus, ptosis of upper eyelid, and weakness of facial muscles. Post-mortem diagnosis of encephalitis lethargica was corroborated, and no evidence of toxæmia was found. The second case was that of a primipara aged 28. Healthy up to the thirty-fifth week of pregnancy. On admission the patient was restless and excited, and there were incoördinated clonic movements of head and limbs present during sleep. Reflexes normal. Albuminuria, 2 g. per litre. Chorea gravidarum was diagnosed and treated with parathyroid extract, calcium lactate, and sedatives. On fourth day after admission the patient was delivered of a still-born child. The temperature rose to between 100° to 102° F. Diplopia noticed on following day. Delusions, restlessness; became worse, and was transferred. Diagnosis of myoclonic lethargica encephalitis was made. The patient was slowly recovering—four months later—but complete recovery was not expected.

---

[1] Brit. Med. Jour., April 15th, 1922.

Dr. J. Chisholm recalled one case in a 2-para with marked clonic movements of abdominal walls with symptoms of internal obstruction. Cæsarean section was performed; no obstruction was found and movements continued afterwards. The patient was dull and apathetic, but recovered. The child also had lethargic encephalitis. Dr. Chisholm mentioned another case in a five and a half months' pregnancy diagnosed as pernicious vomiting at first. Though labour was induced, the patient died. She had nystagmus also.

Dr. Fletcher Shaw read a paper on the

Advantages and Disadvantages of Supravaginal Hysterectomy and Panhysterectomy.

He said that some gynæcologists believed panhysterectomy should be done whenever the uterus had to be removed, while others believed that supravaginal hysterectomy was the better operation for many cases, though they would probably always do panhysterectomy if the cervix was badly lacerated. In a period of 18 months he had had three patients in whom carcinoma of the cervix occurred after supravaginal hysterectomy, and his object in bringing the subject before the Society was to see if other gynæcologists had had any similar cases. Although these three cases were seen in a period of 18 months, they were the only ones he had ever had, and so far as he knew none of his colleagues at St. Mary's Hospital had had a single case, so that the occurrence after supravaginal hysterectomy was very rare and it was probably merely a coincidence that he should get these three in so short a period. If that proved to be the case he still thought there was a distinct use for supravaginal hysterectomy, as it was a much quicker operation and caused less shock to the patient and, moreover, did not entail the opening of the vagina, which, no matter how carefully cleaned, was potentially a septic passage. In a consecutive series of supravaginal hysterectomy and panhysterectomy he found the mortality higher after panhysterectomy, and in the investigation of the convalescence of a consecutive series of both types the patients after supravaginal hysterectomy had, on the whole, a smoother time than those in whom the complete operation had been done. He still thought supravaginal hysterectomy was useful in nulliparous women, but panhysterectomy should always be done where the cervix was badly lacerated or in any way diseased.

The President said that he did not remember seeing carcinoma of the cervix after subtotal hysterectomy, but he had removed cervices for discharge. He believed that panhysterectomy was the better operation in all cases.

Dr. W. W. King showed a specimen of carcinoma of the cervix which he had removed. The patient had subtotal hysterectomy in 1919 for fibroids. In 1923 she had bleeding for three months, and the cervix was found carcinomatous. He recalled another case in a nullipara who in 1911 had gonorrhœa. In 1918 the patient had a pelvic abscess drained; in 1920 had subtotal hysterectomy for bleeding, and six to eight months later had ineradicable carcinoma of the cervix. He believed in total hysterectomy in multiparæ, and subtotal in nulliparæ.—Dr. Bride said that in a case of a nullipara, he had done a panhysterectomy and found an early carcinoma of the cervix.—Dr. Chisholm mentioned a case who had had a subtotal hysterectomy 25 years ago and who had bleeding for two months, and was found to have ineradicable carcinoma. She had had one child and one miscarriage.—Dr. Clifford did not remember a case of carcinoma of the cervix occurring after subtotal hysterectomy in his practice. He said that it was so rare that it hardly affected the difference in the mortality rate between the operations of subtotal hysterectomy and panhysterectomy.

ULSTER MEDICAL SOCIETY.

A meeting of this Society was held on Nov. 22nd, Prof. W. St. C. Symmers, the President, being in the chair.

Mr. Andrew Fullerton read a paper entitled

Observations on Unilateral Diuresis.

He described a continuation of some observations on unilateral diuresis which he presented last year before the Congress of the American College of Surgeons, held at Boston. A small irritating calculus in the pelvis of the kidney, he said, may give rise to a unilateral diuresis so definite and striking as to confirm the most casual observer. The flow from the sound side may be correspondingly diminished, and the specimen so concentrated that a copious deposit of urates is rapidly precipitated. In tubercle of the kidney an exactly similar state of affairs is present in the early stages. A further example was furnished by unilateral pyelitis. In cases with little involvement of the parenchyma of the kidney the picture closely resembles that seen in stone in early tubercle. In stone and pyelitis a rapid return to the normal occurs when the cause has been removed. In calculus and in the early stages of tubercle the diuresis is what may be termed acute. When structural changes have occurred in the kidney the specific gravity is still diminished, but by degrees the flow of urine becomes less and less, until finally all the work falls on the sound kidney. The term chronic might be applied to the diuresis in these cases, but when the flow becomes diminished it is not strictly applicable. The specific gravity of the urine in the affected side was likely to be low in the following conditions: renal calculus, tuberculosis of the kidney, unilateral pyelitis, tumours of the kidney, congenital cystic kidney (when the process is more advanced on one side), hydatid cyst of the kidney, hydronephrosis, movable kidney, certain cases of renal pain, and in wounds of the kidney. Statistics were given of the results of examination in over 500 cases. Mr. Fullerton brought forward this subject to emphasise the value of a sign that might help in diagnosis when the surgeon was deprived of more accurate methods.

Dr. F. C. S. Bradbury demonstrated a method of

Estimating Urea in Urine,

based upon the principle that if a gas is liberated within an apparatus of constant volume, the resulting increase of pressure is proportional to the amount of gas liberated. In this method the ordinary hypobromite reaction is utilised to liberate nitrogen from a fixed volume of urine, and is carried out in the usual manner by placing the urine in a small test-tube within a bottle containing the reagent, so that by tilting the bottle the urine and reagent can be mixed at will. The bottle is provided with a perforated rubber stopper into which is pressed the stem of a manometer such as forms part of a sphygmomanometer outfit of the aneroid pattern. The air space within the apparatus has a complex value, being the capacity of the empty bottle minus the amounts of caustic soda, bromine, and urine added; minus the volume of the glass composing the bromine tube and the urine tube; minus the volume of air displaced by the stopper of the bottle; plus the air space inside the manometer; plus the potential air space in the reagent due to its power of dissolving nitrogen. It is thus not easy to standardise the apparatus so that it shall have a constant air space, but Dr. Bradbury finds that the air space is brought to a sufficiently constant value by adjusting the amount of caustic soda in accordance with the size of the bottle used. The reagent thus serves a double purpose—to liberate nitrogen from the urine, and to bring the air space within different pieces of apparatus to the same amount. To facilitate the use of the apparatus the urine tube is marked at a level corresponding to 5·0 c.cm., and the bottle is marked at a level corresponding to 177 c.cm. less than its total capacity. By choosing this particular value for the amount of caustic soda (in conjunction with a 2 c.cm. tube of bromine), and using 5 c.cm. of urine, the reading of the manometer in decimetres expresses the percentage of urea in the urine, the reading being taken as soon as the reaction is complete, without waiting for the apparatus to cool. A series of 73 estimations controlled by the urease method of urea determination showed the average error of the manometric method to be 3 per cent.

CORK UNIVERSITY SCIENTIFIC AND MEDICAL SOCIETY.

MEDICAL SECTION.

Exhibition of Cases and Specimens.

THE opening meeting of the session was held on Nov. 6th, with Prof. C. YELVERTON PEARSON in the chair.

Dr. M. CAGNEY showed a case of mitral stenosis with aortic incompetence and pericardial adhesions, which was remarkable for the almost negligible rheumatic history in comparison with the extensive cardiac damage. Prof. D. T. BARRY demonstrated pulse records of this case, which showed a pulsus alternans which was not appreciable by palpation of the radial pulse.

Dr. J. B. HORGAN described, with specimen and X ray photographs, a case of

Right-sided Hypopharyngeal Diverticulum

in a male aged 32. There was a history of dysphagia lasting over two years, with regurgitation half an hour after food, and marked inanition. A slight swelling was present at the right side of the neck, and the œsophagoscope passed readily into the pouch, and it was only by employing a small tube and using pressure that the instrument could be passed beyond the pouch into the œsophagus, which was normal. The patient was fed liberally by a Hill's feeding-tube for two days before operation, which was performed under general anæsthesia administered by laryngeal intubation, the incision being made from the hyoid bone to the right sterno-clavicular articulation in front of the right sterno-mastoid. The base of the sac was clamped and the sac removed, its opening being closed by three layers of chromic gut suture, and the wound packed with gauze round a drainage-tube. Recovery was uneventful, swallowing being quite well performed when the Hill's tube was removed nine days after operation.

Prof. PEARSON presented a case of

Pyometra Due to a Suppurating Fibro-myoma.

The interesting point about the case was that manual removal of the placenta had been performed on the patient a year before after a difficult labour, and at that time the obstetrician had noticed no intra-uterine fibroid. When the patient came under Prof. Pearson's care there was great uterine enlargement, with pyrexia. A few days later some two pints of pus containing *Staphylococcus aureus* were spontaneously evacuated from the uterus, and on examination the tumour was felt blocking the internal os, where it acted as a ball valve. Pan-hysterectomy was performed after douching the vagina and packing the vagina and cervix with gauze. Recovery was uneventful, though previous to operation the patient's condition had been very bad.

Dr. P. KIELY demonstrated two cases of successful use of

Radio-therapy for Rodent Ulcer.

In one of these cases, a large rodent ulcer involving the bridge of the nose, inner canthus of left eye, and both lids of the right eye, considerable improvement had taken place. He emphasised the need for patience, as even in apparently hopeless cases involving deeper structures the X rays would bring about marked improvement. Photographs were shown of the patients before and during treatment.

Dr. R. C. CUMMINS demonstrated a case of

Amœbic Liver Abscess,

with partial right-sided pyo-pneumothorax. The patient had been on active service in India, Egypt, and Mesopotamia, and had suffered from malaria, but had never suffered from any intestinal symptoms except occasional slight diarrhœa. There was thus no dysenteric history. Amœbæ were found in the copious sputum, along with various catarrhal organisms. The condition was treated with emetine bismuth iodine, 1 gr. daily, for ten days, with weekly injections of a vaccine prepared from the sputum. After an intermission of a week a further course of emetine was given and symptoms cleared up completely. The case was interesting in view of the report of investigations by the Medical Research Council in 1917 in which, after examining the fæces of 3000 apparently normal individuals, it was found that 10 per cent. were infected with *Entamœba histolytica*, and this in persons who had never left Great Britain. The importance of this possibility in explaining otherwise unaccountable attacks of recurrent diarrhœa was urged.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the Committee 43 cases were considered and £499 15*s.* voted to 34 applicants. The following is a summary of some of the cases relieved :—

L.R.C.S.I., aged 65, who practised in London and through paralysis has been unable to work regularly. One daughter is out of employment, the second one is married, and the youngest has a post of 30*s.* a week and is unable to help her father to any great extent. The Fund gave an emergency grant of £3 and voted at this meeting £18 in 12 instalments.

Widow, aged 81, and daughter, aged 55, of L.R.C.S. Edin. who practised in Birmingham and died in 1918. Their only source of income is derived from selling eggs and from the mother's Old Age Pension. The daughter reckons to get about 15*s.* from the sale of eggs. The bungalow is their own and unfortunately was partly burnt. The estimated damage was £18 and they were uninsured. This case was voted £9 in six instalments (to the mother) and £10 towards the damages through the fire (to the daughter).

Widow, aged 26, of M.B. who practised in Wales and died suddenly in May of this year. Applicant was left penniless. Her baby was not born until July. She tried to sell the panel, but the Workmen's Medical Committee claimed to elect whom they chose to fill the vacancy. Friends helped with the funeral expenses. Applicant's late husband had only been in practice for one year and was unable to make any provision. Voted £20 in two instalments.

Widow, aged 69, of M.R.C.S. Eng. who practised in Nottinghamshire and died in 1915. Applicant lives with her daughter who, owing to bad trade, finds it most difficult to provide for herself and her mother as the applicant has no means of her own. Voted £18 in 12 instalments.

Widow, aged 62, of L.R.C.P.I. who practised in Lancashire and also acted as a ship's surgeon and died in 1902. Since the death of her husband she has maintained herself by acting as a companion and up to two years ago had a permanent appointment, but owing to her health breaking down she is now only able to take temporary employment or do needlework. During the last twelve months she has only received £10 from needlework and £20 as temporary companion. Her daughter and sister have given some assistance towards rent and food, but owing to their own slender means are unable to assist to any great extent. Applicant's rent is £26 per annum. Voted £18 in 12 instalments.

Widow, aged 46, of L.R.C.S. Edin. whose last appointment was in South Africa and where he died three weeks after landing. The War Emergency Fund helped considerably whilst the applicant's late husband was searching for an appointment and materially helped to get the South African post. Applicant is now destitute and only one daughter earning a small salary, as an actress. The applicant has been in hospital with heart trouble. Voted £5 and case to be reconsidered.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., at 11, Chandos-street, Cavendish-square, London, W.1.

Reviews and Notices of Books.

LEGAL MEDICINE AND TOXICOLOGY.

Second edition. Edited by **Frederick Peterson**, M.D., LL.D., **Walter S. Haines**, A.M., M.D., and **Ralph W. Webster**, M.D., Ph.D. London and Philadelphia: W. B. Saunders Company. 1923. Two volumes. With 334 illustrations. Pp. 2268. £5.

It is now many years since the first edition of this work appeared, and it is gratifying to see a new and thoroughly revised edition. As in the former edition, the sections have been written by a variety of authors, the whole work being supervised by two editors; but in this edition a third editor—namely, R. W. Webster—has been added. Vol. I. deals with forensic medicine, and the usual subjects included under this heading are in the main well discussed. The introduction of a chapter on the Bertillon System of Identification, profusely illustrated, is particularly interesting. The sections of this volume are written from the broadest medico-legal standpoint, with the result that at times those parts of medico-legal work in which medical men most frequently require help—namely, criminal jurisprudence—do not receive all the detailed attention which the subject justifies. This is the case, for example, in the chapter on abortion. The medico-legal importance of accidental injuries and insurance are so vast that the space allotted to them does not permit of thorough treatment, even when certain classes of injuries only are discussed. Nevertheless, the material is good, and the reader can always pass on from this book to special works dealing with these subjects. Readers are reminded that the authors are reciting American law, and that the English law, although the same in principle, may vary considerably in detail.

Vol. II. deals with toxicology, asphyxia, and the examination of blood, semen, and hairs. The analytical details for the various poisons are well described, and the methods given are practical and up to date. The tendency in some places is towards over-elaboration of detail in order to purify the poison isolated, which might result, in the case of small traces, in the failure to detect the substances in question owing to loss in the process of purification. A coloured plate of alkaloidal "changing colour" reactions is useless, as anyone who has practical experience of these tests knows, and should be omitted. It is rather unfortunate that the authors do not indicate, when alternative methods of analysis are given, which in their opinion is the most useful, and when a number of tests for a particular substance are given the reader would gladly learn which test or tests are to be regarded as specific to the substance in question. It is noted with satisfaction that in the majority of cases where a reagent is directed to be used the strength and the amount required for the test is stated, instead of vague statements such as "dissolve in soda," which so commonly occur in text-books.

The bibliography is excellent, and copious references both of cases and analytical records are given. Both volumes are well indexed, and Vol. II. has, in addition, a general index.

ANÆSTHESIA.

Handbook of Anæsthetics. Second edition. By **J. Stuart Ross**, M.B., Lecturer in Practical Anæsthetics, University of Edinburgh. Edinburgh: E. and S. Livingstone. 1923. Pp. 328 and illustrations. 8*s.*

This excellent little work has been enlarged and revised. Its character is unchanged and it still possesses the merit which originally distinguished it—viz., that it teaches the student sound general principles and their foundation rather than confusing him with a heterogeneous mass of clinical details and descriptions of apparatus. The chapter on asphyxia (anoxæmia) is particularly good, and the author has made capital use of the most recent work of Haldane and other physiologists. The general teaching is identical with that to be found in English text-books, and the traditional Scottish preference for chloroform has no attraction for Dr. Stuart Ross. In the chapter on choice of anæsthetics the advice is sound and logical, but we would like to have seen included the consideration of cases of advanced intestinal obstruction with regurgitation—a condition which, when present in very obese subjects, offers one of the most formidable problems that the anæsthetist is ever called to face. The author suggests that insulin might usefully be tried in the treatment of post-anæsthetic toxæmia. There are one or two unimportant misprints (p. 140, "there" for ether) and Trendelenburg's name is consistently misspelt. The book has no superior among those of its own size on the subject with which it deals.

Die Methoden der Lokalanästhesie in der Bauchchirurgie und ihre Erfolge. By Prof. Dr. **Hans Finsterer**, Primarius der chirurgischen Abteilung im Spitale der Barmherzigen Brüder zu Wien. Berlin and Vienna: Urban and Schwarzenberg. 1923. With 42 diagrams. Pp. 196.

Prof. Finsterer is a warm advocate of local anæsthesia for all big abdominal operations. Although sometimes he supplements local with a certain amount of general anæsthesia, he uses this technique almost exclusively in comparatively young subjects. The more extensive the operation required the more anxious is he to restrict anæsthetics entirely to those of local action. In order to get the necessary insensibility in such proceedings as resection of the stomach he has recourse to splanchnic injection, mere infiltration methods being insufficient to obviate pain and disturbance produced by interference with the mesentery. Splanchnic analgesia he carries out by the method advocated by Braun—viz., by injecting the solution into the splanchnic area from the front, after the abdomen has been opened. He prefers this to the posterior entry of Kappis and Nägeli, and is thoroughly opposed to the blind entrance through the anterior abdominal wall. The solution he employs is novocaine, usually in about ½ per cent. strength. Preliminary hypodermic injections of omnopon and of morphia and atropine are used. The chief reasons which the author gives for his strong preference for local anæsthetics for abdominal operations suggest that he has not been helped by the best forms of general anæsthesia, and also that the procedures are longer than those customary in Great Britain for identical conditions. It is the post-anæsthetic morbidity due to toxic effects of very long deep administrations and to consequent pulmonary and cardiac affections that Prof. Finsterer finds a bar to the employment of general anæsthetics. In fact, he maintains that the chief cause of mortality or of delayed recovery after serious abdominal operation is the general anæsthetic, when that is employed. Obviously, if this premise is correct, the conscientious surgeon has no alternative but to adopt local methods of anæsthesia in spite of their disadvantages, admitted by Prof. Finsterer, of requiring much more time and trouble from the operator. The author states that he has seen no instance of post-operative shock within 24 hours when he has employed local anæsthesia. Acute dilatation of the stomach, however, does occur as it does after narcosis. Psychic disturbances in the absence of general anæsthesia are entirely prevented, Prof. Finsterer states, by his two preliminary hypodermic injections. The author does not care for sacral analgesia because he regards the large amounts of solution required as providing a danger, nor is he a strong supporter of spinal injections, the effect of which does not last long enough for his purposes. His work is based on an experience of 2408 operations, of which 2186 were performed with the use of novocaine, and of these 1447 were done without any assistance from a general anæsthetic.

After general considerations of different forms of anæsthesia and their applicability to slight and to severe abdominal operations the latter part of the work is given up to detailed description of the use of local anæsthesia in various abdominal operations from small procedures for hernia to extensive resection of the stomach for malignant disease. The book is a valuable addition to the literature of abdominal surgery.

DISEASES OF THE MALE ORGANS OF GENERATION.

By KENNETH M. WALKER, F.R.C.S., M.A., M.B., B.C., Lecturer in Venereal Diseases, St. Bartholomew's Hospital; Surgeon in Charge of Genito-Urinary Department, Royal Northern Hospital and Miller Hospital. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 234. 12*s*. 6*d*.

THIS volume gives a good account of present-day knowledge of the diseases of the generative organs in man. It is not intended to be an exhaustive treatise to which the specialist may refer, but to form a guide to the practitioner. Diagnosis is fully considered and the grounds upon which prognosis should be based. Minor surgical measures are described in detail, whilst of major procedures, only the main facts are given. The author is most interesting when he writes on those subjects which he has particularly investigated, enlargement of the prostate and tuberculous infection of the urinary tract. Throughout the book there is a commendable absence of extreme views. Thus the operations of vesiculectomy and vesiculotomy are advised only when the patient's health is seriously affected by the disease, whilst the restricted possibilities of orchidopexy are stressed. We note that the author regards inversion of the sac in chronic hydrocele as an uncertain operation, and rightly so. More emphasis might have been given to this view, as also to the fact that injection of a hydrocele with irritants not only frequently fails to cure but also may give intolerable pain.

The practitioner who is guided by the recommendations in this book will not go far wrong.

STUDIES OF THE ATOM.

The A B C of Atoms. By BERTRAND RUSSELL, F.R.S. London: Kegan Paul, Trench, Trübner and Co., Ltd.; New York: E. P. Dutton and Co. 1923. Pp. 175. 4*s*. 6*d*.

The Structure of the Atom. By E. N. DA C. ANDRADE, D.Sc. Lond., Ph.D., Fellow of University College, London; Professor of Physics in the Artillery College, Woolwich. London: G. Bell and Sons, Ltd. 1923. Pp. 314. 16*s*.

THE alphabet being the key to a language we cannot do better than recommend the A B C of atomic physics before its complex language is tackled. In Mr. Bertrand Russell's book we have a very good A B C—simple, lucid, and a little diverting in places. But the diversions are so cleverly introduced that they often serve the useful purpose of convincing the reader that some of the wildest flights of imagination on the part of the physicists are not really so strange after all. How wonderful a stride the modern explorer in atomic constitution has made is brought vividly home to the reader when he realises that practically the whole of the A B C of the subject has been discovered in the last 25 years. Mr. Russell's book is one that the reader may finish at a single sitting; but he will go back to this A B C to renew acquaintance with many a felicitous passage. He will no less surely want to go on with the subject after his initiation, and he can hardly do better than take up Dr. Andrade's book, which is a critical exposition of the facts and theories of atomic construction as conceived to-day, and is chiefly remarkable for the masterly way in which the matter is handled. The author knows where to go for his facts and where the fruitful theories lie, and he marshals them together, not only in order to show how wonderfully they bear each other out but also to declare their limitations. It is one of the surprises of the theories concerning energy and atom building that, while very successful within a restricted range, they become irreconcilable when called upon to coördinate the phenomena of free space as well as those of matter. It is here that Dr. Andrade holds the scales evenly before the reader, not hesitating to speak of those divergences, though, as an experimenter himself, showing the keenest pleasure in recording the close agreement that often occurs between theoretical prediction and experimental findings. Dr. Andrade has dedicated his book with modesty and grace to Sir Ernest Rutherford. We can assure him that the "presumptuous hope" he expresses in this foreword is fulfilled in the succeeding chapters of his book.

HANDBUCH DER KINDERHEILKUNDE.

Vol. I. Edited by Prof. M. VON PFAUNDLER and Prof. A. S. SCHLOSSMANN. Leipzig: F. C. W. Vogel. 1923. Pp. 962. 40*s*.

THE first volume of this work promises that when the three volumes are completed the reader will be possessed of a complete system of medicine as it applies to children. The general arrangement is good, and the scope is vast, covering every aspect of the subject from baby-linen to the chemistry of the lipines. The less abstruse portions of the book are perhaps the least attractive, illustrations such as those on p. 104 being more reminiscent of an out-of-date stores catalogue than of a modern work on medicine. On the other hand, the articles by Dr. Rudolph Neurath, of Vienna, on the physiology and pathology of puberty, and Dr. Carl Hochsinger's article on rickets will find interested readers in all countries. The bibliography given at the end of each section will be found particularly useful to those who have been latterly deprived of German literature. The book is adorned by many coloured illustrations and modern photographs which are admirably reproduced.

THE MIND IN ACTION.

A Study of Human Interests. By GEORGE H. GREEN. London: University of London Press, Ltd. 1923. Pp. 168. 3*s*. 6*d*.

THIS book explains in every-day language modern ideas about mental processes. It is peculiar inasmuch as the writer adopts the psycho-analytical view of these processes, except in regard to suggestion and auto-suggestion, where he becomes enthusiastic about Mr. Coué, and yet so thoroughly respects the taboo that sex does not find mention. A list of symbols that "stir great numbers of people" fills six lines, but the reader is left wondering what meaning they express. Some of his statements embody the uncritical acceptance of doubtful propositions, as when he says (p. 97): "The actual experience of being born . . . can be recalled in special circumstances in many cases." The matter is presented crisply and intelligibly, but the book shows little evidence of first-hand knowledge.

WHAT IS MAN?

By J. ARTHUR THOMSON. London: Methuen and Co. 1923. Pp. 244. 6*s*. 6*d*.

THE capacity of the Professor of Natural History in the University of Aberdeen for reading and thinking and writing seems to be almost limitless: in the last few years he has produced by himself a small library of very readable books with a mass of more fugitive articles to fill up odd moments. The present volume consists of a course of ten lectures on man as an organism and a social person, delivered at the invitation of the senators of the United Free Church College in Aberdeen, and intended to indicate the sort of knowledge which everyone should have about themselves. It is, as the author says, an exposition of the fundamental biological facts by a biologist who does not regard them as supreme, and the general outlook will recall Prof. Thomson's Gifford lectures on the

System of Animate Nature. He discourses in order of man's origin and early history, the development of social relations, behaviour and conduct, variability and inheritance, the struggle for existence, bodily disharmonies, and the possibilities of the future. The treatment is not profound, and he takes no very definite sides in the many controversial issues which he raises, but by references in the text and a long bibliography at the end he indicates where further discussions of the various matters may be found. The tone is mostly a cheery if rather circumspect optimism. Only on the old bugbear of the survival and multiplication of the unfit does the note of apprehension creep in. But surely, until one is quite sure, which Prof. Thomson is not, of the direction which human development is going to take—physical or spiritual—it is unnecessary to be other than cheerful about this too. There may yet be something to be said for the poor Jukes family.

HIGH BLOOD PRESSURE.

Its Variations and Control. By J. F. HALLS DALLY, M.A., M.D., B.C. Cantab., M.R.C.P. Lond. London: Wm. Heinemann (Medical Books), Ltd. 1923. Pp. 155. 10*s.* 6*d.*

THE author of this book has succeeded in getting a vast amount of information into a comparatively small space. As an introduction to the extensive literature on blood pressure the treatise is excellent, but we cannot help thinking that a more dogmatic treatment of the subject would be advisable in a manual designed for the practitioner. In the first part of the book a full and clear account of modern sphygmomanometric technique is given, special attention being paid to the auscultatory method introduced by Korotkoff. We are pleased to notice in an English text-book that the researches of Gallavardin and other French workers receive full recognition. The chapters dealing with hyperpiesis and its relation to arterial and renal disease serve to emphasise the chaotic state of modern views on this subject, rather than to simplify the problem for the busy practitioner. The author lays stress on the common mistake of relying on isolated observations of systolic pressure alone, and describes clearly the importance of the diastolic pressure in prognosis and treatment. The latter part of the book is devoted to treatment, life assurance in relation to blood pressure, and the historical aspects of the subject. A very complete bibliography is given at the end, including references to the most recent work.

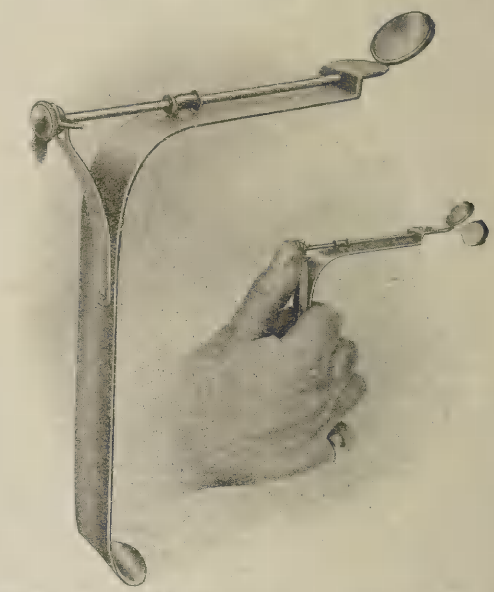
JOURNALS.

MEDICAL CLINICS OF NORTH AMERICA. Vol. VII., No. 1. London and Philadelphia: W. B. Saunders Company. Pp. 315. 55*s.*—This number, described as the Mayo Clinic Number, is entirely devoted to papers by workers in the clinic, or in the Mayo Foundation for Medical Education and Research at the Graduate School University of Minnesota.—R. M. Wilder gives a short account of the history of the discovery of insulin, its manufacture and standardisation, and a brief account of its application in the treatment of diabetic patients.—S. Franklin Adams gives a description of the food mixtures which are suitable for the treatment of diabetic patients, and a clear account of the value of the aketogenic ratio. The diabetic nomographs are printed and described.—Clifford J. Barborka describes the use of insulin in the treatment of diabetes as practised in the Mayo Clinic. The procedure in cases of severe and moderate diabetes is discussed, together with that indicated in patients with coma and those suffering from general diseases.—W. M. Boothby and Russel Wilder have estimated the effect of insulin on the basal metabolism, and conclude that it does not increase it unless the blood-sugar falls below 0·09 per cent., whereas adrenalin always increases it.—Leo L. J. Hardt and Edward G. Joseph have experimented with the kymograph under various conditions of the stomach, and the results are well worth reading.—A. H. Logan describes a successful treatment of three cases of ulcerative colitis with tr. iodine 10 drops three times a day. These three cases were completely cured, but many other cases were quite unaffected. The opinion is offered that it produces its effect by means of a general metabolic effect and not by a local effect.—Philip S. Hench records a simple method of estimating the urea in the saliva of patients with urea retention. It is only necessary to collect the saliva and titrate it with a 5 per cent. solution of mercuric chloride. It is claimed that the titration figure runs parallel with the milligrammes of urea in the blood. This method should be of use in watching patients with urea retention.—Leonard G. Rowntree discusses the Muirhead treatment for chronic Addison's disease, which consists in giving 2 to 15 minims of 1 in 100 adrenalin hypodermically twice a day, 1 c.cm. of adrenalin in salt solution twice a day per rectum, and 5 gr. dried desiccated gland three times a day by mouth. Four patients made great improvement under this regime, and the results in two others are considered as very promising.—Frederick A. Willius and Walter M. Boothby discuss the condition of the heart in a long and valuable paper on exophthalmic goitre and adenoma with hyperthyroidism.—Several other papers are also of considerable interest.

New Inventions.

A SIMPLE PHARYNGOSCOPE.

THIS instrument, which consists of a tongue depressor carrying a movable mirror, has been designed to facilitate the examination of the naso-pharynx in children and others in whom examination is difficult. In use the head of the patient is steadied by placing the left hand on the vertex, and the tongue is depressed with the instrument held in the right hand, the thumb of which then presses forward the spring controlled mirror until it passes behind the soft palate. Lateral movements of the thumb-stud cause rotation of the mirror so that a view of the whole naso-pharynx can be obtained without moving the tongue depressor. The instrument is curved in such a manner that it presses with the least force upon that portion of the tongue which, on stimulation, produces the palatal reflex.



Messrs. Phillip Harris and Co., Birmingham, are the makers.

THE LANCET.

LONDON: SATURDAY, DECEMBER 8, 1923.

DE AMICITIA.

On the evening of Thursday, Nov. 29th, over four hundred guests sat down at the Hotel Victoria, Northumberland-avenue, to celebrate the Centenary of The Lancet, and the talk was of friendship. Not merely of medical friendship, although in large measure those who were there were medical men or women, and of those who were not some admitted their youthful ambition to enter the medical profession. But of other friendships; of the increasing contact in these days between the territories of medicine and the law, of business men and women working side by side with professional men and women, of the bond between medicine and scientific thought, of intellectual alliance with other countries, not the least with France. A pleasing sense of solidarity was manifest, no one section of a motley profession preponderated; young and old were there, progressives and conservatives, seers of visions and dreamers of dreams, the scientist lying down with the empiricist. The names of those who were present are set out on another page. There were regrettable omissions of those prevented by health or urgent calls from attending, but to enumerate the names is to mention most of those who by the culture of natural gifts have attained distinction or high office in the medical world. The occasion was not one for vain-glory. Many things which were said at the gathering would be quite improper to repeat. They were little intimacies which might be passed over as kind phrases had they been other than the translation into words of an affection long manifest in deeds. For The Lancet has been for a hundred years, and will remain, a friend-made paper. Just as medicine is all-pervading, so its votaries are to be found in all classes, of all dispositions, and under all skies. And therefore the *amicitia* of which we are speaking has itself no bounds.

◆

THE PROBLEM OF RHEUMATIC DISEASE.

The one point clearly demonstrated by recent papers published on acute rheumatism, whether considered individually or collectively, is the urgent need for organised research upon the infective cause of the disease. Whatever may be the predisposing causes of rheumatism—and there are many—the fundamental ætiology of the disease remains obscure. This statement is without prejudice to the well-known work of Drs. Poynton and Paine, who believe with others that the *Diplococcus rheumaticus* is the cause of acute rheumatism. It would, in any case, not be enough to have identified merely the causative organism, for in order to understand the disease we must further know its mode of entry into and distribution among the tissues. We are still ignorant, for example, of the part played by the tonsils in rheumatic infections; this stands in marked contrast with what we know to be their significance in tuberculosis. The tubercle bacillus has been found in the tonsils and the general relation of the invading organism to the lymphatic system of the neck has been worked out in some detail; moreover, we know that most cases of cervical lymphadenitis of tuberculous origin are not commonly associated with the more generalised tuberculosis of the respiratory and digestive systems. If the tonsils are, as was recently affirmed by Dr. H. J. Starling,[1] the main portal of rheumatic infection—and, on the whole, there is more evidence in favour of the tonsil than against it as a portal of entry—it is difficult to see what prevents the causative organism from gaining access to the viscera and nervous system. Inflammation of the interposed lymphatic system has never been remarked as a feature of rheumatic infections, which indeed occur frequently enough in apparent independence of any tonsillitis.

Pending, therefore, the results of further investigation into the nature of the causative organism of rheumatic disease and its distribution in the tissues, clinical research is bound to be empirical. That is not to say that such work is not of value, but rather that each observer, since he is unable to correlate his observations with any established bacteriological picture, is compelled to enunciate some hypothesis to account for the features of the disease as they present themselves to him. The hypothesis put forward by Dr. M. O. Raven in our present issue is that, whatever the cause of the disease or the portal of its entry to the body, once an infection has been established in a child periods of restful life of many months' duration in fresh air are necessary to obviate relapse; and further, that when the heart is implicated, complete rest in bed is required until the cessation of change in the physical signs of the heart indicates that the infective stage is closed. We agree that sanatorium treatment is indeed as important in cardiovascular disease in children as in tuberculosis. To build up the resisting powers of the body and to prevent reinfection long periods of convalescence in healthy surroundings appear to be essential, and in this country convalescent homes adapted for rheumatic children and cases of early structural change in the heart are badly needed. As to the criteria of progress it is unfortunately not always so easy as Dr. Raven seems to believe to note progress in valvular disease from auscultation. The altered quality of the murmur as an index of advancing malady is open to many fallacies. But physical signs combined with general condition will probably provide sufficient information to avoid the possible danger, emphasised by certain other observers, that the heart may be put at rest for too long. Another hypothesis, already referred to, is that of Dr. Starling, who bases it upon observation of cardiac cases in adults and children. He is convinced that the tonsils are the main portal and focus of rheumatic infection and that complete enucleation of the tonsils is therefore a valuable means by which the acute attack may be aborted and further infection prevented. This thesis finds support in the important work of Dr. W. St. Lawrence,[2] of New York, who found tonsillectomy of great avail in preventing recurrence of rheumatic fever or rheumatic pains, though when chorea was present it proved a much less effective measure. It is only fair to state that against these observations stand those of Drs. G. H. Hunt and A. A. Osman,[3] who find that in a series of 144 patients those submitted to tonsillectomy showed a greater percentage of relapse than those not operated upon, whether after the first or after subsequent attacks. A third hypothesis, borne out by these last-named observations, is that recurrence is more likely to occur after a second than after a first attack.

[2] Jour. Amer. Med. Assoc., Oct. 16th, 1920, 1035–1041.

[3] Dr. G. H. Hunt and Dr. A. A. Osman: Guy's Hospital Reports, October, 1923, p. 383.

Many other theories could be mentioned, for example, that the presence of carditis increases the liability to recrudescence of infection, and that the disease is communicable. As anyone who has worked on these or similar lines will know, the collection of sufficient material and the correct ascertaining of facts contributing to support or to contradict such hypotheses must of necessity take time; the difficulty of getting accurate news of old patients is often considerable, and the interpretation of clinical observations may be contradictory. For instance, while Dr. RAVEN considers stenosis of the mitral valve to be a clinical condition which every effort should be made to prevent, Dr. STARLING regards stenosis of the aortic valve as the most favourable development in aortic cases. Incidentally, there does not seem much ground for this latter assertion. The clinical data of rheumatic disease are, indeed, plentiful enough and lie widely scattered in time and space; from whatever aspect the problem is approached, plausible and useful hypotheses can be constructed. If a case has been made out for the existence of numbers of rest homes for the reception of sufferers from rheumatic disease, it appears equally desirable that such establishments should be regarded as offering an unique opportunity for conducting organised research, not only upon the disease but upon the cardiac lesions attributable thereto. Of recent years the investigation of these lesions has yielded less fruit in the direction of prevention than in that of therapeutics. Dr. G. A. SUTHERLAND, in the address published at the front of this issue, shows clearly some of the clinical applications of our increased knowledge of the way drugs act on the diseased heart. We ought not to be satisfied with attaining greater facilities for the relief of cardiac lesions, but should strive to obtain a view of the pathological battlefield in rheumatism at least as clear as that which we now possess in the case of tuberculosis.

◆

PRISON REFORM.

THE report of Lord Justice ATKIN'S Committee on the procedure of criminal trials in which insanity is pleaded raises questions which lie on the borderland of medicine and the law. Some of these are dealt with in a special article on p. 1262. The increasing interest taken by the medical profession and the public in the subject of prison administration will be further stimulated by the recently-issued report[1] containing the latest official views on this matter. The report shows an increase of 3910 in the receptions into prison as compared with the figures for the previous year, but this increase is almost entirely accounted for by a large increase in the "debtor" receptions, most of these being committed for failure to pay arrears on maintenance and bastardy orders. In some instances this failure is due to misfortune, but many cases are those of men who, obstinately refusing to fulfil their obligations, present a problem which still awaits solution. In any case, however, the number of receptions, both absolutely, and relatively to the population, is far lower than in pre-war days, although somewhat higher than in the year immediately after the armistice.

The attitude of the Commissioners towards the officials at the several prisons shows a marked improvement. It is not so long since any expression of individual views on the part of these officials was severely checked, the result being that their reports tended towards extreme aridity and formality. To-day these reports—of which extracts appear—are much fuller and more interesting; it is realised that the expression of views by these officers, many of whom have spent their working lives in the service, can do nothing but good, even if their views happen to disagree, in certain details, from those of the Commissioners. The longest extract is that from the report of Dr. M. HAMBLIN SMITH, medical officer of Birmingham, who deals with the necessity for the intensive psychological investigation of the individual offender. This necessity is also emphasised by other medical officers. It is admitted by all that there are large groups of mentally abnormal persons which are not recognised by the existing law. Many cases of delinquency are due to mental conflict and other psychopathic conditions. And it is quite obvious that prison is a wholly unsuitable place for these cases, many of which are eminently amenable to treatment. Recognition of the existence of these psychopathies does not imply that those who suffer from them are to be allowed to do whatever they please without interference on the part of society, and public opinion will soon insist upon the provision of institutional and other arrangements for dealing with these cases on rational lines. Full psychological examination of cases before they are sentenced is of the utmost importance in other ways. Only when such examination has been made can a court possess the most essential information with respect to the case with which it has to deal, and without this information treatment must be administered entirely in the dark. It is easy to understand and to sympathise with the movement for the free granting of bail, but this implies fewer cases being medically examined before conviction. The Commissioners suggest that this problem could be solved by the provision of remand homes, quite apart from the prisons—an excellent suggestion which, however, involves a question of expense. We note with great satisfaction the establishment of a scheme for the intensive study of lads sentenced to Borstal treatment. From this scheme information of scientific value should result. Local justices do not take enough advantage of the special facilities provided for psychological examination at several prisons. This matter should be taken up by some authority which is in a position to enforce compliance with its demands. Psychological examination might also do something to prevent the futile and harmful sentences of 14 days and less which are still given in more than 25 per cent. of convicted cases. With respect to probation, the report points out the need for a high standard of quality in the probation officers. Every case placed on probation is an individual problem, just as is every case sentenced to imprisonment. Probation implies consideration of the offender's psychology, yet this fact is hardly recognised. A recent committee which investigated the probation system took no medical evidence, and did not appear to recognise that the question had a psychological side. Probation officers in this country, whatever other merits they may have, are not skilled psychologists. In some American cities this matter is better ordered, and the chief probation officer is a physician with psychological training, who is assisted by an adequate staff.

The report is, in many ways, hopeful. The paramount importance of the psychological side of penal measures is gradually becoming recognised. A scheme of education, directed by eminent experts in each locality, is being initiated. As the Commissioners say, every kind of treatment tends to produce the state of mind which it anticipates. The treatment in a well-managed prison is directed towards giving each man some sense of his responsibility, both as a member of the small prison community and as a citizen of the larger world outside. And if we work in this spirit we may look forward to the future with confidence.

---

Annotations.

"Ne quid nimis."

WORK AT THE CAIRO SCHOOL OF MEDICINE.

WE published last week two articles from the surgical department of the Royal School of Medicine in Cairo, describing work carried out in the Kasr-el-Ainy Hospital. This school is recognised by the Royal English Colleges as having a proper academic standard and a visitor is sent yearly by the Conjoint Board to inspect examinations and the general lines of medical education. Heads of departments in both school and hospital are British, working in close collaboration with Egyptian professors and assistant professors, all of whom have British diplomas and have spent some years of post-graduate study in England. The teaching is in English although there is a certain demand for a modified system of teaching in Arabic. Mr. A. B. Ibrahim writes on bilharziasis of the ureter from an experience of 100 cases observed over a period of five years. Bilharziasis of the bladder has been widely recognised, but this affection of the ureters appears to be far more dangerous and intractable in its results. Now that treatment with tartar emetic is meeting with such success, it is of the first importance to ensure early recognition of these cases of renal colic, in which the failure of radiograms to demonstrate the presence of stone leads to a suspicion of bilharziasis. Mr. A. W. Mooro's case of arterio-venous aneurysm of the neck derives its chief interest from the opportunity offered and taken of careful histology of the healed arterial wounds. Dorrance's suture, although inferior cosmetically to intra-arterial suture, healed with formation of far less fibrous tissue, and this observation may be of help to surgeons who are increasingly occupied with the suture of blood-vessels.

HERPES AND LESIONS OF THE NERVOUS SYSTEM.

THAT many acute affections of the nervous system are produced by infections is well established, and it is also probable that in the future yet others will be proved to have a like ætiology, amongst which we may cite Landry's paralysis and possibly certain cases of myelitis. The problem of the path of invasion in all such cases is one of great interest, and is still a field in which much work remains to be done. Even in such well-understood conditions as epidemic cerebro-spinal fever the route of infection is not universally agreed, although lymphatic extension via the naso-pharynx is the conventional teaching. A like path is favoured for the virus of epidemic encephalitis. Other infections—e.g., the toxin of tetanus and the virus of rabies—reach the central nervous system by following the peripheral nerve trunks, the route being clear but the intimate mechanism debated; but even in cases where the route of approach is known there is a great deal of light to be thrown upon the cause of the localisation of lesions within the central nervous system. The recent demonstration of the neurotropic affinities of the virus of herpes by Grüter, and the confirmation of this work by many investigators, but especially by Levaditi, Harvier, and Nicolau, has given us a virus which is readily manipulated and lends itself to experimentation in this direction. Inoculation into the cornea of the rabbit generally produces keratitis, with a marked tendency for the virus to spread into the nervous system, and therein to produce results akin to those produced by the virus of encephalitis, and, indeed, it is held by a majority of workers that the two infections are traceable to one and the same virus. Prof. Levaditi is himself dealing with this theme in one of the Harben Lectures to be delivered next week, in English, at the Royal Institute of Public Health in London. Recently Marinesco and Draganesco[1] have approached some of the problems we have briefly alluded to by means of experiments with this infection carried out upon rabbits. They have found that the virus ultimately attains the central nervous system whether it be inoculated by the habitual corneal route, or into a peripheral nerve or a sympathetic ganglion. Its course is demarcated by lesions of a subacute inflammatory type in the peripheral nerves and by degeneration and infiltration in the central nervous system, and is thus fairly readily followed in histological preparations. Following out this method it has been discovered that in an infection spreading up from the sciatic nerve the progress of the changes produced could be traced to the posterior root ganglia, and thence to the posterior portions of the cord, both white matter and grey. Where the inoculation was corneal, lesions were found in the choroid, the ciliary ganglion, the ophthalmic division of the fifth nerve, the Gasserian ganglion, and finally, and most intensely in their intracerebral distribution, in the sensory nucleus of the fifth nerve. The thesis of this work, therefore, is that in the case of the herpetic virus the nervous lesions which it occasions are produced by a direct invasion of the brain or cord by way of the nerve trunks, the virus travelling by the shortest available route. The distribution of the lesions within the central nervous system depend, not upon any "elective" nature of the virus, but upon the pathway by which the nervous system is approached and will, although always diffuse in some degree, constantly show especial severity in the portion of the brain or spinal cord which is first reached. The nature and intensity of the lesions in these experimental infections vary somewhat, this variation being in accord with the acuteness or chronicity of the malady.

EVOLUTION OF THE MODERN PUBLIC HEALTH CAMPAIGN.

A VIVID and fascinating history of the evolution of public health in modern life is embodied in the five pregnant chapters of Prof. C.-E. A. Winslow's recently published book.[1] In the words of Osler, he has made "an aeroplane flight over the progress of (preventive) medicine through the ages," which will amply repay study by physicians and social workers. In the first chapter the dark ages of public health are discussed, and we see contrasted the Greek and Roman care of the body, its strength, and its cleanliness, with the post-apostolic view crystallised by St. Jerome: "Who is once washed in Christ needs not to wash again." Sanitary regulations came earlier than is usually recognised, and we note with interest that Shakespeare's father was fined at Stratford-on-Avon on two occasions, once for depositing filth in a public street, and once for not keeping his gutters clean. But improvement was very slow, and so recently as the very dry summers of 1858 and 1859 the two great national reproaches were stated by William Budd to be that "India is in revolt and the Thames stinks." In the second chapter is sketched the great sanitary awakening. There were many forerunners, among whom Richard Mead, George Baker, and Captain Cook must ever hold a high place. The influence of humanitarianism and of the Wesleyan revival was very potent in expediting reform, though Chadwick's work was actuated chiefly by exceptional realisation of the economic importance of health. Prof. Winslow accepts the view that the report of the Massachusetts Sanitary Commission in 1858, which was written by Lemuel Shattuck, and was a most masterly statement of the needs and methods of reform, owed its inspiration to the writings of Chadwick and Simon. The third chapter is concerned with Pasteur and the scientific bases of prevention of disease, while the fourth chapter details more fully the triumphs of bacteriology. In the United States the first State hygienic laboratory was established at Ann Arbor in 1887–88, the first municipal public health laboratory by Dr. C. V.

Chapin in Providence in 1888. The early utilisation of bacteriology as a means of sanitary investigation owed much to the late Dr. Hermann M. Biggs. In the fifth chapter the New Public Health is discussed. This is exemplified in the child welfare movement, the various aspects of which are summarised by Prof. Winslow. Education is the keynote of this modern campaign for public health, and the importance of district nursing and of the public health nurse in this connexion need only be mentioned. The value of the educational side of anti-tuberculosis work emerges in this aspect, and with this all will agree; but there is possibly a tendency to minimise the importance of reducing massive infection by tubercle bacilli as a means of reducing the incidence of tuberculosis. We are all at times apt to forget that the amount and the frequency of exposure to infection may be reduced below the point at which disease will be produced, even when freedom from infection cannot be secured; although with this the hygienic means for raising resistance to larger doses of infection retain their importance. The problems of syphilis and of mental hygiene are also discussed; and a most important issue is raised in the statement that if medical science is to yield the high service of which it is capable, systematic medical examinations are needed, and this service medical science can by no possibility render so long as it is limited to the alleviation of the symptoms of architecturally completed disease. In Prof. Winslow's view "it is probable that, before medicine becomes truly preventive, there must be a radical alteration in the basis of payment for medical service."

DEMENTIA WHICH FOLLOWS APHASIA.

To Leonardo Bianchi must be awarded the merit of having cleared up the confusion which for some time existed in this chapter of neurology. In a series of numerous and important publications, based on a minute study of many clinical cases, he analysed the different conditions in which the intellectual deficit of the aphasic finds an expression, and he has given a clear scheme of the various and changing relations which exist between each form of speech disturbance and the mental state. In a recent article Dr. F. Vizioli,[1] of the Mental Clinic in the University of Naples, gives a lucid and succinct account of Bianchi's work in this respect. It is first of all necessary to formulate a clear definition of the term aphasia. The name is taken to mean the speech disturbance caused by a circumscribed focal lesion in a certain region of the brain, the other regions not being affected. It is recognised that if any other kind of process exists, more or less diffused, which causes cerebral disease, disturbance of the function of speech in a more or less marked degree may always ensue. But in this case the aphasia becomes a complication or symptom and it will not be possible under such conditions to determine with exactitude what value should be ascribed to it in the interpretation of the dementic syndrome which may either follow or pre-exist. The conception of clinical entity of aphasia was first materialised by Bianchi in 1887 and developed by him in numerous subsequent publications, his two principal points of view being: (1) The true aphasic is demented because of his aphasia, but the inverse proposition is not tenable since it is devoid of scientific value and logical foundation; and (2) images of words exist as well as images of things. The clinical aspect shown by individuals affected with aphasic dementia is entirely special. In the early stages during the first and second weeks of the cerebral attack which causes the aphasia there may be present more or less strong psychomotor confusion and agitation. Generally these phenomena soon become less prominent, but may reproduce themselves at more or less long intervals and with more or less marked characteristics during the further course of the disease. Under ordinary conditions it is seen that these patients show that they still possess to a large extent images of objects, that they recognise them and their uses. If by gestures they can be made to understand a command, they perform it with sufficient precision. They rarely commit foolish actions and retain good relations with their relatives. Sometimes they have a vague consciousness of their condition and show resentment about it, but more often they remain impassively stupid and smiling. Their behaviour is usually good, and in hospital they are often eager to help in small every day duties. They know the doctors from the attendants and other patients, and are deferential to those whom they know to hold superior positions. In aphasic dementia we have therefore a distinct clinical entity which no one can deny without denying the evidence of facts or artificially misconceiving the results of observation. The main conception which dominates the mechanism of production of the demented state is that the sensory aphasic is demented because he is aphasic, whereas the inverse formula is erroneous. Three types may be distinguished according to the site of the cerebral lesion: (1) In some cases it follows a lesion of the inferior parietal lobe, and especially when this lesion affects well-educated individuals who by much study have accumulated a vast patrimony of culture which the lesion suddenly annuls. Such cases are not numerous and are recognised because other symptoms which reveal the localisation are added to the demented element. (2) Most frequently aphasic dementia follows a lesion of the auditory zone which is of the highest physiological importance in the complex mechanism of speech. (3) The third group is where there is paresis of the auditory centre through the lesion of the tracts of conduction and association. Considering the merit due to Prof. Bianchi of having isolated this clinical form and of having analysed the different conditions and the psycho-pathological mechanism by which the intellectual deficit of the aphasic becomes established and developed, Dr. Vizioli suggests that this mental condition should be henceforth known under the name of "Bianchi's disease." As Bianchi himself says, "the destruction of the region of the brain which has the function of constructing the images of words, of preserving and reproducing them as symbols of things in the external world, and their relations in the formation and expression of thought, implies a constant and profound intellectual deficit which is true dementia, even though the individuals who are affected with it are able to show a well-balanced and quiet demeanour and appear to recognise and even criticise the world which environs them."

THE BONE MARROW AFTER SPLENECTOMY.

In a study of the changes that take place in the marrow after splenectomy Ernest M. Johnstone[1] has reached somewhat different conclusions from those arrived at by previous workers, notably Pearce and Krumbhaar.[2] The latter authors failed to find early changes in the marrow that would account for the phenomena, clinically observed, that the most severe stage of anæmia and recovery therefrom occurs during the first six months after splenectomy. They concluded that the late changes found—namely, hyperplasia occurring 6, 12, and 18 months after removal of the spleen—cannot be explained as compensatory to the anæmia following this operation. Contrary to these findings, Johnstone has found definite early changes in the marrow. He attributes the difference between his results and those of other workers to a fundamental difference in the method of experimental control. Former observers used the marrow of one animal to control the changes of another, whereas Johnstone has shown that the marrows from different normal animals vary very considerably, and therefore he controlled his post-splenectomy changes by an examination of a specimen removed from the same animal before the operation. Further controls were obtained from non-splenectomised animals which were subjected to similar conditions as the splenectomised, even to the extent of opening the abdomen, drawing out the spleen, submitting it to the same amount of trauma as would be given were it removed, but replacing it in its place and closing the wound. Johnstone found that changes occurred earlier in the rib marrow than in the central third of the femur (the site chosen by other workers), and he therefore made his observations on the former bones.

---

[1] Papers from the Mayo Foundation, vol. ii., 1921–22.

[2] The Spleen and Anæmia: Experimental and Clinical Studies. Philadelphia: J. B. Lippincott Co. 1918.

In analysing his results he noted the changes that took place as follows: (1) Changes in the marrow itself—namely, erythrogenesis, leucogenesis, vascularity, and density of the marrow cells; (2) changes in the blood—namely, hæmoglobin content, erythrocyte, leucocyte, and differential count; and (3) changes in the condition of the animal, such as weight, general appearance, and any factor which might, even slightly, influence the marrow. Five series of experiments were carried out, of which the first four were unsatisfactory in not attaining exact experimental control, and are therefore not reported in detail. The fifth series consisted of (*a*) 14 dogs, eight splenectomised, and six non-splenectomised, from which specimens of marrow from the ribs were taken at frequent intervals, the operations being carried out under ether anæsthesia with sterile technique; and (*b*) four dogs, two splenectomised and two non-splenectomised, treated as in (*a*), but with the substitution of cocaine anæsthesia for ether. In order to obtain the marrow specimens a piece of rib 4 cm. long was removed from a point midway between the spine and sternum. The first specimen, removed before splenectomy, served as a control for subsequent observations on the same animal after splenectomy. The non-splenectomised dogs in both series received exactly the same treatment, including removal of portions of the ribs and the abdominal operation, but the spleen was returned to the abdomen. In this way many specimens (up to nine) were removed from the same animal at intervals of a few weeks to several months during a period of 54 weeks' observation. Thus each splenectomised dog was controlled by a specimen taken before the removal of the spleen, and by another dog subjected to exactly the same procedure at the same time. Before each operation the general condition of the animal was noted and the blood count examined. At the end of the experiment the animals were killed and necropsy performed to ensure that no other disease or factor was present that could have influenced the observations. Animals suffering from any complication were removed from the series.

Summarising these results Johnstone found that (*a*) the erythrogenetic activity was increased after a latent period of about four weeks. It reached its maximum intensity at about the twelfth week, remained at that level for about 12 weeks, and then decreased until about ten weeks later it reached a degree slightly above the normal before splenectomy, at which level it remained. Coincidently with this sequence of events, the hæmoglobin, red cell count, and weight of the animal first diminished with the development of anæmia, and only slowly rose again until they reached or exceeded a normal level. The vascularity and density of the marrow cells showed changes running parallel with the erythrogenetic activity. (*b*) The leucogenetic activity showed a marked rise in the first two to three weeks, but rapidly sank to the normal or below it. These changes were, however, inconstant. Concurrently the blood showed a parallel leucocytosis. From these results it appears that the increased erythrogenesis occurs some time before the reduction of the anæmia, and indicates that "whatever destructive agent becomes active after the removal of the spleen, it is so potent that its effect can be compensated only by prolonged hyperactivity and hyperplasia of the marrow." In discussing the relation of the marrow changes to the removal of the spleen and the subsequent anæmia, Johnstone mentions the various theories that have been advanced, such as the presence of a hæmolysin or the absence of an anti-hæmolytic body, a delayed release from the cells manufactured in the marrow, the effect of ether anæsthesia, and so on; but he comes to the conclusion that the hypertrophy and hyperplasia in the marrow is "probably secondary and compensatory to the anæmia that follows removal of the normal spleen, thus representing a physiologic response to a demand for more blood cells. It may have no relation to the absence of the spleen. The persistence of this marrow reaction, which far exceeds the duration of the post-splenectomy anæmia, may likewise be an expression of the law of regeneration in excess."

CHRONIC GLANDERS IN MAN.

Owing to the rarity of glanders in man, errors in diagnosis are apt to be made. Dr. H. Schwarz, of Troppau in Silesia, who records[1] a case in a soldier, aged 27, which proved fatal after 21 months' illness, illustrates the rarity of human glanders by the fact that during the period 1876–86 there were only 20 known cases in the whole of Prussia. During the late war, when there was for a time a considerable increase in glanders among horses, no epidemic occurred among human beings. According to Lühr's estimate, during the war there were only about 50 human cases, and these were mainly due to laboratory infections from handling cultures of glanders bacilli. Manipulation of the blood of infected animals apparently never gave rise to any case. Veterinary surgeons are occasionally infected in the performance of autopsies, but the attendants of animals suffering from the disease run the greatest risk. The not infrequent occurrence of joint swellings in the course of chronic glanders may lead to the erroneous diagnosis of polyarthritis. Acute glanders is liable to be mistaken for typhoid fever, septicæmia, or erysipelas, while chronic glanders, as in Schwarz's case, may be diagnosed as tuberculosis or syphilis. The mortality from chronic glanders is 50 per cent. (Jochmann). As regards treatment, Lühr and his collaborators, who carried out systematic investigations on a large number of horses during the war, employed seven different varieties of salvarsan, dyes such as methylene-blue, copper compounds, preparations of iodine and mercury, quinine, and other drugs. Most of these had no effect, though a combination of mercury and potassium iodide was encouraging. Protein-therapy, the use of serum, and treatment with glanders bacilli were also fruitless, and a specific cure for the disease has not yet been found.

FISH VENOMS.

Among the poisons belonging to the mineral, vegetable, and animal kingdoms there are few of which so little is known as the poisons contained in or excreted by fish. This is the more strange as a good deal of research has been carried out in this field, and Dr. H. Muir Evans, of Lowestoft, has for many years been engaged[2] in painstaking investigations into the nature of the defensive venoms of fish. His most recent work on the defensive spines of fishes, living and fossil, and the glandular structure in connexion therewith, with observations on the nature of fish venoms, published in the Philosophical Transactions of the Royal Society of London (Series B, Vol. 212, pp. 1–33) is largely concerned with the action of the venoms of *Trachinus draco* (the greater weever) and *Acanthias vulgaris* (the spiny dog-fish). Dr. Evans has supplemented his laboratory investigations with the clinical research for which a fishing port like Lowestoft provides ample opportunities, and he has come to the conclusion that the venom of *Trachinus draco* has both a neurotoxic and a hæmolytic action, the latter characteristic being the most important. The pain of a weever sting is of a burning, stabbing character and may be severe enough to drive a man mad. Smacksmen have told Dr. Evans that if a live weever is thrown overboard and is seized by a gull it falls into the sea as if struck dead. A rare complication is the appearance of hæmorrhagic patches. If the sting is not treated, the pain may last for hours or throughout the day, and on account of the importance of poisoning by fish venoms among fishermen at sea, Dr. Evans is of the opinion that our smacks and drifters should be obliged to carry a simple outfit for the treatment of such cases. The most useful method is to inject into the puncture a few minims of a 5 per cent. solution of permanganate of potash, and a simple outfit, consisting of a small glass hypodermic syringe, rustless needles, and some small ampoules containing a solution of permanganate of potash, would cost little and might prevent much suffering. Two patients treated by Dr. Evans in this manner obtained immediate relief from the pain, and there was no subsequent inflammation or gangrene. It would be interesting to learn if the fish venom introduced into the human body parenterally by a stab has any connexion with the symptoms of poisoning induced by eating certain fish. There is a possibility that in both forms of poisoning the suprarenals may be involved, and in this connexion it is instructive to note that a Danish physician has recently recorded two cases of severe asthma following a large meal of uncooked mussels. In both cases the most distressing dyspnœa was associated with cutaneous phenomena—a scarlatiniform rash in one case, and severe itching in the other. In both cases the hypodermic injection of a little adrenalin had a most dramatic effect, normal respiration being restored within two minutes.

---

[2] See also The Lancet, 1921, i., 517.

The pathological action of venoms will probably be unravelled by observations on the lower forms of animal life. Mussel poisoning may give rise to various clinical types—an exanthematous type, with itching and a rash, a gastro-intestinal type, and a paralytic type. In 1907 Richet obtained from the mussel (*Mytilus edilis*) a toxic substance analogous to the actino-congestine which he had previously extracted from sea anemones. Mytilo-congestine causes diarrhœa, vomiting, prostration, and, most significant of all, a fall of the arterial blood pressure. The necropsy shows intense hæmorrhagic congestion of the mucous membranes. Actino-congestine produces a similar clinical picture. Closely allied to the latter venom is meduso congestine obtained from the jelly-fish (*Rhizostoma cuvieri*), which causes local irritation and œdema, and in some cases intense dyspnœa, prostration, and severe diarrhœa in rabbits and guinea-pigs. The post-mortem findings include œdema of the lungs, visceral hæmorrhages, and congestion of the liver, kidneys, and intestine. But the most significant lesions are those of the suprarenal capsules which are engorged with dark blood. It is interesting to note that the venom of the weever also causes intense visceral congestion and internal hæmorrhages. It is probable that the dried venom of the jelly-fish is responsible for the frequent attacks of intense coryza and even asthma observed among the men when nets are mended after the summer drift fishing. These are but a few of the many points of great interest raised by the researches of Dr. Evans and others, and it is to be hoped that future investigations will add much to what we already know of a fascinating subject.

THE HEART IN DIPHTHERIA.

After a review of the literature, in which she shows that there is by no means unanimity of opinion as to the cause of cardiac failure in diphtheria, Dr. Mathilde Loth,[1] of the Department of Pathology and Bacteriology of Yale University, describes her own observations on the heart in diphtheria, which consisted chiefly of (1) investigations of human cases coming to autopsy and (2) observations on the effect of diphtheria toxin on the guinea-pig heart. Physical examination of the cases which came to autopsy showed enlargement of the heart to percussion, feeble heart sounds, and gallop rhythm. The chief gross pathological finding was dilatation of the right side of the heart. On histological examination in only one out of 19 cases was definite myocarditis noted. The principal histological lesions were more or less cloudy swelling and fat accumulation with slight increase in the number of interstitial cells, which were mostly mononuclears. Comparative studies of the heart in cases in which death occurred from some infection other than diphtheria and a third group in which the heart was presumably normal showed that the differences between the three groups were quantitative rather than qualitative. There was no sharp line between the normal and abnormal, and no clear-cut difference could be detected in the hearts from diphtheria cases and those from other types of infection. Injection of lethal or sub-lethal doses of diphtheria toxin into guinea-pigs produced degenerative changes in the heart muscle similar to those seen in the human heart after diphtheria, but a true inflammatory reaction was not produced.

THE FAR EASTERN ASSOCIATION OF TROPICAL MEDICINE.

The Fifth Congress of the Far Eastern Association of Tropical Medicine was held in Singapore from Sept. 3rd to 17th last under the Presidency of Dr. A. L. Hoops, principal civil medical officer of the Straits Settlements. From the formidable list of 78 scientific papers submitted at this Congress, as well as from the large number of medical men of many nationalities who attended, we may gather that much important work was done. Accompanying the official report are three scientific contributions which have already been printed. Dr. A. T. Stanton, in discussing the control of beri-beri in the Far East, considers that the over-milling of rice is the chief factor in the production of this disease; and this vitamin deficiency theory is supported, not only by the results of animal experiments, but also by observations on outbreaks of the human disease. He further considers that the theory is supported by the result of preventive measures undertaken during the past ten years, and by the effects of food control on the incidence of the disease in Malaya. For the effective control of beri-beri the first essential is to ensure that a supply of under-milled rice is available as an ordinary market produce, and that it is sold at a price which enables it to compete with the over-milled variety. This should be accomplished by taxes on over-milled rice, inasmuch as an international convention to prohibit its production seems at present impracticable. On the whole he believes that education and propaganda methods amongst employers of labour and other classes in the community are the most effective means of combating this disease. W. A. Sawyer made a contribution on the advantages of international organisation for control of disease, with special reference to hookwork disease and beri-beri. He also advocates some international action with reference to the taxing of unsuitable rice. Apparently in Australia such a tax has long been in existence, having been instituted primarily to protect the milling industry in that country. With reference to hookworm disease, the campaign at present being conducted in Australia is described. An admirable review of recent work upon vitamins, which contains a few original observations, is contributed by M. Barrowcliff. It is hoped that the full Transactions, comprising nearly all the communications, in two volumes, will be published before the middle of 1924.

We regret to announce the death of the well-known physiologist, Prof. Robert Tigerstedt, at Helsingfors on Dec. 2nd, in his seventieth year.

Applications are invited for the office of Milroy Lecturer for 1925. The lectures have to deal with State medicine or public health, and carry an honorarium of 60 guineas. Suggestions are kept in print for the guidance of lecturers.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XLVIII.—THE TREATMENT OF PYELITIS.

THERE are many phases and varieties of inflammation of the renal pelvis, and the important preliminary to treatment is correct diagnosis. Cases in which the use of the cystoscope and the ureteral catheter are required are best treated by the urologist. Pyelitis may complicate pre-existing disease of the urinary tract, or may develop in a urinary tract free from disease. In the former case the infection is ascending, in the latter the source of infection lies usually in the bowel (colitis, chronic constipation, appendicitis, chronic dysentery, piles) or gall-bladder (gall-stones, cholecystitis), and the infection is hæmatogenous. Pyelitis is of special importance in infants and in pregnant women. The infection is most commonly due to the *B. coli communis*, present in pure culture. Pyelitis may be acute, chronic, recurrent, and quiescent or "silent."

The Acute Condition.

In acute uncomplicated pyelitis the onset is sudden, and the patient, who is seriously ill, is confined to bed and to the care of a nurse. A smart purge is administered either in the form of a pill containing mercury, colocynth, and hyoscyamus, or of a large dose of castor oil, followed by a saline. There has usually been a period of constipation or of diarrhœa before the onset of the attack, and during the acute stage of the pyelitis there is atony and distension of the large bowel, partly from the adjacent inflammation in the renal pelvis and partly from the fluid diet. After the purge a daily action should be ensured by means of senna, cascara, or some other vegetable laxative. Salines are unsuitable for continued use in these cases on account of the distension of the bowel they produce. A daily enema (soap and water) may be necessary, and washing the large bowel and the occasional use of a rectal tube may give much relief. There is often severe pain in the kidney, and there may be renal colic from descending ureteritis. Small doses of morphia may be necessary. In uncomplicated pyelitis the infection is unilateral, and since it does not involve the kidney there need be no hesitation, on account of the renal function, in giving morphia for pain. But the effect of the morphia on the bowel will limit its use to the most severe cases of pain. Hot fomentations, turpentine stupes, antiphlogistine, or linseed poultices will give much relief.

Diuretics are used in all cases. A diuretic water such as Vittel, Contrexéville, or Vichy, should be given and a definite quantity, such as one bottle (1 litre) or one and a half bottles, each 24 hours, prescribed. The water may be slightly warmed. Other diuretics may be used. Buchu tea, made by adding a tablespoonful of the dry leaves to a pint of boiling water in a teapot, and infusing for 15 minutes, and drunk hot, two pints in 24 hours, is a powerful diuretic, and should be used if the patient does not rebel on account of the taste. Parsley tea may also be prepared.

Alkaline treatment is the most effectual in the majority of cases of acute pyelitis, for the reaction of the urine is mostly strongly acid and the infection a pure culture of *B. coli*. Sod. bicarb. is the most powerful alkaliniser of the urine, but citrate and acetate of potash are efficient and are less unpalatable. The dose should commence with 10 gr. four-hourly until the urine is neutral or slightly alkaline, when the quantity is reduced to 10 gr. t.d.s., the reaction of the urine being kept neutral or slightly alkaline by varying the dose. The alkaline, combined with diuretic treatment, should continue until the temperature falls and the local symptoms subside.

Urinary Antiseptic Treatment.—The urinary antiseptics are the formaldehyde series (hexamine, urotropin, helmitol, &c.), salol, and boric acid. Boric acid has a moderate antiseptic action in the urine but upsets the digestion, and in acute cases is better avoided. Salol is most useful in cases with prominent bowel symptoms. It may be prescribed alone (10 gr., in cachet, t.d.s.) or combined with mercury and naphthol. Salol, 10 gr.; β naphthol, 5 gr.; and pulv. hydrarg. c. creta, 2 gr., is a useful combination.

The formaldehyde series of urinary antiseptics gives the most powerful antiseptic action in the urine. Hexamine (or urotropin) is absorbed, circulates in the blood-stream and is excreted by the kidneys, and when it comes in contact with the acid urine is split and formaldehyde given off. Hexamine should be taken in a large draught of water when the stomach is empty, so as to avoid the action of the acid gastric juice. It should not be combined with an acid (sodium acid phosphate), as formaldehyde is liberated in the mixture and indigestion will probably result. If the urine is neutral or alkaline, an acidifying drug should be given, such as sodium acid phosphate (30 gr. t.d.s.), and the dose increased until the urine becomes acid. Sodium acid phosphate should be given after food, but sodium benzoate may be combined with hexamine. The antiseptic and alkaline treatments are alternative and cannot be given together. The alkaline treatment should first be tried.

Diet should be mainly fluid, but if the patient can take Benger's or milk-pudding, the flatulence caused by excessive quantities of fluid may be avoided. Tea may be given, but not coffee; alcohol only for definite collapse or extreme weakness.

Vaccines are rarely of use in acute pyelitis, but during the acute stage an autogenous vaccine should be prepared ready for use when the attack is waning.

Relapses.—The patient or his friends must be warned of the common occurrence of relapses, especially on first getting out of bed or going downstairs. The patient should therefore be confined to bed for seven or ten days after the symptoms have disappeared and the temperature is normal, and the return to normal life should be gradual. In the pyelitis of infancy the high temperature may necessitate tepid or cold water sponging. In the pyelitis of pregnancy the uterus need only very rarely be emptied; catheterisation of the ureter on the affected side with lavage of the renal pelvis has, in some cases, a rapidly beneficial effect. This method has its risks in acute pyelitis, and should only be adopted after careful consideration.

In acute pyelitis constant watch must be kept for the enlargement of the kidney, which will indicate pyelonephritis, or if the urine suddenly clears, the pain increases, and the temperature assumes a swinging character, pyonephrosis has developed. In these cases operation, either nephrotomy or nephrectomy, will probably be required.

Ascending Pyelitis.—In acute pyelitis (ascending pyelitis), which is secondary to infection of the lower urinary tract, either recently produced by catheter, sound, or operation, or of long standing, the general treatment is identical with that already outlined. Surgical interference in the lower urinary tract is reduced to a minimum. If a stricture is being dilated, the passage of instruments is at once stopped; if a course of bladder washing for cystitis is in progress, this is discontinued. But where obstruction is present, provision must be made for drainage of the bladder. In an enlarged prostate, requiring the catheter, the instrument may be tied in the urethra; or if there are difficulties in the way of this or the cystitis is acute, a rapid suprapubic cystotomy with the introduction of a large tube (not a small self-retaining catheter) will be the best procedure. The object should be to retain free drainage with the minimum of interference.

Chronic, Relapsing, and Quiescent Pyelitis.

In chronic, relapsing, and quiescent pyelitis there is often difficulty in diagnosis. The local symptoms (pain and tenderness) may be slight or even entirely wanting. The symptoms are usually those of chronic cystitis, and the diagnosis is made by means of the cystoscope and ureteric catheter. In these cases washing of the bladder, while it gives temporary relief from symptoms, has no effect on the source of the infection, and if too vigorously carried out, may actually be the exciting factor of an attack of pyelitis. Either antiseptic treatment or alkaline treatment may be tried, remembering that the antiseptic treatment is an attempt to destroy the bacteria, while the alkaline treatment only neutralises the acid toxin. The treatment is likely to be prolonged, and it is much better to interrupt it from time to time than to give a fixed dose of hexamine for an indefinite period. The patient should be warned of the chronic nature of the complaint, and the medicine prescribed in courses of four weeks at a time. During the course the dosage and the reaction of the urine should frequently come under review. The usual dose of 10 gr. of hexamine three times daily may cause irritation in some patients when the urine is highly acid. In this case the dose should be reduced to 5 or 3 gr., and if any acidifying drug (sodium acid phosphate) is being given, it should be omitted. In other cases the dosage may be increased to 12 or 15 gr. three times daily. Beyond this there is usually increased bladder irritation. The reaction of the urine must be definitely acid. If the urine is alkaline, acidifying drugs must be given with the precautions already mentioned. It is often helpful to give alternate courses of a month of the alkaline and the antiseptic treatment. Hyoscyamus, belladonna, and small doses of opium are useful for quieting bladder spasm and sandalwood oil is soothing to the mucous membrane.

Vaccine-Therapy.—The results obtained by vaccines in chronic pyelitis due to *B. coli* are often disappointing, but undoubted benefit often follows their use. The usual method is to commence with small doses of 3 or 5 millions of autogenous vaccine, and rise slowly by weekly injections to as high as 300 or 500 millions, reducing the dosage if a pronounced reaction follows an injection. Here again the value of repeated short courses is, I believe, greater than that of injections continued for an indefinite period.

Lavage of the Renal Pelvis.—In chronic and relapsing pyelitis, lavage of the renal pelvis is of great service. It is a method which, in the hands of the expert, is easy and carries little risk, but in the hands of the inexperienced is dangerous. It consists in introducing a fine catheter through the cystoscope along the ureter into the renal pelvis and injecting, by means of a small syringe, a small quantity of mild antiseptic into the renal pelvis, and allowing it to flow out. This injection is repeated a number of times, and the pelvis is finally emptied and the catheter withdrawn. No general anæsthetic is required unless in the most nervous of patients. After the lavage the patient should rest for a day in bed, unless well accustomed to instrumental manipulation when a rest of one or two hours may be sufficient. The fluids I most frequently use are silver nitrate solution (1 in 15,000), collosol argentum (½ or ¼ strength), oxycyanide of mercury (1 in 10,000). A course of six injections at fortnightly intervals should be tried, general treatment not being interrupted. Renal lavage is frequently but by no means invariably successful in curing the infection; distressing bladder symptoms may disappear, while bacteria persist in the urine, and the patient should be warned of the probability of a recurrence of symptoms. The presence of a quiescent calculus in, or dilatation of the renal pelvis, may cause persistence of pyelitis in spite of treatment. In a case of chronic or relapsing pyelitis the original source of the infection—for example, chronic constipation, colitis, chronic appendicitis, piles, diverticulitis, cholecystitis, and gall-stones—should be searched for and carefully treated, and cases cured after prolonged treatment may relapse from a reinfection from the bowel. On the other hand, I have met with pyelitis which followed too energetic washing of the large bowel in colitis. Treatment of these primary sources of infection should always form part of the treatment of pyelitis.

John Thomson-Walker, F.R.C.S.,
Senior Urologist, King's College Hospital; Surgeon,

THE GENERAL MEDICAL COUNCIL.

Penal Cases.

The winter session of the General Medical Council opened on Nov. 27th; Sir Donald MacAlister presided. His address appeared in The Lancet of Dec. 1st. Nineteen penal cases came before the Council during the session. The cases were heard in public; the Council deliberated upon them in camera, and the decisions were publicly announced as usual. Two of these cases were forwarded by the Dental Board with the findings of the latter body. Four medical cases had been adjourned from previous sessions of the Council. Four names were erased from the Medical Register, and two names were erased from the Dentists Register. Three medical cases were withdrawn for various reasons; the remaining cases were briefly as follows:—

Tuesday, Nov. 27th.

The Case of Ernest Mayer.—This case was adjourned from the May–June session. E. Mayer (or E. Mayer Neville), registered as of Tynewydd Villa, Treherbert, Glam., was then found to have permitted posters printed at his expense to be exhibited at a colliery and in houses, inviting workmen desirous of choosing himself as their panel doctor to do so, and giving directions as to the means of effecting a transfer. A second charge, of giving implied or expressed consent to house-to-house canvassing carried out with the same intention, was found to be not proved. Testimonials with regard to Dr. Mayer's conduct in the interval were placed before the Council, and Dr. Mayer repeated his previously expressed regret. The Council did not see fit to direct erasure of his name from the Medical Register.

The Case of Patrick Joseph Honan.—P. J. Honan, registered as of 2, Glandore-park, Antrim-road, Belfast, had been convicted at the Surrey Assizes, held at Guildford on July 5th, 1923, of a felony—namely, of using a curette or other instrument with intent to procure a miscarriage, and had been sentenced to 18 months' imprisonment with hard labour. Dr. Honan attended in custody, and was represented by Mr. Conway, solicitor. It appeared that the relation between the practitioner and his patient was personal, not professional; at the assizes Mr. Justice Avory had stated that he was satisfied that the accused was not carrying on practice in the procuring of miscarriage for trade or reward. The woman in question had been seriously ill following the operation, but had recovered. The Council directed that the name of Patrick Joseph Honan be erased from the Medical Register.

The Case of James Reidy.—This case was adjourned from the November session, 1922. James Reidy, registered as of Gardenfield, Newcastle West, Co. Limerick, had been several times convicted between 1920 and 1922 of being drunk and incapable or disorderly. Letters of recommendation concerning his behaviour in the interval were read, and Mr. Reidy renewed his previously made undertaking to refrain from drink. The Council did not see fit to erase his name from the Medical Register.

The Case of David Charles Williams.—This case was adjourned from the May–June session. D. C. Williams, registered as of Brynfedwen, Treherbert, Glam., was found to have been guilty of a breach of the Council's notice with regard to "covering," having permitted an unregistered person (his "dispensary attendant") to practise in his presence as if he were registered in the Dentists Register. Dr. Williams had supported his assistant's claim to be so registered by a certificate in which he stated that the said assistant had performed "all operations usually entrusted to dentists." The Dental Board, however, had found that the assistant could claim only the status of a mechanic, and had not admitted his name to the Register. The terms of Dr. Williams's certificate, therefore, laid him open to a charge of covering. The Council accepted, in place of the usual letters from members of the medical profession, statutory declarations from Dr. Williams and his dispensary attendant as to the latter's employment in the interval. The Council accepted Dr. Williams's assurances as to his desire to comply with every regulation called for by a high standard of professional conduct, and did not see fit to erase his name from the Register.

The Case of John Herbert Cecil Grene.—J. H. C. Grene, registered as of Bryn Issa, Bridge-street, Wrexham, was convicted, at the Broxton (Chester) Petty Sessions on May 29th, 1923, of driving a motor-car in a dangerous manner, and of being drunk in charge of the car, and fined on each count, his licence also being endorsed. The Council had in this case taken the unusual course of acting on a solitary conviction in view of the increasingly serious view taken by the law of drunkenness when in charge of a car. Dr. Grene maintained that he was not drunk. Letters from medical men and others were read testifying to Dr. Grene's character. Relying on his promise to abstain from alcohol in the future, the Council did not see fit to erase his name from the Medical Register.

The Case of Thomas Hill.—T. Hill, registered as of Derwen Deg, Pontlottyn, Glam., was convicted on August 14th, 1923, of being drunk in charge of a motor-car, and sentenced to one month's imprisonment in the second division. Dr. Hill was represented by Mr. G. O. Slade, his counsel, who stated that he considered the Council had no jurisdiction in this case, as the word "misdemeanour" in Section 29 of the Medical Act, in his submission, related only to indictable misdemeanours. After consultation with the Legal Assessor, the President overruled the objection. Dr. Hill was understood to have pleaded guilty at the police court on the advice of a solicitor, who counselled him to take this course in order to avoid publicity. He gave his word of honour that such a thing would not occur again. Relying on this promise, the Council did not see fit to erase Dr. Hill's name from the Register.

WEDNESDAY, NOV. 28TH.

The Case of Charles Gilroy King.—C. G. King, registered as of 1425, Pollokshaws-road, Glasgow, was convicted at the sheriff court of Lanarkshire, at Glasgow, on June 21st, 1922, of procuring drugs from a chemist and failing to supply prescriptions and to enter particulars of the said drugs or any portion thereof in a day-book or register kept for the purpose, contrary to the Dangerous Drugs Act, 1920, and regulations made thereunder, and fined £50 or 30 days' imprisonment, and convicted at the same court on June 25th, 1923, on a similar charge, receiving a similar sentence. These prosecutions had been undertaken by the Home Office, whose medical inspector had brought the facts to light. Part of the drugs procured had been dispensed to patients in an ordinary manner, but most of the supply went to Dr. King's wife, who was an addict; it appeared that Dr. King was completely under his wife's influence, and in spite of promises made after the first visit of the Home Office medical inspector, no better care was taken in respect of the registering of drugs. The Home Office authorisation under the Dangerous Drugs Act had been withdrawn from Dr. King, but no question arose as to his having attempted to traffick in these drugs. The Council considered that Dr. King had not fully apprehended his responsibilities under the Dangerous Drugs Act; judgment was postponed for 12 months, with the usual proviso as to unexceptionable behaviour in the interval.

The Case of George Denholm Darlington.—G. D. Darlington, registered as c/o Royal Bank, Hunter-square, Edinburgh, had been three times convicted at the Edinburgh police-court, between 1919 and 1923, of being drunk and incapable, and was twice fined. Mr. Darlington attended and addressed the Council on his own behalf. The Council directed that his name be erased from the Medical Register.

The Case of William Mortimer Sheen.—W. M. Sheen, registered as of Wycliffe House, Highfield-road, Saltley, Birmingham, was charged with having knowingly enabled a woman not certified under the Midwives Acts, 1902 and 1918, to attend 17 cases of women in childbirth under cover or pretence that such women were attended to or to be attended by him or under his direction, and with having in many of these cases signed maternity benefit certificates and given notifications of birth, thereby enabling the woman in question to practise as though she were certified under the Acts. The complainants were the Birmingham City Council. Dr. Sheen was accompanied by Mr. J. P. Eddy, his counsel, who stated on behalf of his client that the latter, who had a panel of some 3000 patients, was grossly overworked at the time of the events in question, and was unwell. He stated that the Midwives Act, 1902, had never been judicially construed until April of this year, and few medical men knew its real meaning; but that, having regard to the recent decision in April last, his client now saw that he had not acted correctly, and desired to express his great regret. The Council found Dr. Sheen to have been guilty of infamous conduct in a professional respect, and directed that his name be erased from the Medical Register.

The Case of John Christie Forbes.—J. C. Forbes, registered as of 40, Mayfield-road, Edinburgh, was charged with having permitted his female clerk to sign in his name and to issue certificates required for National Health Insurance purposes, in which certificates it was stated that he had examined the patient, although in many cases he had not done so; and with having permitted the clerk on several occasions to sign and issue orders for prescriptions for an insured person. Dr. Forbes was represented by Mr. W. G. Manson, his counsel, who submitted that the action of his client did not amount to infamous conduct in a professional respect; that no moral turpitude was attributable to Dr. Forbes, who had merely committed a technical breach of the National Insurance Acts, which he much regretted, and which would never occur again. The Council found that the facts alleged against Dr. Forbes had been proved to their satisfaction, and that the certificates in question were given in a lax and careless manner, and were in effect inaccurate, misleading, and improper. The President emphasised the gravity of laxity in the giving of such certificates, and announced that the Council had decided to postpone pronouncing judgment until the May session, 1924, with the usual proviso as to correct behaviour in the interval.

THURSDAY, NOV. 29TH.

The Case of Walter Wiglesworth.—W. Wiglesworth, registered as of Mendip Lodge, Farncombe, Surrey, had been three times convicted at the Westminster, Bow-street, and Marylebone police-courts between 1913 and 1923 of being drunk and disorderly, and fined. Dr. Wiglesworth addressed the Council on his own behalf, stating that he very seldom drank stimulants, that very little alcohol excited him, and that he had lately had serious anxiety in the shape of domestic bereavement and financial loss. He gave an assurance that he had determined to refrain from alcohol for the rest of his life. The President, in announcing the decision of the Council, pointed out the danger of the habit indicated by the convictions, and announced that the Council, accepting Dr. Wiglesworth's assurance, did not direct his name to be erased from the Medical Register.

The Case of John Richard Griffith.—J. R. Griffith, registered as of Argoed, Mon., was charged with having employed as his assistant one Frederick A. Cotton in connexion with his practice, a person not qualified or registered under the Medical Acts, and with having knowingly allowed this assistant to attend, on his behalf, and treat patients in respect of matters requiring professional discretion or skill, and to sign and issue on his behalf insurance medical certificates. The complainants were the London and Counties Medical Protection Society, represented by Mr. Carthew. Dr. Griffith attended, and was defended by Mr. Bernard Campion, K.C., and Mr. A. T. James. Mr. Carthew stated that the principal witness for the complainants, Mr. Cotton, Griffith's assistant, had died the day after making his statutory declaration. Mr. Campion said that Dr. Griffith's case depended largely on the cross-examination of that witness, but that he would not raise any technical objection to the case proceeding. Mr. Cotton's declaration was then read. It stated that Mr. Cotton had been a dispenser for 12 years, and was engaged by Dr. Griffith between October, 1919, and April, 1923. He alleged that soon after entering his service Dr. Griffith asked him to see patients on his behalf, and presently he was accustomed to examine patients and to sign certificates in Dr. Griffith's name. Dr. Griffith had an insurance list of some 1300 persons, as well as a private practice. The majority of the patients believed him (Mr. Cotton) to be a medical man. Various witnesses were called in support of this declaration, and some were cross-examined. Dr. Griffith, in evidence, said that Mr. Cotton was in his service as surgery dispenser for three and a half years. In April, 1923, Cotton gave him a month's notice, but afterwards desired to come back into his service, and when he would not re-engage him certain anonymous and other letters followed, leading up to the present charge. He emphatically denied that Cotton ever took part in any operation requiring special skill or professional knowledge, or that Cotton had treated or attended for the purpose of treating any patient with his approval. He had employed Cotton to make inquiries as to how patients were going on; he would himself call if Cotton's report made it appear necessary. Cotton took temperatures, but he never allowed him to see a case which he had not first seen himself. Dr. Griffith's case-books were closely scrutinised by the Council, and he was asked many questions relating to the attendance on specific cases. The Council found that the facts alleged against Dr. Griffith had not been proved.

Friday, Nov. 30th.

The Case of Trevor Owen Williams.—T. O. Williams, registered as of 4, Ullet-road, Liverpool, had in 1917, when a captain in the Royal Army Medical Corps, been court-martialled, found guilty of drunkenness whilst on active service overseas, and dismissed from His Majesty's Service; had, in 1922, been reprimanded by a judge for being drunk whilst giving evidence; and had, in 1923, at the Liverpool police-court, been convicted of being drunk and disorderly, and fined. This case was adjourned from the November session, 1922, when Dr. Williams gave to the Council a solemn undertaking to refrain from drink for the rest of his life. Dr. Williams did not appear in answer to the Council's notice, and Mr. Harper, the Council's solicitor, read a letter from the Commissioner of the Salvation Army at Liverpool, in which it was stated that Dr. Williams had placed himself in the hands of the Salvation Army with the intention of overcoming his tendency to drink. The commissioner, writing with experience of many similar cases, asked for a further postponement of this case for a period of six months. The Council, in view of the intervention of the Salvation Army, regarded the case as exceptional and adjourned consideration thereof till the May session, 1924.

The Case of Charles Harold Bennett.—C. H. Bennett, registered as c/o P. Turner, 4, Adam-street, Adelphi, had between 1913 and 1923 been seven times convicted of drunkenness in Liverpool, Uxbridge, and London. Dr. Bennett did not appear in answer to the Council's notice, although the Council's solicitor had repeatedly attempted to induce him to do so. The Council directed that his name be erased from the Medical Register.

Cases Forwarded by the Dental Board.

Two cases were forwarded by the Dental Board with recommendations to the Council that the names of the dental practitioners concerned should be erased from the Dentists Register. *Stuart Christopher Nicoll*, registered as of 28, High-street, Newport, Mon. ("Dentist, 1921"), was convicted of theft at the borough police-court, Newport, in 1923, and sentenced to two months' imprisonment with hard labour. *Thomas William Cook*, registered as of 356, Walworth-road, London, S.E. ("Dentist, 1921"), was convicted in 1923 at the County of London sessions, of receiving property, knowing the same to have been stolen, and sentenced to six months' imprisonment in the second division. The Council directed that the names of these two practitioners be erased from the Dentists Register.

Preliminary Meeting of the Executive Committee.

At the meeting of the Executive Committee on Nov. 26th, before the commencement of the public session, the **President** read a letter from Sir Gilbert Barling stating that he was unable to be present owing to duties as a returning officer at the General Election. Among the items of business were the following:—

Reappointment of Members of the Council.

The official notification of the reappointment of the following members of the Council was read: Dr. Edward Magennis (Apothecaries' Hall of Ireland) for one year from August 1st, 1923; Sir John Moore (Royal College of Physicians of Ireland) for one year from Oct. 18th, 1923; Dr. Denis J. Coffey (National University of Ireland) for three years from July 30th, 1923; Dr. J. B. Leathes (University of Sheffield) for three years from Oct. 27th, 1923.

Restorations to the Medical Register.

The **Registrar** reported the restoration of the names of the undermentioned persons to the Medical Register:—

Edgar Annequin, Henry C. Beasley, Emanuel O. Beckley, Thomas A. P. Benbow, Nadir N. Bharncha, Frederick M. Bishop, Johannes K. J. Chambry, Yun Ying Chen, William J. Corbett, Wilfred A. Dewhirst, Hedley V. Drew, Alexander E. Drynan, Vincent C. Ellis, Reginald C. H. Francis, John J. Glynn, Alfred Golland, Henry C. Goodman, George W. Graham, John H. G. Hunter, Ramchander Kaushosh, Denis J. Keane, James I. Keating, Charles G. King, James Lee, Angus C. Livingston, Joseph J. Long, George W. Matthews, James J. F. Moriarty, Frederick P. Ransom, Lionel M. Rowlette, Elsie M. Royle, Frederick L. Sessions, Andrew F. Sinclair, James W. Sinclair, Emile H. Smith, Arthur F. Stewart, Thos. G. G. Symons, Sydney A. Tucker, Jerry Whitehead, Gomer Williams, John E. Williams, Charles W. Wilson.

British Medical Practitioners in Greece.

Correspondence had passed between the Committee and the Foreign Office and the Ministry of Health with regard to a Bill (enacted in 1922) giving the Greek Government the right to prohibit at any time by Royal Decree the practice of medicine or dentistry in any district in Greece by foreigners, and a decree, formulated under that Bill, prohibiting such practice. The Foreign Office had been informed that the Committee knew of no grounds on which a protest could be entered against the Bill, provided the rights of British practitioners now practising under Greek jurisdiction were safeguarded. The Ministry had been informed that as the authorities in Greece demand that medical practitioners desiring to practise in that country should be naturalised, there appeared to be no prospect of the establishment of reciprocal relations in regard to medical practice between the two countries. It was pointed out that a Greek entitled to practise medicine in Greece might act as physician at a hospital established exclusively for the relief of foreigners in sickness, provided that he engaged in no other medical practice in Great Britain. Further correspondence had passed between the Committee and the Privy Council relating to the case of a practitioner who went to Greece in 1919, attached to the Commission of Reconstruction, and was permitted to practise in the British and American colonies there. He was also medical inspector of the refugee camps under the direction of the Greek Red Cross. The Committee hoped that in these circumstances the authorities in Greece would be able to make such dispensations as would enable this practitioner to continue the work that he was doing.

British Medical Practitioners in Turkey.

The Privy Council had sent for the consideration of the Committee a copy of a despatch regarding the conditions under which foreign doctors may now practise in Turkey. The Lausanne Treaty has allowed the right of the exercise of the profession of medicine in Turkey only to doctors who are Turkish subjects and are furnished with a Turkish diploma. In accordance with these regulations foreign doctors will not be permitted to exercise their profession in Turkey. However, the right of exercise will be respected in the case of doctors who possess permits granted before the war after undergoing examination before the Committee ad hoc.

Foreign doctors practising in Turkey who have Turkish permits or diplomas and have delayed to register were required to present themselves to the Health Direction before Nov. 15th, and show their documents. Foreign doctors who have no Turkish diplomas or permits may now no longer practise their profession, and pharmacists are forbidden to make up the prescriptions of doctors who are not authorised to exercise their profession. Foreign doctors working in hospitals or dispensaries created before the war are also bound to submit to the same conditions. Hospitals and dispensaries opened since the war, but not possessing any recognised official character, were authorised to continue working till Nov. 15th, after which they were to be closed. His Majesty's High Commissioner and his Allied colleagues have addressed an identical note protesting against the despatch, in which they point out that it is in flagrant contradiction to, and clearly constitutes a violation of Article 4 of the Convention d'Etablissement signed at Lausanne between Turkey and the British Empire on July 24th last. It is added that the Turkish sanitary authorities state that all Red Cross institutions are to be closed, and it is possible that the British Seamen's Hospital might also be affected. The Committee resolved to send a reply to the Privy Council on similar lines to that sent in regard to Greece.

British Medical Practitioners in Italy.

An Italian Royal Decree of March 25th, 1923, reads as follows: "Italian subjects and foreigners who have duly obtained a professional diploma in an institute of a foreign State can also be inscribed, when such State has *come to a special agreement* with the Italian Government on the basis of absolute reciprocity of treatment for Italian subjects holding Italian diplomas." In answer to a request for information on this matter received from the Ministry of Health, it had been stated that, as complete reciprocity in regard to medical practice was established with Italy in March, 1901, and confirmed by Italian legislation of date June, 1910, it did not appear that the new regulations affected Great Britain.

OTHER BUSINESS.

Removal of Name from Medical Register at Practitioner's Own Request.—The Executive Committee having considered an application from Dr. Joseph McDonnell, registered as of Roscommon (L.R.C.S., L.R.C.P. Edin. 1864, L.M. 1879), to have his name removed from the Medical Register on the ground of having ceased to practise, the Council, on Tuesday, Nov. 27th, accepted the Committee's recommendation that the name be removed with the knowledge and consent of Dr. McDonnell, and directed that this be done.

Alteration of Personnel of Committees.—On Thursday, Nov. 29th, the Council agreed to a resolution by the Irish Branch Council to the effect that Dr. Kidd should replace Sir Edward Coey Bigger on the Education Committee, and that Sir Edward Coey Bigger should replace Dr. Kidd on the Examination Committee.

Reports of Committees.

The following reports were considered on Friday, Nov. 30th.

Dental Education and Examination Committee.—Sir James Hodsdon (chairman) presented this report to the Council. The report stated, inter alia, that the inspector had been present at three examinations, and one report from a body examined had been received, but that the Committee proposed to postpone the publication of the report until the inspection was completed. Six colonial and foreign applications for registration in the Dentists Register had been received, and it was recommended that four of these be acceded to. With regard to Japanese dentists duly registered in London, in 1918 diplomas of Doctor of Dental Surgery granted by the Nihon Dental College and the Tokyo Dental College were recognised as admitting to the foreign list of the British Register; in the light of a communication received from the Japanese Embassy in London, the Committee recommended that such recognition be extended to the degree of Bachelor of Medicine in the Dental Division of the Tokyo Imperial University, and to the degrees of Bachelor of Dental Surgery of the Osaka, Tokyo, and Nihon professional schools of Dental Surgery.

The report was received and its recommendations adopted by the Council.

Education Committee.—This report was presented by Dr. J. Yule Mackay (chairman). An application had been received from the Pharmaceutical Society for the recognition of their preliminary examination for the purposes of the registration of medical students. It was stated that a considerable number of pharmaceutical chemists took up medical studies at an age long past school age. The Committee resolved that this examination could only be recognised provided it was accepted by one of the English universities in lieu of their entrance or matriculation examination. The Committee had also considered the minimum age at which it was advisable to admit persons of mature years to matriculation under exceptional conditions, and resolved that it was desirable that the age of 21 years should be regarded as the minimum age at which a medical student should be admitted to matriculation under exceptional conditions.

The report was received and its recommendations adopted by the Council.

Pharmacopœia Committee.—This report was presented by Sir Nestor Tirard. The number of copies of the British Pharmacopœia, 1914, sold by the publishers between May 28th and Nov. 26th, 1923, was 1351 copies against 2297 copies sold in the previous year. The total number sold since the date of publication was 45,788. The Committee had considered a communication from the Privy Council, submitting for consideration and observations a draft of an Order in Council under the Dangerous Drugs Act, setting out particulars to be stated on the label of preparations containing poisons: (*a*) In the case of articles to be exported from Great Britain by wholesale dealers or sales by wholesale or retail dealers in the ordinary course of wholesale dealing with the name of the poison, and in the case of a preparation which contains a poison as one of the ingredients thereof, with such particulars as to the proportion which the poison contained in the preparation bears to the other ingredients as may be prescribed by Order in Council; and (*b*) in the case of all other sales in addition to the foregoing particulars with the name and address of the seller of the poison. The Committee agreed to reply to the effect that there did not appear to be anything in the draft to which the Council would take exception, provided that it should be made clear that medicines supplied to a patient by or on the prescription of a duly qualified medical practitioner are not affected by the new Order. The Committee also considered a communication from the Privy Council enclosing a draft proposing certain changes in the Schedule of Poisons appended to the Pharmacy Acts, and agreed to reply that the proposed changes were desirable, but made verbal suggestions for the sake of greater clearness.

Public Health Committee.—This report, presented by Sir John Moore (chairman), dealt with business transacted since the previous meeting of the Council in May and June, 1923. The Committee had been asked by the Director of Medical Services, General Headquarters, Parkgate, Dublin, whether Rule 3 of the Resolutions and Rules for Diplomas in Public Health now in force (which rule provided that a certificate might be given by a sanitary staff officer of the Royal Army Medical Corps having charge of an army corps, district, command, or division recognised for the purpose by the General Medical Council) could be made to apply to the Assistant Director of Medical Services i/c Sanitation, Irish Free State Army, and to the Commandant i/c School of Sanitation, Curragh Camp, so that a number of officers might be able to take their D.P.H. lectures this year. The Committee recommended that certificates under Rule 3 might be given by the two officers in question until Jan. 1st next, when the new Rules come into force. In accordance with a recommendation of the Public Health Committee, adopted by the Council on June 2nd, 1923, a letter had been addressed to the English Conjoint Board on June 7th, 1923, asking for further particulars in regard to exemptions granted to two candidates for the Diploma in Public Health. A reply from the Conjoint Board, dated June 28th, 1923, had cleared up the matter, and the Committee recommended that the answer of the English Conjoint Board be accepted, but they also recommended that in future no exemption to the rules for the Diploma in Public Health be granted except by the General Medical Council.

The report was received, and its recommendations adopted by the Council.

The proceedings of the session closed on the afternoon of Friday, Nov. 30th.

CRIME AND INSANITY

IN THE LIGHT OF THE REPORT OF LORD JUSTICE ATKIN'S COMMITTEE.

THERE is much that is satisfactory in the report [1] (briefly summarised in THE LANCET last week) of the Committee appointed to consider the law, practice, and procedure of criminal trials in which insanity is pleaded. It should reassure the public, for it reaches the conclusion that "to the insane person justice is done." The Committee says it could discover no case in which a miscarriage of justice had taken place in the execution of an offender. Another matter for satisfaction is the fact that the views of the medical profession have been fully stated to, and fully studied by, the Committee, and that they have had some effect upon the findings. On the major issues raised by the inquiry it might roughly be stated that on one point the law is prepared to correct itself; on two points it adopts the medical view; and elsewhere it stands firm. The report is at pains to show how little the legal and the medical view really differ. At any rate it leads to a better understanding if each side makes its position clear to the other. The recommendations of the Committee are printed below, together with a statement of the rules in McNaghten's case, to which reference will presently be made. It is perhaps needless to point out, firstly, that the Committee was not a Royal Commission representative of all shades of opinion, but was a body of experts in criminal law and its administration, a body composed of strong judicial, forensic, and Home Office elements; secondly, that lawyers proceed cautiously in matters of this kind; and thirdly, that no judge is bound by any of the Committee's findings; some of them will require legislation, but of this we are not likely to hear for some months.

Verdict "Guilty but Insane" to be Corrected.

The point upon which the law is prepared to correct itself arises out of the irrational verdict "guilty but insane." The word "guilty" means criminally responsible, yet the verdict means criminally irresponsible. It is thus a contradiction in terms. The explanation is this. Down to 40 years ago the nineteenth century jury could give a verdict of acquittal on the ground of insanity. In 1882 Roderick Maclean fired a loaded pistol at Queen Victoria, was tried for high treason, and, being in the usual way found "not guilty but insane," was ordered to be detained during Her Majesty's pleasure. The Queen, as Mr. Lytton Strachey has recounted, could not understand the verdict. How could Maclean be "not guilty" when she had seen him fire the pistol herself? If that was the law, the law must be altered, and altered it accordingly was. In 1883 Parliament changed the form of verdict; thereafter juries could find a man like Maclean guilty of the act charged, but insane at the time when he did it. This verdict, which gradually became abbreviated to "guilty but insane," the Committee's third recommendation proposes to correct. If Parliament agrees, the future verdict will be that the accused did the act, but is not guilty because he was insane (so as not to be responsible according to law) at the time. It may be added here that both the British Medical Association and the Medico-Psychological Association pressed for a right of appeal against verdicts of this nature. The Committee rejects the idea. It treats such a verdict as a decision in favour of the accused, a verdict which haa been invited on his behalf. Criminal law does not contemplate that a prisoner shall appeal from a decision which is in his favour. If there were such an appeal, the only result would be that he would have to be sentenced or else re-tried on the issue (which would not really be in dispute), whether or not he did the act alleged.

On two points, it has been stated above, the Committee adopts the medical view. There has been a feeling on the medical side that the medical expert in giving evidence in criminal trials is hampered in stating his conclusions. The Committee, without formulating this as one of its recommendations, observes: "We think that a wise discretion would allow all necessary expert evidence as to the general mental condition as a preliminary to evidence directly bearing on the ultimate legal issue raised by the plea." The second point on which the legal view gives way is in respect of acts committed under uncontrollable impulse. The Committee considers that the McNaghten rules (which in all other respects it desires to retain unchanged) are a formula "not logically sufficient" in such cases. It considers it should be made clear that the law does recognise irresponsibility on the ground of insanity where the act was committed under an impulse which the prisoner was, by mental disease, in substance deprived of any power to resist. This view forms the first of its recommendations. How great a concession to medical opinion it represents may be apparent to those who heard the cautious observations of the Lord Chief Justice on this point at THE LANCET Centenary dinner (see p. 1269).

Lessons of the McNaghten Trial.

The rules in McNaghten's case, to which this addition is proposed, otherwise explain themselves. It may be worth while, however, to dwell a little upon the facts of that famous trial. Daniel McNaghten was a man with a good head for business, who, to many people, displayed few signs of abnormality. But he got an impression that he was persecuted by the Tories, and so, after hanging about Whitehall and the Houses of Parliament for several days in 1843, he shot Edward Drummond, private secretary to Sir Robert Peel, in the street opposite Charing Cross, apparently mistaking him for Sir Robert Peel himself. To realise the humaneness of his trial in 1843, it is only necessary to go back a generation earlier to that of Bellingham who, in somewhat similar circumstances, shot the Prime Minister in the lobby of the House of Commons. Bellingham had been a Liverpool merchant in the Russian trade. He had been imprisoned in Russia for debt, got an impression that the British representatives in that country had not been helpful enough, brought his grievance home to England, where he freely advertised it, and finally shot Mr. Perceval, the Prime Minister, on Monday, May 11th, 1811. He was tried at the Old Bailey on the following Friday. Evidence was offered that his father had died insane, and the names of witnesses were mentioned who could testify to the madness of the son. The court would not wait to hear them. Bellingham was convicted and sentenced, and on the following Monday, within a week of his offence, he had been hanged and his body lay exposed upon the dissecting table. His hurried fate aroused no compassion in a public which was indignant at his crime. With such intemperate haste let us contrast the trial of McNaghten in 1843. When his case came on, a fortnight after the murder of Drummond, a month's postponement was at once granted in order that evidence of the unsoundness of his mind might be collected. Eventually, important evidence was produced; he was brilliantly defended by Cockburn; nine medical witnesses were called, who were permitted to give their own conclusions from the facts proved, unrestrained by any idea that they might thereby be usurping the functions of the jury. The prosecution had no rebutting medical evidence; the two medical experts employed by the Crown entirely agreed with those called for the defence; the Chief Justice, obviously impressed by the number and unanimity of the doctors, stopped the case, and the jury returned a formal verdict of "not guilty on the ground of insanity." The ease of McNaghten's escape from the gallows took the country rather aback. The public grew a little restive and frightened. The Law Lords expressed the view that it was a pity that the case was not fully tried. Thereupon the Lord Chancellor took the opinion of the judges, and thus there came into being the famous questions and answers known as the Rules in McNaghten's case (printed below). Subsequently, public feeling became more tranquil. It was seen that the acquittal was not unreasonable, and thus contemporary medical opinion obtained a considerable victory. Medical knowledge, of course, has made much progress since 1843, but these details have been recalled to show how admirably humane and how modern in its spirit was this famous trial of 80 years ago.

Conflict of Medical and Legal Views.

Comment might be made on other aspects of the recent inquiry. The main point on which the lawyers stand fast is their conviction that a man may be insane and yet may be criminally responsible. The medical profession approaches this position from another angle. To medical science a man who is to-day a certified lunatic may for a long while have been in a morbid condition, exhibiting symptoms which the ultimate insanity explains to have been merely successive stages of the same mental disease. In relation to crime the lawyers declare this to be too wide, too uncertain a conception of insanity. They want to be able to make the reservation that in the earlier stages of these symptoms the man may have been "affected by every motive for committing or abstaining from committing a criminal act that would be likely to affect a person of sound mind and in substantially the same degree." The medical view, according to the lawyers, tends to say that any unsoundness of mind means criminal irresponsibility; this "would introduce so much uncertainty into the administration of the criminal law as to create a public danger." The apprehensions of the criminal lawyers are perhaps natural. The Home Office and the Director of Public Prosecutions can hardly be expected to agree with those who assert that crime itself is a symptom of insanity. To alienists the assertion may be a truism; to those responsible for administering the criminal law it is a startling paradox. But though the latter insist that an insane person may be criminally responsible, though high authorities like Sir Herbert Stephen would even be prepared in certain cases to leave a lunatic to be hanged, it must be remembered that in practice they are merciful if in theory they are severe. Every death sentence in England seems automatically to find its way into the Court of Criminal Appeal on the ground of insanity if no other ground is available. And at any rate in the case of McNaghten (as perhaps in that of Ronald True) the administration of the law was in advance of the popular standards of the day. In the face of this fact medical opinion must not be too impatient if the law moves slowly.

The Committee's Recommendations.

The following are the recommendations of the Committee:—

1. It should be recognised that a person charged criminally with an offence is irresponsible for his act when the act is committed under an impulse which the prisoner was by mental disease in substance deprived of any power to resist. It may require legislation to bring this rule into effect.
2. Save as above, the rules in McNaghten's case should be maintained.
3. Where a person is found to be irresponsible on the ground of insanity, the verdict should be that the accused did the act (or made the omission) charged, but is not guilty on the ground that he was insane so as not to be responsible, according to law, at the time. The existing statutory provision in this respect should be amended.
4. Until such amendment, the verdict should always be taken and entered as guilty of the act charged, but insane so as not to be responsible, according to law, for his actions at the time.
5. Accused persons should not be found on arraignment unfit to plead except on the evidence of at least two doctors, save in very clear cases.
6. The present law as to appeal should not be altered—i.e., there should be no appeal on the finding of insanity either on arraignment or after trial and, in the latter case, either as to the act or omission, charged or as to insanity.
7. Provision should be made, under departmental regulations, for examination of an accused person by an expert medical adviser at the request of the prosecution, the defence, or the committing magistrate.
8. Provision for a panel or panels of mental experts is unnecessary.

As to the Criminal Lunatics Act, 1884.

9. It is essential that the statutory power under section 2 (4) should be maintained.
10. The procedure under the sub-section is satisfactory and does not require amendment.
11. The discretion of the Secretary of State should be exericsed as at present.

RULES IN MCNAGHTEN'S CASE (1843).

Rule 1.

Question.—"What is the law respecting alleged crimes committed by persons afflicted with insane delusion in respect of one or more particular subjects or persons: as, for instance, where, at the time of the commission of the alleged crime, the accused knew he was acting contrary to law, but did the act complained of with a view, under the influence of insane delusion, of redressing or revenging some supposed grievance or injury, or of producing some supposed public benefit?"

Answer.—"Assuming that your lordships' inquiries are confined to those persons who labour under such partial delusions only, and are not in other respects insane, we are of opinion that notwithstanding the accused did the act complained of with a view, under the influence of insane delusion, of redressing or avenging some supposed grievance or injury, or of producing some public benefit, he is nevertheless punishable, according to the nature of the crime committed, if he knew at the time of committing such crime that he was acting contrary to law, by which expression we understand your lordships to mean the law of the land."

Rules 2 and 3.

Question 2.—"What are the proper questions to be submitted to the jury where a person alleged to be afflicted with insane delusion respecting one or more particular subjects or persons, is charged with the commission of a crime (murder, for example), and insanity is set up as a defence ? "

Question 3.—" In what terms ought the question to be left to the jury as to the prisoner's state of mind, at the time when the act was committed ? "

Answers 2 and 3.—" As these two questions appear to us to be more conveniently answered together, we submit our opinion to be that the jury ought to be told in all cases that every man is to be presumed to be sane, and to possess a sufficient degree of reason to be responsible for his crimes, until the contrary be proved to their satisfaction ; and that to establish a defence on the ground of insanity it must be clearly proved that, at the time of committing the act, the accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or, if he did know it, that he did not know he was doing what was wrong. The mode of putting the latter part of the question to the jury on these occasions has generally been, whether the accused at the time of doing the act knew the difference between right and wrong ; which mode, though rarely, if ever, leading to any mistake with the jury, is not, as we conceive, so accurate when put generally and in the abstract, as when put with reference to the party's knowledge of right and wrong, in respect to the very act with which he is charged. If the question were to be put as to the knowledge of the accused solely and exclusively with reference to the law of the land, it might tend to confound the jury, by inducing them to believe that an actual knowledge of the law of the land was essential in order to lead to a conviction : whereas, the law is administered upon the principle that every one must be taken conclusively to know it, without proof that he does know it. If the accused was conscious that the act was one that he ought not to do, and if that act was at the same time contrary to the law of the land, he is punishable ; and the usual course, therefore, has been to leave the question to the jury, whether the accused had a sufficient degree of reason to know that he was doing an act that was wrong ; and this course we think is correct, accompanied with such observations and explanations as the circumstances of each particular case may require."

Rule 4.

Question.—" If a person under an insane delusion as to existing facts commits an offence in consequence thereof, is he thereby excused ? "

Answer.—" The answer must, of course, depend on the nature of the delusion ; but making the same assumption as we did before, namely, that he labours under such partial delusion only, and is not in other respects insane, we think he must be considered in the same situation as to responsibility as if the facts with respect to which the delusion exists were real. For example, if, under the influence of his delusion he supposes another man to be in the act of attempting to take away his life, and he kills that man, as he supposes, in self-defence, he would be exempt from punishment. If his delusion was that the deceased had inflicted a serious injury to his character and fortune, and he killed him in revenge for such supposed injury, he would be liable to punishment."

Rule 5.

Question.—" Can a medical man, conversant with the disease of insanity, who never saw the prisoner previously to the trial, but who was present during the whole trial, and the examination of the witnesses, be asked his opinion as to the state of the prisoner's mind at the time of the commission of the alleged crime, or his opinion whether the prisoner was conscious at the time of doing the act that he was acting contrary to law, or whether he was labouring under any, and what, delusion at the time ? "

Answer.—" We think the medical man, under the circumstances supposed, cannot, in strictness, be asked his opinion in the terms above stated, because each of those questions involves the determination of the truth of the facts deposed to, which it is for the jury to decide, and the questions are not questions upon a mere matter of science, in which case such evidence is admissible. But where the facts are admitted, or not disputed, and the question becomes substantially one of science only, it may be convenient to allow the question to be put in that general form, though the same cannot be insisted on as a matter of right."

OLD CHURCH HOSPITAL, ROMFORD.—An operating theatre constructed on up-to-date principles was opened at this hospital on Nov. 29th. It has been built at a cost of £1970, and is situated at the back of the nurses' home. The medical superintendent, Dr. W. S. O'Loughlin, said that a new theatre had long been required. Mr. A. H. Todd paid a tribute to the nursing staff, and Dr. J. G. McDougall and Dr. J. A. Fraser also spoke.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

FOLLOWING are some of the principal health statistics of three cities and two county boroughs for 1922 :—

Town.	Estimated population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality		Maternal mort. in childbirth.
							Legit.	Illegit.	
Bristol	383,900	19·9	13·3	1·3	1·2	3·0	72	116	2·9
Newcastle ..	281,600	24·8	14·2	1·5	1·1	4·2	91	118	4·0
Salford	240,700	22·1	14·6	1·6	1·1	4·4	109	141	3·5
Cardiff	203,700	21·6	13·2	1·5	1·0	3·7	79	169	6·1
Sunderland ..	162,900	28·6	15·7	1·3	1·3	5·2	99	287	3·2

Bristol.

Dr. D. S. Davies comments on the deficiency of the isolation hospital accommodation. The extension scheme approved in 1914 has never yet been carried out. There are only 240 beds and during times of pressure the guardians and general hospitals have given assistance. The excessive prevalence of encephalitis lethargica, resulting in an aggregate of 108 cases between Jan. 1st, 1919, and Sept. 30th, 1921, did not continue during 1922, during which year there were 8 cases and 4 deaths. The report of Dr. Allan C. Parsons to the Ministry of Health (1922), quoted by Dr. Davies, does not suggest that the behaviour of this disease in Bristol was exceptional. The three home nurses, appointed in February, 1919, under the provisions of the Maternity and Child Welfare Act, 1918, have been found useful in checking both measles and diphtheria epidemics. Dr. Davies thinks that their efforts in carrying nursing aid and instruction to the mothers in the diphtheria epidemic, which reached its height in December, 1921, in the well-populated Bedminster district, were most valuable.

The report includes an interesting dissertation on tuberculosis, with a chart dealing with the ten years 1913–22, which indicates the prevalence in Bristol of the " young adult " type of pulmonary tuberculosis. The council have approved of arrangements for the provision of 60 beds for surgical tuberculosis in children at Lord Mayor Treloar's Hospital and of 100 beds at Frenchay, but both these schemes have been delayed by the Ministry on the plea of economy.

Repair work in housing has been encouraged by somewhat lower prices. " Gross overcrowding is far too rife," says the chief housing inspector, " and it is useless to take any action." " The absence of houses is a very serious handicap for young people," he continues, " if they have to start their married life in a bed-sitting room in an already overcrowded house. The bottom drawer is not required to-day. The common occurrence of births taking place in the presence of other members of a family has ceased to shock, and, on the grounds of morality and decency, prompt steps should be taken to overcome all obstacles." Comments are made on the unworkable nature of Section 28 of the Housing Act of 1919, which was intended to facilitate the renovation of houses. Dr. Davies sums up the situation by saying : " No real solution of the housing difficulty will be found until circumstances permit the unrestricted re-establishment of private endeavour, so that supply may follow demand."

Newcastle-upon-Tyne.

Dr. Harold Kerr thinks unemployment benefit and the National Health Insurance Act have proved very important public health measures during the industrial depression. Unemployment figures for the city improved as industry recovered from the effects of the coal strike of 1921, but after May, 1922, the conditions became worse, and at the end of the year there were 19,500 men and 1200 women idle. Atmospheric pollution showed an improvement on 1921, but this may have been due to trade depression. Dr. Kerr comments on the increase in deaths from diseases of the heart and blood-vessels, and thinks this may be partly due to the saving of life at earlier ages. Cancer, on the other hand, has shown no definite tendency to increase in Newcastle during the last 15 years. Diseases of the digestive system were less fatal in 1922, as they were in 1918, and Dr. Kerr suggests that shortage of money in 1922 and the limited choice of dietary in 1918 had similarly beneficial effects in restricting the population to plain and wholesome food. The influenza epidemic struck the city with great suddenness about Jan. 4th, was extremely prevalent during January, declined gradually, and disappeared about the end of February. It proved chiefly fatal to babies and adults, older children and adolescents being comparatively lightly affected.

Newcastle has escaped small-pox since 1910. In 1922 30 per cent. of the babies received exemption certificates, and in surrounding districts only about one in five of the babies born is vaccinated. A small outbreak of seven cases of enteric fever was associated with the milk from a dairy, probably originating with a farm outside the city, but the cause could not be definitely traced. Dr. Kerr thinks that owing to the efforts of the health visitors measles is now treated as a serious ailment and is consequently much less fatal than formerly. He also thinks that opportunities of infection with infantile diarrhœa are much lessened, as compared with ten years ago, "by the general use among non-breast-fed children of dried milk in place of the much more readily contaminated fresh form of the commodity," and that as the result of the teaching of the centres "the present-day Newcastle mother knows much more about baby-care than did her mother."

Two outbreaks of food poisoning occurred. One was associated with soup made from a ham-bone and left standing in a warm place in a kitchen in a poor neighbourhood; three persons were ill, one fatally. Two other consumers of the soup remained quite well but harboured the infecting organism, the *Bacillus enteritidis* of Gaertner, for about a week. The other outbreak was apparently caused by canned beef; 36 persons in 7 families were known to have been affected. The symptoms were acute but passed off in two days and there were no deaths. Later, information from the Ministry was received of three similar outbreaks in various parts of the country, apparently due to canned beef packed by the same firm. The infecting organism was not discovered in any of the outbreaks. The average stay in hospital of scarlet fever patients suffering from nose and ear discharges has been reduced by engaging a specialist, Dr. Neil Maclay, for the treatment of these complications. Promising results are also claimed from the prophylactic use of a detoxicated vaccine prepared from cultures of organisms from cases of scarlet fever developing ear and nose discharge.

A special effort has been made to follow up patients who discontinue treatment at the V.D. clinic, and the proportion of patients who cease attendance prematurely has been reduced from 30 per cent. in 1921 to 23 per cent. in 1922. Hostel accommodation is needed for infected girls and unmarried mothers. Four policewomen have done good service in patrol duty and in detective work in connexion with charges of abortion and treatment by unqualified persons. Dr. Kerr has no doubt of the great value of the maternity and child welfare scheme, and shows that the saving of life in the first year is coincident with a saving in the next four years. He evidently much regrets the cutting down of the staff by the dismissal of eight health visitors in 1921 and a reduction in the medical service, resulting in overcrowding at the centres, &c. New centres are now being opened and the medical sessions increased.

The report of the tuberculosis officer (Dr. W. H. Dickinson) shows that in spite of a steady reduction during recent years, Newcastle-upon-Tyne shares with its neighbours—Gateshead, South Shields, and Tynemouth—the unenviable distinction of having, in recent years, the heaviest death-rates from tuberculosis of all the county boroughs in England. Dr. Kerr suggests overcrowding as the chief cause, backed up in the case of Newcastle by loss of sunshine owing to the pall of smoke. The principal trades and occupations, he points out, are of a healthy nature. It is difficult to get hold of pulmonary tuberculosis at a hopeful stage, and Newcastle is in the anomalous position of having beds to spare at Barrasford Sanatorium and not nearly sufficient accommodation for advanced cases at the City Hospital. Successful results are being obtained at the various institutions from artificially-induced pneumothorax. Two notable lacks are an open-air school for pre-tuberculous children and accommodation for surgical tuberculosis.

Of 171 samples of milk examined 12, or 7 per cent., were found to contain tubercle bacilli. Owing to pressure of other work the 489 cows stalled in the city did not undergo regular veterinary examination. Slaughtering is carried out on 102 separate premises. A public abattoir, combined with a cattle market and meat market and with provision for the allied offensive trades, is needed, and Dr. Kerr says there is now general agreement that it should be on the outskirts of the city. The raising of the embargo on the importation of Canadian cattle has been accompanied by such restrictions that the Newcastle Corporation have not undertaken the necessary expenditure on wharfage for cattle ships. At the end of the year two farms were producing "Certified" and six "Grade A (tuberculin-tested)." An endeavour is being made to lessen the number of small general shops selling milk. In 1918 there were 668; now there are 266. The difficulty in getting renovation and repairs of houses is slightly decreasing; 523 new homes were provided in 1922 as compared with 305 in 1921, but very many more are still necessary to meet immediate needs. Of the new houses, 442 were built by the corporation on the Walker estate and 22 on the Pendower estate. The housing committee have set an excellent example by providing only one coal fire in each new house, the remainder being for gas. "Overcrowding is the rule and sub-letting is rife. There is no means of controlling this last as yet, and one constantly comes across the most heartless cases of profiteering at the expense of unfortunate tenants of so-called furnished lodgings."

Salford.

Dr. H. Osborne, in presenting his first report, mentions that the final exhortation of his predecessor, Dr. C. H. Tattersall, who resigned after 25 years' service, was as to the urgent need for a maternity home. The new sanatorium at Marple was opened in December. The question of the prevention of respiratory diseases is an urgent one and demands careful attention, and Dr. Osborne has no doubt that the gross atmospheric pollution has an important bearing on their incidence. During 1922, 2728 smoke observations were taken: 121 stokers were cautioned by the inspector; 39 firms were reported to and dealt with by the health committee; and 114 cautionary notices were issued to firms. Two firms were summoned for smoke nuisances and each case was adjourned sine die by the stipendiary magistrate.

Ten of the 197 samples of milk examined for tubercle bacilli gave positive results. The public analyst, Mr. G. D. Elsdon, reports on dirt in milk, and comes to the conclusion that 1 part of sediment per 100,000 parts of milk would be a fair standard to set up and that milk containing 2 or more parts per 100,000 should be classified as distinctly unsatisfactory. The subject is one of peculiar difficulty, he points out, because it is quite easy for the retailer to remove the dirt immediately before sale by decantation or filtration, and thus delude the purchaser into thinking he is buying a clean pure article. He thinks that a standard is badly needed for ordinary milk, and hopes that the "graded" milks, which can be sold at enhanced prices to those willing and able to pay, will not monopolise attention, seeing that ordinary milk will always constitute the bulk of the milk sold in the country. Proceedings were taken for the improper labelling of margarine and fines inflicted. Three of the margarine samples were advertised as blends or mixtures of the finest margarine with best butter, and contained respectively 5, 8, and 10 per cent. of butter fat. As such mixtures are not allowed to contain more than 10 per cent. of butter fat, it is obvious that a purchaser, who does not know the law, may easily be prejudiced by such an advertisement. Mr. Elsdon reports that a large proportion of the rice now sold is not polished or "faced" with talc. Some attention has been given to the amount of tin in tinned goods, the standard adopted being an excess of 2 gr. per lb., in accordance with a L.G.B. report of 1918. A sample of melon and orange jam was found to contain 6 gr. of tin per lb. Mr. Elsdon states that, although it is quite possible to prepare tinned goods containing less than 1 gr. of metallic tin per lb., this figure is frequently largely exceeded, especially in the case of old samples. A great improvement has taken place since samples of prescriptions issued under the Insurance Act were taken for analysis.[1] Thus from 1914 to 1920 the number of adulterated samples was 20 per cent., while in 1921 and 1922 the percentages of adulteration were only 3·9 and 5·4 respectively.

Dr. Osborne's report concludes with a description of the very complete child welfare scheme. There are nine centres and two clinics. Children from the centres requiring treatment or more than weekly supervision are passed on to the clinics and return to the centres when improved. A whole-time masseuse is employed at the clinics and centres with good results. Sessions are held at the clinics for expectant and nursing mothers, who require medical advice for themselves. Thus, skilled attention is available for the child from the time of its conception to the time at which it is passed on to the care of the school medical officer, and when this transference takes place its medical record passes with it, the school clinics and child welfare clinics being housed in the same buildings.

Cardiff.

Dr. Ralph M. F. Picken tells us that the extension of the city in November, 1922, besides adding a population of over 20,000 has introduced problems of a rural nature. For instance, the city dairy-farms have increased from 4 to 33 in number. A comparison of the Census figures of 1911 and 1921 shows that the excess of families over structurally separate houses has increased by 4149 since 1911. There is much multiple tenancy and in the middle of 1921 the excess of families over houses was 10,569. Using various estimates, Dr. Picken thinks that the number of houses which ought to be provided between 1921 and 1931 should be not less than 6000 and nearer 10,000. The number of houses erected during 1922 was only 71, of which 48 are classed as working-class houses. Slums, in the commonly accepted sense of the term, do not exist and therefore Cardiff is not able to put up a case for sharing in the annual Government grant of £200,000 for clearing away unhealthy areas. During the heat wave at the end of May and beginning of June the nuisance caused in Canton district by the variety of mosquito known as the common gnat led to an inquiry as to the types of mosquito existing in the neighbourhood. Dr. Simpson, of the Welsh National Museum, reported that the great majority of larvæ submitted to him were of the culex or gnat variety, but that two were of the anopheles type. The number of cases of malaria notified in 1922 was 15, all of which were infected abroad. Quite apart from the malaria risk, culex bites are a source of great discomfort, and steps have been taken, with the advice of Mr. John F. Marshall, hon. director, Hayling Island Mosquito Control, to endeavour to prevent mosquitoes breeding in the district.

Sunderland.

Dr. Henry Renney submits a table showing the result of the bacteriological examination of the water. The Sunderland water is derived from deep wells in the Magnesian Limestone. The Newcastle water is a pure upland surface water collected from large catchment areas near the Cheviots and in lower Northumberland. The Sunderland water is not filtered, while Dr. Kerr tells us that in the case of Newcastle there has been no increase in the area of the filter-beds or the storage capacity of the reservoirs during late years coincidently with the increased consumption of water. It is therefore interesting to compare the results of the bacteriological examinations during 1922 side by side:—

Class.	Water examinations, 1922.	Sunderland.	Newcastle.
I.	Colon bacilli not found in 100 c.cm.	67	2
II.	,, ,, found in 100 c.cm.	87	71
III.	,, ,, ,, ,, 10 c.cm.	32	100
IV.	,, ,, ,, ,, 1 c.cm.	2	16
	Total samples examined..	188	189

Both these waters are believed to be of great purity and, in view of Sir Alexander Houston's recent investigations, it is possible that seagull-droppings are the chief source of the colon bacilli in each instance.

Dr. Eustace Thorp, reporting on child welfare work, thinks bronchitis and rickets are exceptionally prevalent, and that "scarcely any baby in Sunderland attains the age of 1 year without suffering from one or more attacks (of bronchitis)." Treatment for otitis media is badly needed. Miss Barber, the chief health visitor, reports that four of the eight centres are decidedly overcrowded. "The grants of dried milk to necessitous cases have been a great help to many poor infants and nursing mothers." Midwives attended 76 per cent. of the births. The guaranteed salary (£150) of the midwife appointed for the East End has been repaid in fees to the Corporation. The Midwives Medical Aid Fund still operates. Each midwife pays 1*s*. 6*d*. of her 25*s*. fee to this fund, and out of the fund the midwife's fee is paid if a doctor has to be called in, the doctor's fee being paid by the patient. A charge upon the rates is thus avoided.

SCHOOL MEDICAL SERVICE.

Northamptonshire.

THE average number of scholars on the roll here was 28,248, and of these 10,479 were medically examined during the past year, 7885 of these being in the code group. Of the latter 955 were referred for actual treatment; 290 are recorded as being below standard nutrition. There were no cases of "bad" nutrition; 7·38 per cent. of the children were of "excellent" nutrition. Altogether there was a total of 96·32 per cent. normal and excellent nutrition, against 94·78 per cent. in 1921. Defective vision requiring treatment was found in 295 cases. Myopia occurred in the age-group up to 10 years, boys 11 per cent., girls 14 per cent., and in 11 years and over, boys 31 per cent., girls 39 per cent. It is pointed out that these figures show no disproportionate increased incidence in girls as is usually stated. Fifty-three boys and 102 girls were found to be myopic and 258 boys and 343 girls hypermetropic. Dr. C. E. Paget reports that a persistent fight is being made against uncleanly conditions, with the result that one school in a large urban area is declared to be "nit free"—a great achievement. The circulation of this fact with the name of the school ought to help considerably in getting a high standard throughout the county.

Corrigendum.—Dr. A. G. Jenner writes to point out that he is both medical officer of health for Stockport and also medical officer to the Education Committee. The two school medical officers are Dr. W. H. Rowell and Dr. Taylor-Haworth. We are glad to make this clear.

THE LANCET CENTENARY DINNER

THURSDAY, NOVEMBER 29th, 1923.

THE dinner given to THE LANCET in celebration of the Centenary of the paper was held at the Hotel Victoria, Northumberland-avenue, on Thursday, Nov. 29th, Sir DONALD MACALISTER, President of the General Medical Council, in the chair.

SPONSORS FOR THE DINNER.

Among those present as sponsors for the dinner or their guests were the following:—

S.E. Cmte. de Saint-Aulaire, French Ambassador; the Rt. Hon. Lord Hewart, Lord Chief Justice of England; Sir Squire and Lady Sprigge; Sir Ernest and Lady Hodder-Williams; the Rt. Hon. Viscount Burnham, C.H.; the Rt. Hon. Sir Louis Newton, Lord Mayor of London; the Rt. Hon. Lord Dawson of Penn, G.C.V.O., K.C.M.G., M.D.; the Rt. Hon. Lord Riddell; Sir Humphry Rolleston, K.C.B., M.D., President, Royal College of Physicians of London; Sir John Bland-Sutton, F.R.C.S., President, Royal College of Surgeons of England; Vice-Admiral J. Chambers, C.B., C.M.G., Medical Director-General, Navy; Lieut.-General Sir William Leishman, K.C.M.G., Director-General, A.M.S.; Major-General John B. Smith, C.B., President, India Office, Medical Board; Air-Commodore David Munro, C.I.E., Director of Medical Services, Royal Air Force; Lady Barrett, M.D., M.S., President, Medical Women's Federation; Sir George Newman, K.C.B., M.D., Chief Medical Officer, Ministry of Health and Board of Education; Sir Berkeley Moynihan, Bt., K.C.M.G., Professor of Clinical Surgery, Leeds; Miss Louisa Aldrich-Blake, M.S., M.D., Dean, London School of Medicine for Women; Sir Charles Sherrington, G.B.E., President, Royal Society; Sir William E. Berry, Bt.; Sir William Hale-White, K.B.E., M.D., President, Royal Society of Medicine; Dr. Herbert Spencer, President, Medical Society of London; Sir George Buchanan, C.B.; Sir Richard Douglas Powell, Bt., K.C.V.O., M.D.; Sir John Tweedy, F.R.C.S.; Sir George Makins, G.C.M.G.; Sir James Hodsdon, K.B.E.; Sir Edward Coey Bigger, Medical Commissioner, Local Government Board, Ireland; Mr. H. J. Waring, M.S., Vice-Chancellor, University of London; Sir Anthony Bowlby, K.C.B., K.C.M.G., K.C.V.O.; Sir Archibald Garrod, K.C.M.G., M.D., F.R.S., Regius Professor of Medicine, Oxford; Sir Walter Fletcher, K.B.E., F.R.S., Secretary, Medical Research Council; Sir Stanley Leathes, K.C.B., First Civil Service Commissioner; Prof. T. K. Monro, Regius Professor of Medicine, Glasgow; Mr. C. P. Childe, F.R.C.S., President, British Medical Association; Prof. R. A. Bolam, O.B.E., Chairman, Council, British Medical Association; Sir Dawson Williams, M.D., D.Sc., C.B.E.; Major Ian Hay Beith, Chairman, Society of Authors; Mr. H. A. Gwynne; Mr. H. T. Cadbury; Dr. A. D. Brenchley, Senior Warden, Society of Apothecaries; Sir John MacAlister, Secretary, Royal Society of Medicine; Mr. Sheriff R. Christopher Sennett, and Mr. Sheriff T. Middleton Dron.

The vice-chairmen of the different tables were Mr. Willmott Evans, Mr. James Berry, Dr. Marguerite Kettle, Mr. H. D. Gillies and Dr. J. H. W. Laing (hon. secretaries), Mr. Percy Hodder-Williams, Dr. E. C. Morland, Dr. R. A. Young, Dr. John Freeman, Dr. W. Essex Wynter, and Mr. R. E. Sare (general manager of THE LANCET).

LIST OF THOSE PRESENT.*

Mr. J. Johnston Abraham, C.B.E., D.S.O., Dr. L. B. Aldrich-Blake, Dr. C. McArthur Allan, Mr. Donald Armour, C.M.G., Sir Robert Armstrong-Jones, C.B.E., Dr. Dorothy W. Atkinson.

Dr. Alfred Baldock, Sir Charles Ballance, K.C.M.G., C.B., Dr. H. W. Barber, Sir Gilbert L. Barling, Bt., Mr. A. E. Baron, Sir James Barr, C.B.E., Lady Florence E. Barrett, Mr. Leslie Barringer, Mr. W. H. Battle, Mr. A. Beverley Baxter, Mr. H. Wansey Bayly, M.C., Mr. A. R. Beaumont, Major Ian Hay Beith, C.B.E., Dr. H. Windsor Bell, Dr. T. Izod Bennett, Dr. Frances M. D. Berry, Mr. James Berry, Sir William E. Berry, Bt., Sir Edward Coey Bigger, Dr. J. Wilson Black, Sir George Blacker, Mme. Blaise-Juppé, Sir John Bland-Sutton, Dr. J. Blomfield, O.B.E., Mr. R. B. Blumenfeld, Prof. R. A. Bolam, O.B.E., Dr. W. A. Bond, Sir Anthony Bowlby, Sir John Rose Bradford, K.C.M.G., C.B., F.R.S., Major J. H. Brannigan, Dr. A. D. Brenchley, Lady Briscoe, Sir Charlton Briscoe, Bt., *British Medical Journal*, Sir John F. H. Broadbent, Bt., Mr. Lancelot Bromley, Mr. Morris W. Browdy, Sir Bruce Bruce-Porter, K.B.E., C.M.G., Mr. C. W. G. Bryan, M.C., Dr. George F. Buchan, Sir George S. Buchanan, Prof. P. Bull (Christiania), Rt. Hon. Viscount Burnham, Mr. Cecil Burnham, Dr. Lancelot S. T. Burrell, Dr. J. E. B. Burroughs, Dr. Dudley W. Buxton, Dr. E. Farquhar Buzzard, Colonel W. Byam, O.B.E.

Mr. Henry T. Cadbury, Dr. F. Foord Caiger, Dr. J. Walter Carr, C.B.E., Mr. Robert Carswell, Dr. Aldo Castellani, C.M.G., Dr. Joseph Cates, Dr. George C. Cathcart, Vice-Admiral Joseph Chambers, Mr. R. W. Chapman, Mr. Francis Charlesworth, Sir G. Lenthal Cheatle, K.C.B., C.V.O., Mr. C. P. Childe, Dr. H. P. Cholmeley, Mr. C. C. Choyce, C.M.G., C.B.E., Miss H. Ethelberta Claremont, Dr. Leslie H. Clarke, Mr. Ernest Clarke, Dr. F. G. Clemow, C.M.G., Dr. C. A. Clouting, Dr. H. A. Clowes, Dr. W. Ponsonby Cockle, Dr. Robert H. Cole, Dr. William Collier, Dr. J. T. Conner, Mr. Frank Cook, Mr. Edred M. Corner, Lieut.-Colonel Trevor Cory, M.D., Dr. Sidney Coupland, Dr. George Cowie, Dr. Alfred Cox, O.B.E., Sir Maurice Craig, C.B.E., Sir Anderson Critchett, Bt., K.C.V.O., Dr. W. M. Crofton, Mr. J. CrowleSmith, Prof. Winifred Cullis, Dr. Millais Culpin.

Daily Telegraph, Sir P. Daniels, K.B.E., Dr. Arthur T. Davies, Dr. Edward D. D. Davis, Rt. Hon. Lord Dawson, Dr. J. F. Gordon Dill, O.B.E., Dr. E. C. Dodds, Mr. Sheriff T. M. Dron, Sir James Dundas-Grant, K.B.E., Mr. Percy Dunn, Dr. William Dunn.

Dr. Sybil Eastwood, Mr. W. McAdam Eccles, Mr. F. W. Edridge-Green, C.B.E., Dr. Henry A. Ellis, Mr. Guy S. Elliston, Mr. Willmott Evans, *Evening Standard*, Mr. John Everidge, Dr. J. Eyre.

Dr. John S. Fairbairn, Dr. John Fawcett, Mr. J. H. Fisher, Mr. Percy Flemming, Dr. Emily Flemming, Dr. H. Morley Fletcher, Sir Walter Morley Fletcher, Mr. Alex. G. R. Foulerton, Dr. Owen Fowler, Mr. Claude Frankau, C.B.E., D.S.O., Mr. Philip Franklin, Dr. John Freeman, Dr. Herbert French, C.B.E.

Mr. F. H. Gamble, Mr. Eric W. Gandy, Sir Archibald E. Garrod, Dr. J. G. Garson, Dr. Arthur E. Giles,

THE LOYAL TOASTS.

Proposed by the Chairman (President of the General Council of Medical Education and Registration).

After the Grace, said by the Rev. A. Whitaker Oxford, M.D., Sir DONALD MACALISTER gave the toast of "The King." He said: His Majesty has been graciously pleased to accept a diploma form of the honorary Fellowship of the Royal College of Surgeons of England, but with equal graciousness he has been pleased to refrain from presenting, or causing to be presented, that diploma before the General Medical Council for registration. He has thus most considerately relieved that body and its President from an embarrassing situation, for which act of grace they are humbly and respectfully thankful; but His Majesty has given abundant and most welcome proofs of his deep personal interest in the physical health and well-being of his subjects, and of his personal sympathy with the ministrations of the medical profession directed to that end. For that reason I ask you, not as loyal subjects only, but as loyal members of that profession of which His Majesty is himself an honorary member, to join me pledging enthusiastically His Majesty's health and happiness, and long prosperous reign over us. In the old words, I give you, "The King, God Bless Him."

This toast having been drunk with expressions of enthusiasm, the CHAIRMAN gave the toast of "The Queen, the Queen Mother, the Prince of Wales, and Other Members of the Royal Family," remarking: What can I say more or better than that they in a thousand ways are ever showing forth the gracious spirit that animates them in the furtherance of those works of benevolence associated with healing and the relief of human suffering which lie within the special province of our profession. In no previous reign and in no other country have the Queen and the other members of the Royal House held a higher place in the affections, professional as well as domestic, of all who are called, whether as doctors or nurses, whether in the war-like services or in civil life, to safeguard and promote the public health. For their devotion

THE LANCET CENTENARY DINNER.

THE LIBRARY
OF THE
UNIVERSITY OF ILLINOIS

to that end we give them our loyal and continuing gratitude. In testimony of our affection—our loyal and admiring affection—I ask you to drink with me to the Queen, Queen Alexandra, the Prince of Wales and the other members of the Royal Family.

In calling upon the Rt. Hon. Lord Hewart, Lord Chief Justice of England, to propose the toast of the profession of medicine, the CHAIRMAN said: There is an ancient Latin tag, *Salus populi suprema lex*, but as the compulsory study of Latin is no longer enforced for medical qualifications, at least in London, I will translate for the benefit of the ladies: *salus populi*, the medical profession; *suprema lex*, the Lord Chief Justice of England.

"THE PROFESSION OF MEDICINE."

Toast Proposed by the Lord Chief Justice of England.

Lord HEWART said: It is an honour and a pleasure to propose the toast of medicine. I am forcibly reminded of a rather ancient story about Lord Palmerston at a Ministerial whitebait dinner at Greenwich. It was said of him that he looked at the dish of appetising whitebait that lay on the table before him, then took a glance at the interesting countenances of his colleagues in the Cabinet, and said: "Do let us follow the excellent example of these wise little fishes; let us drink a great deal and say nothing." This always seems to me to be an excellent maxim for a festival occasion. I never felt the truth of it more than I do to-night. Perhaps this is not solely, although mainly, a festive occasion. You, Mr. Chairman, in that brilliant, but, I regret to say, inaccurate translation of the phrase which you have just used coupled medicine and law. While there is no doubt a close association between medicine and law, both the legal profession and the medical profession receive unstinted and universal gratitude and appreciation. These two professions have very few critics. It was never said, so far as I know, of the medical profession that it had ever devoured widows' houses. With the single exception of the law, there is no profession more devoted to the art of healing than the medical profession. With the single exception of the law, there is no greater, no wiser, no more humane profession than that of medicine. I will go one step further and add that next to the law there is no more ancient profession than the medical profession. At a gathering about a year ago there were those who traced the history of the medical profession back to Herodotus, and reference was made to the ancient art as practised among the Egyptians. There were those who carried the history back to Homer. But there was one—the Prince of Wales—who carried the history back to the Garden of Eden, and he said that already in those comparatively early times Eve had learned the truth that "an apple a day keeps the doctors away."

May I, however, say one serious word upon a matter which has recently come before the public and is likely in a different form at no very distant time to come before the public again. It is often said that upon the difficult question of insanity, as it is understood by the law, there is a serious conflict between the view of the lawyer and the view of the physician. I express no opinion on that matter, but there has recently been set up a committee of lawyers who have inquired into the matter, and, as I understand, the report of that committee contains a recommendation for something which, if adopted, will undoubtedly mean a wide expansion of the criminal law. At present if a person is to be held not responsible for a crime upon the ground of insanity, he must fulfil one of two tests. He must satisfy one of two conditions, either that by reason of infirmity of mind due to disease of the mind he must not know that what he is doing is wrong, or he must not know what he is doing at all. That is an ancient maxim of English law. Medical science is, I understand, not satisfied with those two alternatives. It suggests at least a third alternative—that a man may know what he is doing and may know that what he is doing is wrong, and yet by reason of disease of mind may be uncontrollably compelled to commit that act. It is this condition which, I understand, is now recommended by the committee upon the advice of eminent specialists. I express no opinion, but one thing is clear. If that is indeed to be the law—and *salus populi suprema lex*—I do not suggest that we shall launch out upon a sea which has no shore, but, at any rate, we shall launch upon a sea of which the shores are far more widely separated than are the shores which, as lawyers, we have hitherto known.

Before I sit down, I will just say one word upon the more immediate occasion of this gathering. This is, as you all know, the hundredth anniversary of the existence of that great medical publication, THE LANCET, and in the presence of those who are immediately responsible for it I will refrain from expressing the compliments which, if they were absent, we should all be disposed to express. But one may say that it is fortunate indeed for the medical profession and for the public of this country that it so long had, and now has, a periodical of that distinction, that knowledge, that wisdom, and, may I add, that public spirit. I have the honour to couple with the toast two names which are household words to the medical profession throughout the country, the name of Sir Humphry Rolleston, President of the Royal College of Physicians of London, and Sir John Bland-Sutton, President of the Royal College of Surgeons of England.

Response by the President of the Royal College of Physicians of London.

Sir HUMPHRY ROLLESTON said: To respond to such a far-reaching toast as the profession of medicine on such an occasion and before such a representative and highly critical assemblage is a proud honour, but not without serious responsibilities. On this unique anniversary our thoughts are naturally directed to the century of medicine that THE LANCET has chronicled so faithfully, and indeed at times painted in somewhat dramatic colours, thus exerting an influence at times stimulating, at others counselling moderation, and always wholesome. During this eventful period—by far the most momentous in medical history—the picture has completely changed, the science of medicine has been revolutionised; the art has made giant strides. So much so, that whatever the condition of the body politic, and at the moment "tranquillity" is hardly the word, we may feel tempted to adopt the attitude of Dr. Pangloss to the effect that the present is the best of all possible eras of medicine, and certainly there is some excuse for laying such flattering unction to our souls.

The last hundred years has seen the rise and results of laboratory research in medicine. So far back as a hundred years ago the modern laboratory idea originated, for in 1824 Purkinje's physiological laboratory in Breslau and in 1825 Liebig's chemical laboratory in Giessen were established; for a time progress in these directions was slow, but the leading position of British physiology and neurology must be regarded as the outcome of this method of investigation. The middle third of the nineteenth century was pre-eminently that of structural pathology, while the remaining part of the century saw the rise of ætiology after the founding of bacteriology by Pasteur and Koch; Lister's practical application of this new science to surgery was followed by Almroth Wright and the dictum that "the physician of the future will be an immunisator"—an ideal not yet finally accomplished. With the inspiration of ætiology, preventive medicine, especially in tropical diseases, has, under the guidance of Manson, Gorgas, Ross, and others, led to enormous saving of human life, and untold economic benefit to mankind. The present century is the era of research into functional disorder, of biochemistry or the further stage of physiological chemistry, of chemotherapy, and of comparative medicine and pathology.

A remarkable feature of quite recent years, dating mainly from the war and after, is the increasing share taken by the Government in the prevention and control of disease. The Medical Research Council, appointed in June, 1913, like the panel system, the offspring of the National Insurance Act (1911), has all the enterprise, enthusiasm, and originality of youth. Its success under the direction of Sir Walter Fletcher is an answer to the fears that Government control must strangle initiative in the coils of red tape. The Ministry of Health has enormously expanded the province under the control of the old Local Government Board, and what it will do in the future it is possible only to guess by reading between the lines of its chief medical officer's reports. What the future may bring forth in the way of State service and State-run hospitals remains to be seen, and though this consummation does not appear to be devoutly wished for, it should be considered with an open mind.

In the past British science and medicine has been much indebted to independent individual effort, but with the increasing specialisation of knowledge combined effort or team-work is becoming more general both in research and in clinical practice. In the case of research this does not mean that the influence of the individual genius will be dwarfed, but rather that side-issues and details will be worked out in due proportion. Research has largely taken the form of the application of methods in the allied sciences, such as chemistry and physics, to clinical medicine, and by these means and by the great advance in preventive medicine, knowledge and control have been gained to a greater extent over the external forces of Nature acting on the body than over the methods of reaction of the human body to external influences ; the early stages of disease still remain a problem for extensive investigation, as Sir James Mackenzie has so often insisted.

But what of the future ? While congratulating ourselves that we are not as the early Victorians, ought we not to reflect that we are only just looking out on the promised land of health and are far from a position to rest complacently on our oars ? We should realise that what Wakley's days are to the present, so will our position be to the editor and readers of THE LANCET in 2023.

Response by the President of the Royal College of Surgeons of England.

SIR JOHN BLAND-SUTTON said : In every form of religion among people, savage or civilised, men have believed that gods, from time to time, assume the forms of animals and, in fleshly garb, render service of a supernatural kind to mankind. Physiologists have proved that the condition of human beings, rich and poor, is not under the influence of gods or demons, but our gross bodies contain small bodies, called ductless glands, which make, and secretly discharge, occult fluids into the blood-stream to be distributed throughout the body for good or for evil !

It is on the action and interaction of the gods in our glandular pantheon that life and health depend ; also our fatness or thinness ; morality or moroseness ; wit or wantonness. They can make us famous or notorious ; giants or dwarfs. Should one of the gods be too active, or idle, the balance is upset, and clever physicians study the signs and symptoms, and frame a diagnosis, which to the patient, often seems like an act of divination. He then endeavours to restore the balance by administering an extract of the corresponding gland of a chimpanzee, armadillo, calf, goat or an A double S.

To-day, the treatment of diabetes engrosses men's minds. This involves the consideration of sugar. Interesting stuff is sugar whether we regard it in relation to the world of commerce, or the realm of science. Enormous fortunes have been made, and lost, in the production of sugar. It has entailed as much misery on human beings in the West Indies as ivory to the natives on the West Coast of Africa ! The over-production of human sugar is a source of much misery to thousands upon thousands of patients. It is a matter of interest to the physiologist, a source of profit to the physician, and dismay to the surgeon. Unsuspected sugar in the urine is a serious obstacle to an operation. It is like an uncharted rock to a mariner. The discovery of the relation of the pancreas to diabetes came as a surprise. The islets of Langerhans, at first mere histological curiosities, are of more importance to mankind than the comet reported to be visible in the constellation of the Ram.

Recently I was dining in the company of physicians, some of them eminent ; they plumed themselves on the fact that doctors, existing on human sickness and frailty, do their best to destroy the provocative agents of disease which enable medical men and women to make some sort of a living. This encomium does not apply to insulin, because patients who can afford to buy it must have the stuff administered by a doctor of skill. I can say in all sincerity, the discovery of insulin has seriously increased the cost of sugar to the producer. On careful inquiry I find that the treatment of a rich diabetic by a fashionable physician with this newly discovered preparation amounts to £700 or even £1000 yearly. This would, of course, include the cost of the insulin and the regular quantitative estimation of the blood-sugar by a laboratory authority. Let us fervently hope that some brilliant biochemist will discover a synthetic drug or a coal-tar product which will make diabetics independent of insulin. If such a substance were produced and be easily purchasable, like aspirin, some enterprising druggist would make an enormous fortune. Such a successful man might turn philanthropist, devote a portion of his wealth to rebuild the Royal College of Physicians, and also provide pensions for physicians who had been impoverished by the absence of diabetics from their consulting-rooms.

If Thomas Wakley could revisit the scenes of his strugglings and strivings, the contemplation of such changes would surely make him gape with astonishment !

"THE LANCET."

Toast Proposed by the Professor of Clinical Surgery at the University of Leeds.

SIR BERKELEY MOYNIHAN said : The pleasurable duty has been laid upon me of proposing the toast, "Prosperity to THE LANCET," a toast which will be most cordially and sympathetically welcomed by everyone here to-night. There is no man but wishes well to his friends, and THE LANCET, throughout the lifetime of us all, has been the good friend of our profession, and of every member of it, and of every interest the profession upholds. It has inspired, guided, and embodied the opinion of our leaders. It has helped to interpret for us our duty to the high cause we serve, to the public, to our professional brethren, and to ourselves. And all this has been done without fuss or clamour, with fair and gentle statement on every issue, strong where strength was needed, but at all times persuasive rather than compelling, and certainly in every way free from taint of self-interest or the least suspicion of other unworthy motive. What, then, can we do but pray for continued "Prosperity to THE LANCET" ?

The methods of THE LANCET were not always so gentle. A hundred years ago the profession was the victim of many gross abuses, the chief of which were imposed upon it by men within its own ranks. The Apothecaries Act had been passed only eight years before THE LANCET first appeared. There had been neither time nor opportunity nor any inclination to organise the profession. Indeed, organisation of our profession for united action in any cause however good, on any occasion however opportune, under any auspices however favourable, seems even now almost unattainable. In those days the profession suffered many things, both vexatious and intolerable. The shameless practice of nepotism, the harsh and unjust ordinances of governing bodies, the despotic methods of teachers and examiners, rankled in the minds of men. Yet there was no redress; the submission, the subjection even, of students and practitioners alike was complete. And then THE LANCET came, and all was changed.

It was an age of unrest when men had ceased to reverence authority. The revolt of America, the French Revolution, the juggling with thrones and with peoples that was the sport of Napoleon, had all unsettled the minds of men and made them impatient of sceptred control. Rebellion was in fashion. THE LANCET, conceived in a spirit of reform, was nurtured in this atmosphere of revolt, and Wakley lost no opportunity for the display of vivid and unfaltering courage, when he set out to attack privilege founded on injustice and used only for selfish ends. His first and avowed aim was the dissemination of accurate medical knowledge, but in such a time so narrow a restriction was hardly possible. It was not to be imagined as the sole purpose of such a man as Wakley. Of him, his character, his ideals, his methods, we have learnt all that we know from the life written years ago by THE LANCET'S present Editor. As we look back we can see that Wakley's principles were in almost every instance right. His modes of procedure were at times crudely conceived and they were often conducted with the most savage rancour. He was fighting selfish interests deeply intrenched, interests completely disdainful and neglectful of the rights of others, and it is possible that no other methods than his would so surely have effected his purpose. His onslaught was terrific, in virulence, in volume, and in nagging persistence. He bestowed just enough praise upon individuals, and upon the conduct and results of operations to make his criticism of failures even more devastating. His evident affection and high regard for Sir Astley Cooper, "the Prince of Surgeons" in his day, did not save Sir Astley's relatives from the bitterest taunts. When Sir Astley assailed the practice of extreme salivation by mercury in the treatment of venereal disease, the surgeons to the Borough Hospitals were held to be arraigned. In his next lecture, Sir Astley Cooper asked: "Who are the men, gentlemen, against whom it has been supposed that these observations were directed? Are they men whom I could possibly feel disposed to injure? Mr. Travers was my apprentice, Mr. Green is my godson, Mr. Tyrrel is my nephew, Mr. Key is my nephew, Mr. Morgan was my apprentice." His very defence, you observe, was an admission of his guilt in respect of the nepotism of which Wakley so constantly accused him.

A favourite butt for Wakley's ridicule and invective was Sir William Blizard, an old gentleman for whom I have acquired a certain affection. For as I sit in the Council Chamber of the Royal College of Surgeons his portrait confronts me, and I seem in the lapse of years to have learnt to know and respect him. Wakley, describing in a few brisk phrases the surgeons of his day, tells us that Abernethy "consigns an examinant's eyes to perdition," and that Blizard avows a "horror of hats." In his category of surgeons, Wakley says, "there are some who shed lustre on their profession, some who cant, others who re-cant, and one who desires members of the College to take off their hats." Wakley inquires whether the proceedings at the Royal College of Surgeons can be opened in any other manner than by Sir W. Blizard desiring the members "to take off their hats," and he suggests that Blizard might take a lesson from an anecdote of the ancestor of the Prince de Levi, which shows that there is no rational or religious foundation for such a horror of hats. The Prince de Levi, who piqued himself on the antiquity of his family, showed to a lady, who visited him at Paris, his pedigree from the Flood; and when it came to the birth of Christ, De Levi's ancestor was represented as standing by the Virgin and Child, with his hat off, and there was a scroll from the Virgin's mouth saying, "Mon cousin, mettez le chapeau." "Pray, cousin, be covered." A few weeks later in an account of visits to the various hospitals, interesting cases are related from the Middlesex and Westminster Hospitals, but of the London Hospital this is recorded: "The only case of interest at this hospital, for a long time, has been that of Sir William Blizard; the congenital irritability of this patient of late has materially diminished. This happy and beneficial effect is attributed to the judicious application of 'The Lancet.'" Sir William was finally the subject of the first "medical portrait" which appeared in THE LANCET in 1833, when the victim was just 90 years of age and within a year or two of his death. The portrait was ruthless and vindictive, but its subject, far advanced in years, practising and teaching effete methods, and still tenacious of high office, did certainly group within his own person many of the offences to which Wakley was so bitterly opposed.

To Wakley's achievements we owe both admiration and gratitude. His robust and fearless independence, his faith in great causes, his loathing of injustice, his frank disdain for professional eminence based upon the favour of others and not upon industry that has been sternly tested and intellectual supremacy that has been fairly and openly won, all appeal to us. His pungent wit, his blistering satire, his merciless invective, all attract us, for though they are harshly, they were never once, I think, unfairly used. Men such as he are called into being in all countries, but especially perhaps in our own, when the human spirit is roused to violent upheaval and embittered antagonism by the exercise of power bereft of true authority, of strength devoid of right, of control dictated only by caprice.

But destruction, malicious or not, was by no means the only effect of Wakley's labour. It is, perhaps, a fair claim that no man has contributed more than Wakley to the constructive work which has distinguished the growth of our profession in the last century. It was at his instigation that Warburton's Committee (upon which served a kinsman of my own) was formed. The Medical Act of 1858, the charter of our profession, was certainly due more to him than to any other man. He formed an intellectual alliance with other countries, chiefly with France. He published the lectures of Dupuytren, Magendie, and Andral, and Cooper's lectures published by him were translated for the French journals. And as the years passed by he drew to himself, in steadily increasing numbers and sometimes into close association, those members of our profession who sat, or were soon to sit, in high places, and who in no small degree directed the professional destinies of their fellows. He sacrificed no single principle, but remained to the end obdurate and unwavering in his defence of what he believed to be right and in his relentless assault upon what he knew to be wrong. It was the conversion of others to *his* views, the recognition that his causes were just, that finally established him in the opinion of all men as the greatest of our reformers, and as a true benefactor to our profession. The monuments that are raised to the memory of our benefactors are of every order. Some are carved in stone and some are cast in bronze. The greatest memorial to Hunter is the incomparable museum that bears his name, in our College. Mankind will foreever bear living witness to the genius of Lister. Many of you whom I see here to-night have your own memorial in the grateful hearts whose heavy load of suffering and of sorrow your strong hands have lifted. Few monuments are so noble, few will be so enduring as the journal which perpetuates the memory and the labours of Wakley.

From his day to ours THE LANCET has progressively grown in influence and in authority. In its pages the story of the advance of medicine is steadily unfolded. With its help greater medicine, medicine in its full relation to the public welfare and the public safety has been inaugurated and its growth encouraged. The world is a little weary of journals, especially of those which seek an ever larger circulation, and ever greater power while a little unmindful of the high responsibility which rests upon them. Is not the first duty of journalism to educate, to draw the individual out of himself, to direct and enlarge his outlook, to create and foster a sense of his corporate responsibilities and to bring him, no matter how remote his home, into intellectual and emotional contact with his fellows; in a word, to be for him the messenger of light and truth? For such a task vigour there must always be, and humour will not come amiss, but honesty in search, sanity in exposition, with truth as the distant goal, are attributes of an ideal journalism. All these THE LANCET has long shown, and shows now more plainly than ever under its present Editor.

Of Sir Squire Sprigge I will not venture to express any personal opinion, but I may be allowed to say that in his hands the future prosperity of THE LANCET is assured. We all realise his unsurpassed knowledge of the wide and various problems covered in these days by the single word "Medicine." He has a keen and proper sense of the part which our profession ought now to play in its relations with the public. Resolute of purpose, he has integrity of thought, sobriety of judgment, and an admirable lucidity of expression. He enjoys in fullest measure the high regard, the trust, and the affectionate admiration of his professional brethren.

I ask you therefore—

In honour of the memory of its Founder,

In gratitude for all its labours towards the welfare of our profession,

In confident hope for its future,

to drink the toast, "Prosperity to THE LANCET."

Proposed from another aspect by the Proprietor of the "Daily Telegraph."

Viscount BURNHAM said: I am very proud on behalf of the newspaper press of this country to be allowed to join in proposing and toasting the famous journal the centenary of which we are here to celebrate. We are all here equally proud of that high tradition founded on patriotic motives and technical efficiency which has made THE LANCET what it is—the gospel and literally the good tidings of national health. We exult, too, in the spirit of independence it has shown, which has never brooked control, in the fullness of its knowledge, which is only bounded by the scientific attainments of its contributors, and by its love of truth, which is founded on the maxim that "Truth is the basis of all excellence." We of the daily and weekly press are too fond of imagining that we are the whole of the newspaper press, and we are apt to forget that part of it which is devoted to professional and technical interests, and of which some would say that the half undoubtedly is better than the whole.

I would say this, too, that whilst our circulation is in the main national, the circulation of such of the scientific press as is represented by THE LANCET is world-wide, and wherever you go in the British-speaking countries, or even outside them, you find that half of the British press upheld and recognised as setting a standard of veracity and initiative for all alike. Of that kind of paper THE LANCET is undoubtedly a fine example. Especially does that count when the world generally is getting rather tired of words, no longer believing that salvation cometh out of rhetoric, and is more inclined to turn to the things that really matter, whether they are clothed in beauty of phrase or not. I can say, too, that no paper has ever reflected in all its essentials the characteristics of its founder better or longer than THE LANCET. Its methods may now be more tender, but its principles are the same, and in its virility and sincerity it is the express image of Thomas Wakley.

The world knows, or anyhow cares to know, little of its greatest men, but if you have any sense of the reality of things you must recognise that Thomas Wakley was one of the makers of modern England. He declared against shams and make-believes, against quacks and all those who tried to deceive the public. He had no reverence for ancient abuses, nor did he believe in the interests that were vested in ignorance and brutality. Why he should have been inspired to do all he did because he was unfortunately mistaken for the hangman and despoiled of his goods by members of a political conspiracy, I do not know, but he made up his mind that his life was to be a crusade and a crusade he made it. He must have passed almost as much of his time in the law courts as he did in Bolt Court in the old offices of THE LANCET, and ten actions were brought against him in the early years of his strenuous journalism. But you whom he chastised have been singularly forgiving, because you honour his memory whenever it is mentioned. Undoubtedly when he first rose to fame the medical profession was not much further from those days when Bacon said: "It hath been more profound than laboured; and yet more laboured than advanced; rather in circle than in progression." How did he leave it? At the end of his stormy and strenuous life you know that, after being thrown out of the building by Bow-street runners, he opened the door of the College of Surgeons and freed it from the bonds of a close corporation. He made you as a profession recognise, for the first time, the rule of public responsibility, and he dispelled the professional obscurantism which had been the practice of medicine in the past.

He cleansed, so far as was possible in those times, the coroner's court, and insisted that the coroner ought to have the technical qualification which fitted him for the discharge of his duties. He forced the attention of the public to the question of the adulteration of food, and, through THE LANCET'S analytical commissions and by a Committee of the House of Commons prepared the way for the Scholefield Act, which for the first time protected the health of the community as consumers. All this he did, and I am glad to know that THE LANCET has always clung to the spirit of his work, and is to-day what its Founder would have hoped that it might always be. I can only hope that it may long be able to take its share in the inestimable work of reducing the sum of human misery, and adding to the great and essential quantity and quality of the public health. It has now passed into the possession of a firm of publishers whom we all know and honour, and I am certain that in the hands of Sir Ernest Hodder-Williams it will suffer nothing, either in its technical excellence or in honourable conduct.

Response by the Editor of "The Lancet."

Sir SQUIRE SPRIGGE said: It is usual at old school dinners, old college dinners, and similar functions to obtain a speech from a senior, who speedily drops into reminiscent vein and usually allows that when he was a lad he was a devil of a fellow. In such a connexion a bishop or a judge, by confessing to us that he once fought a river-side character on the boat-race day, achieves a success in words which may not have attended his fists. Now, of course, THE LANCET is a senior. In its youth it has been described to you as a devil of a fellow, an allusion made both by Lord Burnham and Sir Berkeley Moynihan, who gave me the exact opening, almost an invitation, to relate how in our youth we fought the bargees of nepotism and corruption. But I decline the invitation to be reminiscent, though with nothing but satisfaction at the memories evoked. The past outrageous energies can never be repeated by us. You see the distinguished men who have done us the high honour of being with us this evening. No doubt they in their youth resisted discipline and embarked on adventure. Perhaps without such individuality they would never have gone so far, and it was a gallant sight, I am sure, to see them in their youth; but a brawling minister is unthinkable, and a bishop with a torn apron or a judge with his wig on the green would not only be a pathetic sight but their great future utility would be prejudiced by the episode; and it is to our career of extended utility that I wish to come. The violence of past days is gone, but the desire for the right and zeal to achieve it remain as forcible as they were 100 years ago, and we shall press towards the mark of our ideals with unabated energy, even though without the concomitants of egal struggles or personal bickerings.

We have had before us over the century two ideals —the maintenance of the status of medicine and the diffusion of medical knowledge—and to their accomplishment our best endeavours will be used. The Centenary Dinner of THE LANCET is a milestone on the road to progress, and not our obituary tombstone. And as for myself, while I thank you from the bottom of my heart for your kind reception of my association with this toast, I must say that I am only the robin sitting on the milestone twittering to call attention to the particular stage. We did not erect the stone; you gentlemen and your predecessors did that, and it is through your continued support and unvarying coöperation that we hope to mark the route of progress at future stages. We depend upon our friends, THE LANCET is, as it must be, a friend-made paper. relying on the good offices of its supporters who read each others' wisdom and clarify or correct each others' views. I also am a friend-made man. And I have called on the services of friends to a shameless extent through school, college, and professional days. I was at the best of schools, and the son of my headmaster and the medical officer of Uppingham School are here to-night. I was at the best of colleges, and my most distinguished contemporary, the President of the Royal Society, who also is here, has remained my friend since those days. I was at the best of hospitals, and its ornament, the President of the Royal College of Physicians, you have listened to. Through school, college, and hospital associations I have exacted levies from friends, and, as time went on, enlarging environment gave me enlarging opportunities for such exactions. So that I know that it is to others that I owe what you have accorded to me. Further, any measure of success which has been obtained has been in return for labours of love. It is they who have to discharge a dull routine and face distasteful duties whose devotion is really admirable. I have enjoyed myself. Medicine may be only one section of the world's activities, but it is an ever-developing and all-permeating one. It has been my delightful duty to record the phases and ramifications of medicine as they are produced and as they are justified by the workers themselves.

Response by the Chairman of "The Lancet."

Sir ERNEST HODDER-WILLIAMS said: I am indeed a very grateful and a very proud man to-night—very grateful to you, Lord Burnham, who have always been so good to mine and to me, for the very kind things you have said about our connexion with this great paper THE LANCET, grateful to all of you my lords, ladies, and gentlemen for the way you have received the toast. I am very proud to stand to-night in this place of a great tradition. Perhaps, under the circumstances, you will allow one personal reminiscence. In the days of my early manhood—and my father, whom I am delighted to see here this evening, will bear me out when I say that at that time one reached early manhood very early—I had the ambition to enter the medical profession, but the Fates, no doubt in kindness to my future patients—the Lord Chief Justice would, I am sure, advise me to add the magic legal phrase "if any"—decided entirely otherwise. They did not, however, altogether forget, and after many years they presented to me a grand old surgical instrument—THE LANCET—fashioned out of a material with which I had become somewhat acquainted. And when I use the personal pronoun may I say at once that I refer not only to myself but to all my splendid associates and very specially to the best of brothers. As proprietors of this paper we made a vow and we took a pledge—we have tried to keep them. The vow was and the pledge was that we would, as far as in us lay, do nothing which might leave the slightest stain of dishonour on a most highly honoured name. That pledge we have tried to keep, we shall try to keep in the future, even though it should mean —as in the case of Wakley—having our houses burned down and gutted, even if it means that we have to fight half a dozen libel actions in as many years, even if it means (which heaven forbid!) that one of us has to enter Parliament. Well, we must vote and see. We indeed were fortunate that when a change of proprietorship took place there was no change in the editorial leadership. From the moment when we first met Sir Squire Sprigge until now there has not been one single matter of policy—and matters of policy are vital to those who are responsible financially, and some people would say morally, for the contents of the paper—there has not, I repeat, been one single matter of policy upon which we have not been in spontaneous and complete accord, and I take this opportunity of thanking Sir Squire Sprigge and the whole of his staff for the way in which they have worked with us. It is a pleasure, and it is going to be a pleasure for many years to come, to work with them and for them. In these latter years laymen, business men and business women, have worked increasingly side by side with professional men and professional women in many fields of service of peace and of war, in none, I think, with greater honour to themselves and to their cause than in the field of healing. It is because of this that we business men who control the destiny of this grand old paper, THE LANCET, feel so deeply our responsibility, our privilege and our opportunity. If we can be of any service to you in scattering far and wide the fine grain garnered from your knowledge and your experience—if we can be of service to you in breaking up the stony ground, in rooting up and utterly destroying those tares of ignorance which still so often choke the finest growth—then perhaps we may have some small share in the joy of your reaping.

"THE GUESTS."

Toast Proposed by the Chairman of the Medical Consultative Council, Ministry of Health.

Lord DAWSON said: After so much brilliant oratory I should ill requite the kindness of our guests in gracing our feast if I submitted them to a recital even of their virtues. If we are right in saying that a man may be judged by his friends, surely this assemblage of varied callings and distinguished talents gives vivid and delightful expression to the appreciation in which THE LANCET is held. And in showing this generous measure of goodwill to THE LANCET you are showing goodwill to medicine, for in a very intimate sense we regard THE LANCET as belonging to ourselves. And I would suggest that professions have need of each others' understanding, and this is more and more true of medicine, for when in former days its scope was limited to the cure of disease in individuals it was possible for it to hold itself in almost monastic detachment from social progress. But in these days when the health of the community is within its orbit and is likely in the future to claim a dominant part of its attention, contact with other callings will be more close and its thoughts and conclusions will be a necessary part of sound statesmanship. And this deeper and steadier statesmanship of the professions will extend a beneficent influence to international relationships in that it will be untouched by those surface disturbances which rise and fall with the changing winds of political exigencies.

The presence of His Excellency the French Ambassador has delighted and honoured us, and brings to mind the admiration and affection which we hold towards our French colleagues. Our sympathy for them is too bright and pervading to be dimmed by any passing clouds of political difficulty. For us the genius of his people creates much for which civilisation stands, and in the field of medicine that genius is ever and abundantly manifest. We have enjoyed the presence of the Lord Chief Justice. It is with us as with all. The disciples of the law not only entertain thought, but can adequately place it, and the Lord Chief Justice has by the magic of the mind and to our enjoyment woven generous thoughts into the beauties of speech. The territories of medicine and law have increasing contact. We deal more with Nature's fashionings of man and they with man's fashionings of himself. Our friends of the Press, who, as always, are so generous in their support to-night, are feeling at the present time some of the difficulties which are apt to beset us. In the nation's present plight we notice in some quarters a conflict of advice, which recalls to my mind " How you doctors always differ," and elsewhere a certain doubt as to the prognosis which leads to what we doctors recognise as " expectant treatment "—a handling of the case which can be modified as circumstances dictate. Even in those Sunday papers which give guidance and entertainment to millions of readers, I find expectant treatment is the order of the day.

Our guests are so varied in their gifts that I could not with any approach to brevity appreciate them adequately. But may I make reference to Major John Hay Beith, known to us all as Ian Hay, who alike with sword and pen has rendered great national service. There is another guest to whom one and all will extend a special welcome, the great-grandson of the Founder of The Lancet—T. L. Wakley, now at Oxford. The love of public service and fearless striving which has descended on him will serve him well, as he stands on the threshold of one of the most interesting periods of English history. We all wish him God-speed. The Lord Mayor links us with the history and administration of this ancient City, which, if so minded, could celebrate not one hundred but 800 years of existence. Moreover, he brings to us to-night not only the good feeling of the City of London, but the lustre of personal distinction earned in the field of civic administration. Sir Dawson Williams, who with the Lord Mayor will respond to this toast, has found in journalism the greatness of medicine and in medicine the greatness of journalism, and to our great advantage upholds the best in both.

This toast gives expression to our joy at the presence of our guests and of our friendship towards them. I give you the toast of " The Guests."

Response by the Lord Mayor of London.

Sir Louis Newton, said: On behalf of the guests I thank you for the delightful evening we have spent, and for the interesting and fascinating account we have had of the career of The Lancet during the hundred years of its existence. I am here to-night to show the great respect felt by the City of London for the eminent medical journal published within its walls. I am also here as President of the Hospital Sunday Fund to bear grateful testimony to the great share the Wakley family and The Lancet had in starting this Fund 51 years ago. Its success has been so great that nearly £3,000,000 have been raised on behalf of the hospitals of London. The Lord Chief Justice, in his interesting speech, showed you to his own satisfaction the close connexion between medicine and the law. Had I the time I might prove to you beyond question the close connexion—a very feeling connexion—between the City of London and medicine. I congratulate you on the fact that you are celebrating the Centenary of a publication of which you can be justly proud, and on my own behalf and that of the City of London, as well as on behalf of many bodies of sincere admirers, I give expression to the hope that The Lancet may live for many centuries to come.

Response by the Editor of the "British Medical Journal."

Sir Dawson Williams said: You, Sir Donald, enjoy a very high reputation with your profession, but I feel that on this occasion you are endangering your reputation for discretion and judgment. I appeal to you whether it has not been altogether superfluous to call on me at this late hour of the evening and after the Lord Mayor has so well expressed the thanks of the guests. I can only excuse you on the ground that I should be allowed the opportunity of speaking in the name of what I suppose is the smallest specialty in the medical profession—the specialty of medical journalism which I have followed for so long—and of offering to The Lancet our congratulations on attaining its hundredth year. Very few journals live for a century. To do so requires great powers of adaptation. Times change and journals change with them. The Lancet has had a succession of able editors, some of whom I have known, while in the hands of the present editor, my friend Sir Squire Sprigge, the vigour of the journal has not in any way diminished. A medical journal in these days, when medicine has become so complicated and the interests of members of the profession are so varied, could not exist unless it had the support of the profession. That sounds like a truism, but I am not thinking of subscription lists, but of the kindly support that comes to us in the many complicated questions with which we have to deal. Specialists in every department place their experience at our disposal. Various motives impel them to do so, the chief, I think, being a real love for their particular subject. They are moved also by the desire to help a brother, and perhaps by loyalty to a particular journal. The conduct of a general medical journal does not get more smooth. It has to some extent to correspond with the complexity of the science with which it deals, while another difficulty is the inordinate length at which so many authors want to write. It is one of the difficulties which beset all kinds of scientific societies. Even the pure mathematician produces in place of a column of text formulæ so long that they must be printed the wrong way of the page. A phenomenon of the time is the multiplication of special journals. It is an admirable movement and one which the general medical press must thoroughly applaud. The men who conduct these journals do so at great sacrifice. But the special medical journal is a sort of large scale ordnance map which a man gets when he is going to buy an estate and has to consider where the different buildings lie, while the general medical journal is the inch-to-the-mile survey giving a general idea of the lie of the country. I cordially associate myself with what has been said about The Lancet and the good wishes that all of us have for its future. It has achieved success because it has known how to meet the needs of the medical profession, and I do not at all doubt that it will continue to do so.

"THE CHAIRMAN."

Toast Proposed by the President of the Royal Society.

Sir Charles Sherrington said that this memorable occasion had derived no little of its success from the genial chairmanship of Sir Donald MacAlister. Late as was the hour, the gathering must not separate without heartily pledging his health.

The Centenary of a Medical Mission.—Sunday, Dec. 9th, will be celebrated as the centenary of the foundation of the Jerusalem Mission of the Church Mission to the Jews. As the work opened in December, 1823, and developed a dispensary side, under Dr. Dalton, an Irish practitioner, within a few months, the event also marks the centenary of modern medical missionary work. This became organised on a permanent basis by the starting in 1844 of a small hospital for the relief of sick Jews by Dr. E. Macgowan, an Exeter doctor, who had joined the mission. This was the forerunner of the fine hospital, the foundation-stone of which was laid in 1895 by Lord Northbrook, which stands to-day as a tribute to the 28 years' work of Dr. Percy d'Erf Wheeler, who went out from St. Thomas's Hospital to Jerusalem in 1886, and is still working for the society in the East End of London. Dr. Wheeler was succeeded for a time by Dr. E. Masterman, now of Camberwell Infirmary. The hospital is now in charge of Dr. H. J. Orr Ewing and Dr. K. W. Kingdon. Miss E. M. Barber is the matron, and is assisted by a staff of 15 British and foreign Christian, Jewish, and Moslem nurses. In-patients number about 1500 annually, and out-patients 6000.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh : Centenary of the Royal (Dick) Veterinary College.

A SERIES of meetings and social functions took place in Edinburgh last week to celebrate the hundredth anniversary of the Royal (Dick) Veterinary College, founded by William Dick in 1823. On Nov. 27th an "At Home" was held in the College by the Principal, Dr. O. Charnock Bradley, at which Sir John MacFadyean, in the name of Emeritus Prof. Duncan McEachran, F.R.C.V.S., of Quebec, Canada, presented to the College a portrait of its founder. In the evening an address was delivered in the University by Prof. Theobald Smith, Director, Department of Animal Pathology of the Rockefeller Institute for Medical Research, Princeton, New Jersey, on Comparative Pathology: Its Biological and Economic Significance. The chair was taken by Sir Alfred Ewing, who referred to Prof. Smith's work in showing Koch to be in error in contending that the bovine tubercle bacillus was not pathogenic to man. Speaking of the relation of animal to human pathology, Prof. Smith pointed out that with the exception of a few diseases, such as rabies, glanders, anthrax, and tuberculosis, most animal diseases did not affect man, but indirectly the relation of the two was important to the welfare of man generally. Thus the study of parasites in animals, such as ascaris in rats and pigs, had pointed the way to treatment of the similar condition in man. Even more generally, comparative pathology was likely to be of service, for the underlying cell processes were the same in all animals, and the study of lower animals in which the factors were less complicated was bound to be of value.

Some Aspects of the Tuberculosis Problem.

At a meeting of the Medico-Chirurgical Society of Edinburgh, held in conjunction with the Tuberculosis Society of Scotland in the Royal College of Physicians on Nov. 29th, Prof. Theobald Smith delivered an address on Some Aspects of the Tuberculosis Problem from the Experimental and Comparative Standpoint. Sir Robert Philip was in the chair. In introducing Prof. Smith, Sir Robert Philip described him as a philosophic pathologist. Prof. Smith's address consisted of gleanings of some 40 years' experience of the problem. He said that the methods of attacking the tuberculosis problem might be grouped under three heads: (1) Preventive, (2) immunisatory, and (3) hæmotherapeutic. With regard to the latter, it was not extravagant to hope that something analogous to quinine in malaria or the arsenical salts in syphilis might be discovered. These might possibly be man's anticipation of methods to be adopted by nature. He went on to give a brief historical sketch of the various problems which had arisen in connexion with tuberculosis since the discovery of the bacillus by Koch in 1882. First came the great attack on the disease from the public health standpoint; then the dramatic introduction of tuberculin in 1890 with its enthusiastic and sanguine reception followed later by disappointment; then arose the discussion as to the path of entry of the bacillus. In 1901 came Koch's dogmatic assertion that the bovine tubercle bacillus did not cause disease in man, and its ultimate refutation. In this connexion Prof. Smith referred to a paper of his own, published three years earlier, pointing out the differences between the two forms. There followed the dispute concerning infection in infancy and childhood, and after that the still disputed question of super-infection. He went on to discuss the contribution of comparative pathology to the solution of these various problems. From this point of view the subject might be approached in one of two ways: by (1) experiments, (2) numerous and thorough autopsies. Experiments were unsatisfactory owing to the modification of the virus by culture. He had had the opportunity to perform 500 autopsies on cows. These presented a series of all stages of the disease. In the majority of these the thoracic lymph glands only were affected. From the distribution of the glands it was possible to say by which part of the respiratory tract the bacillus had entered. In the majority this was the posterior lobe of the lung, corresponding to the lower lobe in human subjects. The frequency of apical infection in man was very possibly due to suppression of the disease in the lower lobes and the greater susceptibility of the upper. Primary disease in cattle was lymphatic, as in children, but the diseases of cattle corresponded to those of childhood and adolescence, as cattle for the most part were killed young. When infection was proved in more than one system, the lesions were all found to be at the same stage, a finding which suggested immunity to fresh infection. The results of the so-called bovo-vaccination experiments showed that in the vaccinated animals the lung lesions were of a broncho-pneumonic character and comparatively mild, whilst those of the controls were miliary and rapidly fatal. This suggested the protective value of small tubercle injections. Public health measures had probably not actually shut the door, as it were, but had reduced the draught. Vaccination, which is nature's method, could not after all be expected to do more than nature, which eliminated the weak. From this point of view there were three groups—namely, those of high resistance for whom vaccination was unnecessary; those of low resistance upon whom it was useless; and those between the two for whom it probably did good. As a biologist he was not hopeful of elimination of the disease, but as a medical man he exhorted all workers to optimism.

The Treatment of Diabetes.

At a meeting of the Partick and District Medical Society on Nov. 22nd Dr. John Gracie delivered his presidential address on Diabetes and Insulin. In the treatment of diabetes, Dr. Gracie said, the essential point was to maintain the blood-sugar well below the threshold value, so that the islet cells of the pancreas might be rested and thus given a chance to regain their full functional activity. The only way to ensure this was by the routine examination of the blood-sugar, since the method of keeping a trace of sugar in the urine not only meant that the islet cells were not being rested, but also might even fail to reveal a hypoglycæmia of transient type. The method adopted by Dr. Gracie was to give all the carbohydrates in the estimated diet in two meals. The dose of insulin was given one hour before each meal, and a blood-sugar estimation performed three hours after the meal. Much stress was laid upon the necessity of combining dietetic with insulin treatment, a necessity not always appreciated by patients whose information was gleaned from the lay press. A basal diet ought always to be calculated, and should be upon a basis of 25 cal. per kg. of body-weight per day. This must include 1 g. protein per kg. of body-weight, while the remainder of the diet was made up of carbohydrate and fat; the former calculated by starving the patient until his urine was sugar-free, and then cautiously adding measured amounts of carbohydrates each day until sugar again appeared in the urine. The type of case suitable for insulin was the one in which a basal diet could not be reached without its aid. Dosage could be estimated upon the basis that one unit of insulin metabolised 2½ g. carbohydrates, although the initial dose should never be sufficient to eliminate sugar from the urine entirely, lest the lack of glycogen in the liver led to hypoglycæmia. He had found that the best diet was one in which the fat only slightly exceeded the protein, his most satisfactory continued diet having been one of carbohydrate 68, protein 114, and fat 127, combined with 30 units of insulin daily—a diet 800 calories over the basal requirements of the case. Additional points of interest were the facts that each change of diet led to an increase in the urinary sugar—even when the carbohydrate in the diet was reduced—the quantity of insulin being kept constant; and that when a constant diet was maintained the quantity of sugar in the urine always decreased.

On Nov. 23rd Dr. George A. Allan delivered to the Ayrshire Division of the British Medical Association an address entitled Diabetes Mellitus and its Treatment by Insulin. In considering the actual indications for the use of insulin, Dr. Allan held that the more severe the case the more necessary was the treatment and the safer its administration. In coma the results might be brilliant. From the point of view of the general practitioner, who had not the time to devote to blood-sugar estimations, two methods were available. In the former the carbohydrate tolerance was first determined, and the diet was then raised to basal requirements by the gradual addition of carbohydrate and fat, insulin being given before the morning and midday meals in the ratio of one unit of insulin to each additional 2 g. of carbohydrate added. In the second there was no period of starvation, and the patient was put at once on a diet which contained protein well within the ½ g. per pound of body-weight; about 20 g. carbohydrate were added, and fat up to one and a half times the available carbohydrate. If glycosuria persisted, small doses of insulin were given until the urine became just sugar-free. Omission of the blood-sugar tests was never wholly safe, but he warned his hearers that the performance and interpretation of these tests required much practice before the results could be depended upon.

The Lister Ward.

The managers of the Glasgow Royal Infirmary have received a further series of appeals for the preservation of the Lister Ward, from a number of corporate medical bodies—British, colonial, and foreign.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

An Open Letter on the Teaching of Sex Hygiene.

THIS year the Interfraternity Conference[1] submits the annual report of its Social Hygiene Committee in the form of an open letter to the faculties of American colleges and universities. It is entitled "An Appeal for the Greatest Personal and Social Health for Students." The letter avoids with scrupulous care the laying down of any fixed standard for teaching sex hygiene, at the same time suggesting some general principles which may be applicable to the various colleges to whom the letter is addressed. Most students, they assert, come to college with very partial and even false notions of the place sex has in normal personal and social life. Many have already entered upon anti-social sex-expressions; others who have really social standards and ideals in reference to sex hold these without intellectual understanding, and accompanied often by unsatisfied emotional tensions. It is certainly futile to enforce dogmatically on such students the orthodox restraints of convention. The Committee believes it to be equally pernicious merely to place before immature and highly sexed young people the biological, psychological, and social facts and theories about sex in a coldly scientific way, and leave them to make an inexperienced and unguided choice of reaction in emotion and conduct. The facts and theories should be taught and sympathetically interpreted. The whole social life and relations of the institution must constitute a practical example of the working out of its ideals. An account is given of various methods that have been used to teach sex hygiene in American colleges. The occasional lecture, though it may have its place, is felt to be quite inadequate to meet the whole need of the students. A unified course, obligatory for all freshman students, is another method. The Committee feels it desirable that such a course be given by one lecturer, whenever a man with the requisite ability can be found. Again, the subject may be naturally introduced into various courses, such as those in biology, psychology, physical education, personal hygiene, English literature, and sociology. Among the "facts and theories" which ought to be expounded are the following: the nature and significance of reproduction, the nature of sex and its relation to reproduction, the influence of heredity and environment upon the individual, the phenomena and explanation of puberty, the relation of sex and its development to emotional, æsthetic, and social life, the evolution of parenthood, the home and family life, true monogamy as the corollary of sex equality, the making of a successful home.

The following are considered to be fundamental fallacies which must be frankly dealt with: (1) That sex intercourse is necessary either to man or woman for perfect sexual development, for bodily or mental health, or for happiness and usefulness. (2) That abstinence is impossible for men. (3) That men have some special rights of indulgence which cannot be allowed to their mothers, sisters, wives, and daughters. (4) That a period of sowing "wild oats" is necessary for the development of sexual control and poise. (5) That continence is a sign of weakness. (6) That a man who has enjoyed a gross sex life can subsequently enjoy completely the happiness of equal democratic marriage. (7) That illicit sex intercourse is at worst an indiscretion. This paper is clearly the result of careful thought and investigation; it deserves consideration by the numerous body of teachers to whom it is addressed. The problem in England may be somewhat modified by the more highly selected character of university students, but it is not impossible that this study might also prove suggestive to English professors and deans.

Public Health Exhibit in New York.

During the week Nov. 5th–12th the U.S. Public Health Service, in coöperation with the American Marine Association, held an exhibit at the Grand Central Palace, New York, demonstrating the health work carried on among American seamen. The exhibit covered some 800 square feet of floor space, and included surgical and dental and X ray equipment, apparatus for hydrotherapy and physiotherapy, a model ship's medicine chest, and so forth. The latter item, designed for a crew of from 40 to 60 men, attracted a good deal of attention. The names of those interested in this chest were recorded, and full particulars will be furnished to them later by the U.S. Health Service. Also a manual entitled "A Ship's Medicine Chest and First-aid at Sea" is said to be now in preparation, and will be mailed to those interested as soon as it is printed.

Lecture demonstrations and first-aid courses have now been established by the Public Health Service in 43 American cities. Medical advice is given by radio upon request from vessels at sea by the stations at New York, Key West, New Orleans, San Francisco, Honolulu, and Manilla. Numerous cases of serious illness have been successfully handled by wireless diagnosis and prescription.

INDIA.

(FROM OUR OWN CORRESPONDENT.)

Cholera in Bombay.

THE cholera epidemic which occurred in Bombay in the rains subsided in the first week of September. 274 cases in all were notified in the months of July and August, and of this number 155 proved fatal. A striking feature in the epidemic was that the number of cases notified daily having risen to an average of 25, fell from 26 on August 2nd to eight on August 3rd, the day on which the amount of bleaching powder added to the city water-supply was increased from 4½ to 7 lb. per hour. From this date onwards the number of cases continued to fall till no further notifications were received. It was a singularly unkind fate which decreed that the results should thus have been too good by a few days only to be true, and too immediate to enable the Health Department to accept without reserve the credit of terminating the epidemic by sterilising the water. Certain features in the outbreak suggested the possibility of water-borne infection. The cases were widely scattered, and in the only ward receiving no water from the lake supply under suspicion no case occurred in July, whilst four only occurred in August. On the other hand, 28 imported cases of cholera, chiefly among pilgrims, had occurred in the city in the month of June, whilst cholera was rife in June, July, and August in districts communicating freely with Bombay. Further, whilst cases were notified by ones and twos in each of the seven wards of the city, epidemic incidence was limited to C ward, where 103 deaths occurred as against a maximum of 16 deaths in the other six divisions. This unequal incidence in wards, mostly supplied from the same source, is against the theory of water-borne infection, but however this may be the water-supply of the city is in the near future to be above suspicion. In 1925 the water from Tansa Lake will be brought throughout its course of 70 miles in closed pipes, instead of passing as at present through 26 miles of a dilapidated masonry aqueduct into which quantities of surface water find their way during the monsoon. Chlorination can be carried out at any time, and a scheme has been prepared for providing the added safeguard of passing the whole of the supply through rapid filters.

---

[1] Secretary, A. Bruce Bielaski, 120, Broadway, New York.

Dengue.

Dengue, a familiar visitant in Calcutta, has till recently been rare in the Bombay Presidency. Early in the year, however, cases began to occur in the city of Bombay, and were followed by a considerable epidemic which has now begun to decline. The disease has also appeared in other parts of the Presidency, in Delhi, and elsewhere. The patients, as usual, find they are by no means out of the wood on the termination of the acute attack, and many suffer from pain in some muscle, tendon, or joint for a number of weeks after resuming their ordinary mode of life. The comparative immunity to the disease hitherto enjoyed by Bombay is difficult to explain, and is in any case not due to any dearth of the reputed carriers—*Stegomyia fasciata* and *Culex fatigans*.

Humidification in Indian Cotton Mills.

A valuable report on Humidification in Indian Cotton Mills by T. Maloney, M.C., has been received by the Government of India. The report shows that even at very high wet-bulb temperatures the body temperature of the workers in mills does not at the end of a day's work rise any higher than it does among workers in other trades under better conditions. Fatigue and a consequent fall in efficiency is, however, well marked at the end of the day. Whilst the physique of the average mill-hand is poor, that of the weavers, contrary to expectation, was found to be better than that of workers employed in other departments under less trying atmospheric conditions. This is probably due to the fact that those of poor physique cannot stand the strain of work in the weaving rooms. Weight decreases after a few months' continuous service in a mill, and apart from actual signs of tangible injury to health there is abundant evidence to show that the workers suffer from subjective sensations of discomfort and distress. As to the practicability of reform it is of interest to note that in one mill run on model lines, notwithstanding the tropical climate, the temperatures compare favourably with those often recorded in some English mills during the summer months.

Housing.

The annual report of the Development Directorate shows that their vast housing scheme for the city of Bombay has made good progress. Out of 50,000 one-room tenements to be provided, 2720 in 60 new buildings were let or ready to let on March 31st, 1923. For the relief of congestion several square miles of land are to be added to the city by the reclamation works now advancing rapidly in Back Bay. On account of the deplorable epidemics of malaria which have in the past accompanied reclamation works in Bombay itself and elsewhere, the operations of the Directorate in Back Bay naturally give rise to a good deal of anxiety. To allay the apprehension felt and to forestall danger, the Government has appointed an advisory sanitary committee to work in close touch with the officer selected by the Directorate to organise anti-mosquito and other sanitary measures over the whole of the areas to be reclaimed. That the situation is well in hand may be judged from the report recently presented by Lieut.-Colonel S. R. Christophers, I.M.S., Director under the Government of India of the Central Research Institute at Kasauli, who has been permitted by the Government to advise as to the precautions to be taken. In the concluding paragraph of his report Colonel Christophers says: "I think the position of the committee in regard to the control of malaria on the reclamation area is sound. Under present arrangements it is practically impossible that any serious increase in anopheles could arise without this being at once fully appreciated, and should such increase occur I see no reason to doubt that effective measures could be at once found to deal with it."

Small-pox.

Except for the recent occurrence of a few cases of small-pox, serious infectious disease is at present practically absent in the city of Bombay. The death-rate remains low, and should no untoward event occur in the next six weeks, the rates for the year, despite the cholera epidemic, should, according to Bombay standards, be satisfactory.

Bombay.

The Services.

REWARD FOR GALLANTRY.

Surg.-Comdr. William Perceval Hingston, R.N., has been appointed a Member of the Military Division of the Third Class, or Companion of the Most Honourable Order of the Bath, in recognition of the gallant conduct he displayed and the valuable services he rendered on the occasion in September last of the destruction by earthquake and fire of the R.N. Sick Quarters, Yokohama, when by his gallantry and presence of mind he was the direct means of saving the lives of the large number of refugees who sought escape from the fire in the hospital grounds.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Capt. Sir R. Bankart, medical officer of the Royal Yacht *Victoria and Albert*, to be Surg.-Rear Admiral.

Surg. Comdr. E. D. Rutherford is placed on Retd. List at own request.

Surg.-Lt. Comdrs. to be Surg. Comdrs.: A. B. Clark, G. B. Cockrem, M. R. Thatcher, E. St. G. S. Goodwin, G. D. Mackintosh.

Surg. Lt. (Emergency List) A. G. Bee is reinstated on Active List.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. A. L. Scott and Maj. C. Cassidy retire on ret. pay.

Capt. P. G. Tuohy retires, receiving a gratuity.

Temp. Capts. relinquishing their commns. and retaining the rank of Capt.: F. M. Davies, M. Ferguson, and R. R. H. Wonnacott.

Capt. B. C. O. Sheridan relinquishes the actg. rank of Maj.

Temp. Capt. L. H. Walsh relinquishes his commn. and retains the rank of Capt.

MILITIA.

Capt. J. B. Irving relinquishes his commn. and retains the rank of Capt.

ROYAL AIR FORCE.

Flight Lt. W. J. G. Walker is granted a permanent commission.

R. W. White is granted a short service commission as a Flying Officer.

Correspondence.

"Audi alteram partem."

RESPONSIBILITY OF THE CRIMINAL LUNATIC.

To the Editor of THE LANCET.

SIR,—The Report of the Committee upon Insanity and Crime cannot be said very appreciably to have clarified the difficulties it was constituted to consider. Without doubt several of its members were at least sympathetically inclined to accept the medical case, but unhappily this case was not presented by a united voice. The result will probably be that a widely diffused but mild satisfaction will be felt by the mass of the two professions concerned; while the general public, so far as in cold blood and uninfluenced by any immediately outstanding case in point it is at all concerned, will be indifferent. The medico-psychological world will welcome a further diminution of the field of criminal responsibility, and the legal world will, perhaps, be somewhat, though not seriously, apprehensive that "the observance of the law" may further "be gravely hindered" by the inclusion of such nebulous mental material as impulses "which the prisoner was by mental disease in substance deprived of any power to resist."

In the Middle Ages insanity afforded no legal defence. In 1670 the great lawyer Hale wrote that partial insanity is no excuse, and it is really only within the last hundred years that, with the growth of humanitarianism in the administration of the law and of psychology in the practice of psychiatry, the problem of defining responsibility has become prominent. The solution of the problem certainly becomes no easier as the years move on. On the one hand, the importance of the doctrine of inescapable personal responsibility becomes clearer as the scientific investigation of ethics, law, and sociology becomes more profound. Without it even our language would have to be remodelled. On the other hand, the analytic investigation of the evolution of the mind, whether in the race or in the individual, shows more and more that growth depends upon factors over which the individual can be said to have but slight, if any, control.

It is with those considerations before him that the physician so often appears to the lawyer to be unduly hesitant in the question of responsibility. Few will be found to disagree with the committee "that a person may be of unsound mind and yet be criminally responsible," but the difficulty of the physician at once arises when he attempts to disentangle the unsoundness and the responsibility. In practice he finds it impossible, and, perhaps inclining too much to the merciful and too little to the judicial aspect of the case, passes to the position that it is better to excuse any accused person who presents any symptoms of insanity than to punish one whose act has, in fact, been the result of morbid mental processes, although the connexion between the act and the processes is not obvious, or rational, or even likely.

Much of our difficulty and controversy really depends on the unscientific treatment of most of our criminals and the irrevocable character of punishment. To hang a man as an act of retribution or as a warning to others for an act for which he was not responsible is clearly contrary to the ethical sense of our civilisation. To condemn him under similar circumstances to a term of imprisonment, though not so revolting, is calculated to burden the general conscience. It is likely that in the future the notion of mitigated responsibility will become more prevalent. The bald problem of whether a criminal is responsible or not will be exchanged for the problem as to how far heredity, education, and environment have qualified his responsibility, and sentences will vary with the findings of an examination of these factors. Punishments in their turn are likely to be compounded less of retributive and preventive elements and more of the corrective or ameliorative element. Changes of this character will, of course, take time to become widely operative, but in the meanwhile the medical profession may think with pleasure that such changes of a scientific character are slowly but surely making their appearance, and are due almost wholly to the work of its members.—I am, Sir, yours faithfully,

Harley-street, Dec. 2nd, 1923. E. D. MACNAMARA.

GENERAL ELECTION: THE ENFIELD SEAT.

To the Editor of THE LANCET.

SIR,—Local considerations and conditions led me to the decision *not* to contest the Enfield division at this election, thereby making a three-cornered contest; but I have been asked, and have agreed, to be the prospective Liberal candidate for the next election.

I am, Sir, yours faithfully,
R. LESLIE RIDGE.

Enfield, Middlesex, Nov. 29th, 1923.

NASAL SINUSITIS IN PHTHISIS.

To the Editor of THE LANCET.

SIR,—I do not think the citation of Skillern by Dr. A. L. Yates (THE LANCET, Dec. 1st, p. 1211) tells for his contention that frontal and ethmoidal sinusitis do not complicate the diagnosis of chest affections; for Skillern's conclusion was that ordinary maxillary sinusitis was not over-common in tuberculosis. Moure's conception of nasal defect in phthisis I mentioned deprecatingly in my letter as well as in my book; but also with the implication that it was far nearer the truth than the proposition that these nasal changes are the result of tuberculosis, which is what Dr. Yates had advanced. As to packing the nose of ozænatous consumptives with cyanide gauze, that was merely on a single occasion, "for an hour or so," to remove crusts, deodorise, and abate the nuisance to fellow sanatorium patients. The above indicate differences real enough, but such as will diminish. If Dr. Yates publishes his protocol, he will add to the scanty exact record, and thereby to our knowledge.

I am, Sir, yours faithfully,
Dec. 2nd, 1923. W. C. RIVERS.

MATERNITY NURSING HOMES.

To the Editor of THE LANCET.

SIR,—In connexion with the efforts of the medical profession to lower both the present existing high mortality and illness from puerperal sepsis, may I call attention to one of the types of maternity home which are springing up like mushrooms throughout the country, especially in the poorer areas of the large cities. The public, in response to the teaching of the profession, is beginning to appreciate the advantages that accrue when a confinement is properly conducted in a well-equipped institution or nursing home. With the demand the supply has naturally increased, but it behoves the profession to watch carefully that the good is not undone by new evils arising in its midst. I refer to the small dirty house, owned and presided over by a woman frequently covered by the diploma of the C.M.B., into which patients are taken for the purpose of their confinement. Houses of this type are popular with the masses, and apparently are a financial success to the owner. No medical man enters unless something goes wrong, and then it is often too late. The midwife, however, is "covered" because she has called in medical help.

It is no uncommon thing in the out-patient department of a hospital to trace many cases of pelvic inflammation to the "care" bestowed upon the patients in houses of this type. It is one thing to train a woman for the diploma of the Central Midwives Board. It is another to train her, without long and detailed hospital experience, to equip and manage a maternity home. As often as not it is the uneducated type of the C.M.B. diplomée who appears to fall into the error of attempting such a proposition.

The result is that the "maternity home" of this type is nothing more than an ordinary dirty house in which one or more women wear uniforms, and where repeated vaginal examinations are made at considerable risk to the unfortunate patients, who pay for the mythical security which the blessed word "home" suggests. Instances have been brought to my knowledge of places of this description where no temperatures are taken, catheters are not available, and even where septic patients—e.g., inoperable carcinoma—are being attended by the same woman.

How can this state of things be altered? It is a difficult matter for obvious reasons for an individual practitioner to act, especially if a "home" of this type happens to be in his immediate district. Cannot a solution be found in the inspection and possible registration of all maternity nursing homes and institutions where pregnant women are taken for the purpose of their confinement? Periodical inspection would be no hardship, and, from information that I have obtained, would be welcomed by homes of repute. At the same time it would put an end to that other type of home run purely as a financial concern at the expense of the health of the mothers of the nation.

I am, Sir, yours faithfully,

Beckwith Whitehouse,
Honorary Obstetric Officer, General Hospital,
Birmingham: Examiner to the Central
Midwives Board, &c.

Nov. 27th, 1923.

A CORRECTION.

To the Editor of The Lancet.

Sir,—In a lecture which I delivered this week as Gresham Professor of Physic before the National Union of Teachers upon Fatigue and Sleep, I am reported to have said that I had discovered a vaccine which I was using to combat fatigue. This, of course, is wholly inaccurate and has caused me much annoyance. I read my lecture from a carefully prepared manuscript. I referred to the work of Drs. Myers, Stanley Kent, and Vernon, as also to that of Mosso, Crile, Cannon, Miss May Smith, and others. I pointed out that fatigue was probably caused by the accumulation of intra- and extra-neuronic toxins; but that the body had power to form "antibodies," or antitoxins, to combat these; and if ever their nature could be ascertained, a vaccine might not impossibly be prepared to antagonise the feelings associated with fatigue. No press notices were submitted to me.—I am, Sir, yours faithfully,

Robert Armstrong-Jones.

Bramham Gardens, S.W., Dec. 1st, 1923.

Donations and Bequests.—By the will of the late Sir Albert John Hobson, of Sheffield, the testator left such part of his promised gift of £5000 to Sheffield University as has not been paid, together with any duties payable thereon, to the said University.—The Chelsea Hospital for Women and the Bolingbroke Hospital each receive £100 under the will of the late Mr. A. F. Hall of Battersea.—Mr. S. Bunning of Borrowshaw, who started life as a railway porter at Derby and afterwards was manager of a brewery at Beeston, Nottingham, walked into Derby Infirmary and handed the secretary £1000 in notes to endow a bed in memory of his late wife. He then visited the Railways Servants' Orphanage and left notes for £670.—Mr. Samuel Maurice Marcus, the triple millionaire of Redhill, Surrey, left £10,000 to the Reigate and Redhill Hospital, £5000 to Guy's Hospital, £1000 each to the London Hospital, Dr. Barnardo's Homes, Royal Institution, London, and Jewish Board of Guardians.—Dr. John William Pare, M.D., L.D.S., of Golders Green and Cavendish-square, left estate of the gross value of £23,472. Failing issue to both his daughters he left £1000 to the Royal Society of Medicine, upon trust for investment, and to apply the income in support of any investigation for the advancing of the art of healing, this fund being named the Margaret Edmondson Pare and Arthur Henry Pare Trust; £500 to the University Court of the University of Edinburgh, for the medical faculty of that University, provided that his name be permanently associated with this bequest; and £500 to University College Hospital, London, for the dental department, with a similar provision as to the association of his name.

Medical News.

University of Oxford.—The following candidates satisfied the examiners in the recent examination for the Diploma in Public Health:—

Part I.—J. G Johnstone, A. A. E. Newth, H. Shannon, and A. C. Tibbits.

Part II.—W. H. Butcher, H. W. Hardy, A. A. E. Newth, H. Shannon, A. C. Tibbits.

Society of Apothecaries of London.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—J. B. Couche, Toronto; J. E. Elam, Cambridge and St. Bart.'s Hosp.; S. Halperin, St. Thomas's Hosp.; J. B. Sweet, Glasgow; and S. Thompson, Leeds.

Medicine.—J. E. Elam, Cambridge and St. Bart.'s Hosp.; E. J. R. MacMahon, St. Thomas's Hosp.; W. McLaren, Durham; D. Parsons, Charing Cross Hosp.; and L. Statnigrosch, Middlesex Hosp.

Forensic Medicine.—J. E. Elam, Cambridge and St. Bart.'s Hosp.; and D. Parsons, Charing Cross Hosp.

Midwifery.—P. V. Casling and E. J. Creais, St. Mary's Hosp.; J. E. Elam, Cambridge and St. Bart.'s Hosp.; E. J. R. MacMahon, St. Thomas's Hosp.; W. McLaren, Durham; I. Morgan, St. Mary's Hosp.; D. Parsons, Charing Cross Hosp.; F. R. Ratnagar, Guy's Hosp.; M. A. E. Somers, Bristol; J. B. Sweet, Glasgow; and E. W. Warne, Guy's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: J. E. Elam, S. Halperin, D. Parsons, M. A. E. Somers, and S. Thompson.

University of London: *London Inter-Collegiate Scholarships Board.*—Eleven medical entrance scholarships and exhibitions of an aggregate total value of £1134, tenable in the Faculty of Medical Sciences of University College and King's College, and in the medical schools of King's College Hospital, University College Hospital, the London Hospital, and the London (Royal Free Hospital) School of Medicine for Women are being offered. The examinations will commence on April 28th and June 24th, 1924. Full particulars and entry forms may be obtained from the secretary of the board, Mr. S. C. Ranner, M.A., Medical School, King's College Hospital, Denmark Hill, London, S.E. 5.

Small-pox in England and Wales.—Cases of small-pox occurring during the week ended Nov. 24th were reported in the following sanitary areas: Derbyshire 9 (Chesterfield 1, Heanor 6, Blackwell R.D. 1, Shardlow R.D. 1); Gloucestershire 11 (East Dean R.D.); Notts 16 (Hucknall 12, Kirkby-in-Ashfield 3, Basford R.D. 1); Yorks W.R. 1 (Bentley-with-Arksey); Port of Cardiff 1.

Tuberculosis Society.—A meeting will be held on Dec. 14th, at 8 p.m., at the Margaret-street Hospital, Margaret-street, London, W., when a paper on Operative Fixation for Caries of the Spine will be read by Mr. R. Milne.

West Kent Medico-Chirurgical Society.—A meeting of this Society will be held at the Miller General Hospital, Greenwich, on Friday, Dec. 14th, at 8.45 p.m., when the Purvis Oration will be delivered by Sir Thomas Horder on Carcinomatosis.

The Inheritance of Mental Defects.—An illustrated lecture on this subject will be held on Dec. 13th, at 8 p.m., at Essex Hall, Strand, W.C., by Prof. E. W. MacBride, F.R.S., under the auspices of the Society for Constructive Birth Control and Racial Progress. Dr. Marie Stopes will preside.

Irish Medical Schools' and Graduates' Association.—The autumn dinner was held at Pagani's Restaurant, London, on Nov. 27th. Sir William Taylor presided, the guest of the evening being Surgeon Vice-Admiral Joseph Chambers. Over a hundred members of the Association and friends were present and an enjoyable evening was spent. The next dinner will be held on St. Patrick's Day, March 17th, 1924.

Society of Medical Officers of Health: Maternity and Child Welfare Group.—Dr. Harold Scurfield will deliver his presidential address, entitled Lines of Advance in Maternity and Child Welfare Work, at 5 p.m., on Dec. 14th, at 1, Upper Montague-street, Russell-square, London. W.C. Medical practitioners interested in maternity and child welfare work are invited to be present.

Royal Institution.—At a general meeting held on Dec. 3rd, Sir James Crichton-Browne being in the chair, it was announced that Mr. Joseph Barcroft, F.R.S., has been elected Fullerian Professor of Physiology in succession to Sir Arthur Keith. Special thanks were returned to Dr. Rushton Parker for his donation of £100 towards the improvement of the library.

Sir Humphry Rolleston has accepted the chairmanship of the Propaganda Committee of the National Association for the Prevention of Tuberculosis.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—A meeting will be held at the Elizabeth Garrett Anderson Hospital on Dec. 11th at 8.30 P.M., when Dr. Agnes Savill will read a paper on the Sun Cure at Leysin.

AT the close of the Brussels Cancer Conference on Nov. 23rd, it was decided to organise an international association to fight cancer, with Dr. F. M. Bergonié, professor of biological physics at Bordeaux University, as chairman of the provisional committee.

THE King has sanctioned the following appointments to the Order of the Hospital of St. John of Jerusalem in England: Lieut.-Colonel Gerald Hamilton Goddard, R.A.M.C., Dr. Hugh Falconer Oldham, and Lieut.-Colonel William Booth Skinner, S.A.M.C., to be Knights of Grace.

GRAPHIC METHODS IN HEART DISEASE. — Two lectures, illustrated by lantern slides, will be delivered on this subject by Dr. John Parkinson on Dec. 17th and 19th, at 4.30 p.m., in the Anatomical Theatre of the London Hospital College. The lectures are free and are intended for senior students of the hospital and post-graduates.

MEMORIAL TO THE LATE PROF. DELÉPINE.—A bust in bronze, by Mr. John Millard, of the late Prof. S. Delépine, of the University of Manchester, will be unveiled by Sir George Newman at the Public Health Laboratory, Manchester, on Dec. 12th. The bust will be placed in a marble niche on the staircase of the laboratory.

CANCER HOSPITAL.—A course of post-graduate lectures will be delivered at the Cancer Hospital (Free), London, S.W., weekly during the months of January, February, and March, 1924, dealing with various aspects of cancer. Any registered medical practitioner or student who wishes may attend, without tickets. The syllabus of the lectures will be published later.

ROYAL NORTHERN HOSPITAL. — On Nov. 27th H.R.H. the Prince of Wales opened the new casualty department at the Royal Northern Hospital, which is the borough of Islington's war memorial. The new building, with equipment, cost nearly £16,000, and of this sum £12,000 has been already subscribed through the efforts of the Islington War Memorial Committee, the corporation, and many individual helpers.

INDUSTRIAL HYGIENE.—With a view to contributing towards the study of occupational diseases and industrial health the International Labour Office undertook some time ago to draw up a list of unhealthy occupations. This entailed the examination of a large amount of statistical, chemical, and medical information, the publication of which has been approved, as it is considered likely to be of great value to medical men and to all persons interested in labour questions. The intention is to publish, under the title Occupation and Health, a complete encyclopædia of industrial health and pathology, which will give the reader the most recent and carefully checked information at the disposal of an international organisation. The articles dealing with industrial poisons, infectious diseases, and the general account of matters relating to poisoning and infection, to personal health, sanitation, and medical treatment will be published first. There will follow short monographs on the industries likely to injure the life or health of workers. The final series will discuss general questions of industrial physio-pathology. A number of experts from all countries have already promised to collaborate in this work, and it seems likely that the publication of their collated experience will prove of considerable importance.

NATIONAL TEMPERANCE LEAGUE. — Sir Thomas Barlow, first medical President of the League, was welcomed by a representative body of members and associated temperance workers in the Council Chamber of Caxton Hall, Westminster, on Nov. 30th, when he delivered an address dealing with Prof. E. H. Starling's recent book, "The Action of Alcohol on Man." He pointed out that it departed from impartial presentation by the general implications made in favour of the ordinary use of alcohol on grounds other than scientific. Alluding to the loss the League had sustained by the death of its oldest vice-president, Dr. Clifford, the President referred to the fact that some 35 years ago he had examined Dr. Clifford for life insurance, and stated that Dr. Clifford's policies had more than doubled in value before maturity. Brief speeches were made by the Bishop of Croydon, Lord Clwyd, Mr. W. McAdam Eccles, Mr. Arthur Evans, and Dr. Basil Price, testifying to the regard felt for Sir Thomas Barlow, and congratulating the League on its new President.

THE HARBEN LECTURES, 1923.—These lectures will be delivered in the theatre of the Royal Institute of Public Health (37, Russell-square, London, W.C.1) by Prof. D. Levaditi, M.D., Institut Pasteur, Paris, on Tuesday, Wednesday, and Thursday, Dec. 11th–13th, at 5 P.M. The subjects of the three lectures are: (1) Neurotrophic Virus (Encephalitis Herpes); (2) Neuro-vaccine; (3) New Discoveries in the Treatment and Prophylaxis of Syphilis. The lectures will be delivered in English, and all interested are invited to attend.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Dec. 10th.

WAR: at 5 P.M.
Paper:
Surg.-Commander D. H. C. Given, R.N.: An Inquiry into the Causes Underlying the Mosquito Nuisance in the Alvestoke (Hants) District, and the Initiation of Measures of Control.
A discussion will follow.

Tuesday, Dec. 11th.

ANNUAL DINNER of the Society, Hotel Victoria, London, at 7.30 P.M.

THERAPEUTICS AND PHARMACOLOGY: at 4.30 P.M.
Papers:
Prof. F. R. Fraser: Some Aspects of Cardiac Dyspnœa.
Dr. Claude Wilson: The use of Opium in Cardiac Dyspnœa.

Wednesday, Dec. 12th.

PSYCHIATRY: at 8.30 P.M.
Paper:
Dr. W. L. Templeton and Dr. Henry J. MacBride: The Malaria Treatment of G.P.I.

Thursday, Dec. 13th.

NEUROLOGY: at 8.30 P.M.
Paper:
Dr. F. L. Golla: Electromyographic Studies of Voluntary Movements.

Friday, Dec. 14th.

CLINICAL: at 5.30 P.M. (Cases at 5 P.M.)
Cases:
Dr. Neil Hobhouse: Progressive Neural Muscular Atrophy.
Dr. Bernard Myers: Adiposis Dolorosa.
Dr. C. F. T. East: Congenital Morbus Cordis.
Other cases will be shown.

OPHTHALMOLOGY: at 5 P.M., at the Central London Ophthalmic Hospital, Judd-street, W.C.
Clinical meeting.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. 1.

MONDAY, Dec. 10th.—8–30 P.M., Discussion on Intracranial Hæmorrhage in New-born Children, its Pathology, Effects, Treatment, and Results. To be introduced by Mr. Eardley Holland and Dr. H. Charles Cameron, and followed by Dr. Farquhar Buzzard, Mr. Laming Evans, Dr. Sidney Owen, Mr. H. A. T. Fairbank, Dr. J. B. Mennell, Dr. L. G. Phillips, and Dr. E. Bellis Clayton.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THURSDAY, Dec 13th.—At 8.15 P.M. a Laboratory Meeting will be held at the London School of Tropical Medicine, Endsleigh-gardens, Euston-road. The following, amongst others, will give demonstrations: Major R. G. Archibald: A New Protozoön in Man. Surg. Rear-Admiral Sir Percy Bassett-Smith: Scurvy in Guinea-pigs. Dr. W. Broughton-Alcock: Exudate from a case of Spirochætal Catarrh of the Antrum. Major T. L. Bomford, I.M.S.: Trichonocardiasis of Hair. Dr. R. St. John Brooks: Post-mortem Appearances of Meliodiosis in Guinea-pigs (slides of the Causal Organism *B. whitmori*). Dr. J. T. Duncan: The Effect of "Bayer 205" in Kala-azar. Colonel S. P. James. M.D.: The Parasites of Inoculated Malaria in England (in General Paralytic Patients). Mr. B. Jobling: Life-History of Ornithodorus Monbata. Colonel Clayton Lane, M.D.: Direct Centrifugal Flotation for the Accurate Concentration of Ankylostome Eggs. Dr. P. H. Manson-Bahr: Pel-Ebstein Disease. Dr. P. H. Manson-Bahr: Living Embryos of *Loa loa* Stained by Sharpe's Method in vivo. Dr. H. B. Newham: A Series of Malaria Slides from British Honduras. Dr. Graham Willmore: Rare Streptothrical Infection of Liver and Kidney. Dr. H. M. Woodcock: Rickettsia Bodies from Normal Lice.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE, 1, Wimpole-street, W.

Monday, Dec. 10th, to Saturday, Dec. 15th.—Hampstead General Hospital, Haverstock-hill: Special Intensive Course (second week).—Royal Westminster Ophthalmic Hospital, Charing Cross: Clinical Instruction every afternoon from 2 p.m.; Tuesday and Thursday at 10 a.m.—St. John's Hospital (London School of Dermatology): Clinical Demonstrations twice daily at 2 and 6 p.m.; Saturday, 2 p.m. only.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday, Dec. 10th.—10 a.m., Mr. Maingot: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 2 p.m., Mr. Addison: Surgical Wards.

Tuesday.—10 a.m., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Dr. Burrell: Chest Cases. 2 p.m., Mr. Banks-Davis: Nose, Throat and Ear Dept.

Wednesday.—10 a.m., Dr. Saunders: Medical Diseases of Children. 12.15 p.m., Dr. Burnford: Medical Pathology. 2.30 p.m., Mr. Donald Armour: Surgical Wards.

Thursday.—10 a.m., Dr. Grainger Stewart: Neurological Dept. 11 a.m., Mr. Simson: Gynæcological Demonstration. 2 p.m., Mr. MacDonald: Genito-Urinary Dept.

Friday.—10 a.m., Mr. Dudley Buxton: Dental Dept. 11 a.m., Dr. McDougal: Electrical Dept. 2 p.m., Mr. Sinclair: Surgical Out-patients.

Saturday.—9.30 a.m., Dr. Burnford: Bacterial Therapy. 10 a.m., Dr. Saunders: Medical Diseases of Children. 10 a.m., Mr. Banks-Davis: Operations on Throat, Nose and Ear.

Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departments.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

Tuesday, Dec. 11th.—5 p.m., Dr. A. Whitfield: Fungus Infections.

Thursday.—5 p.m., Dr. W. Griffith: Eczema.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

Thursday, Dec. 13th.—5 p.m., Mr. L. G. Phillips: Tumours Complicating Childbirth.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

Wednesday, Dec. 12th.—4 p.m., Mr. H. T. Herring: The Disposal of the Dead, with Special Reference to Cremation.

THE PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, Oxford-street, W.

Eight Lectures on the Mind and What We Ought to Know About It, at Hamilton House, Mabledon-place, W.C.

Wednesday, Dec. 12th.—6 p.m., Seventh Lecture, Dr. W. A. Potts: Crime and Delinquency.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES.

Tuesday, Dec. 11th.—(At the Royal Infirmary.) 3.30 p.m., Mr. Kerr: Nasal Polypi.

Friday.—(At the Royal Hospital.) 3.30 p.m., Mr. Garrick Wilson: Injuries in the Neighbourhood of the Elbow-Joint.

MANCHESTER ROYAL INFIRMARY.

Tuesday, Dec. 11th.—4.15 p.m., Dr. A. H. Holmes: Demonstration of Cases.

Friday.—4.15 p.m., Mr. S. R. Wilson: Recent Improvements in Anæsthesia.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES.

(At 3.30 p.m.)

Monday, Dec. 10th.—(At the Hospital for Women.) Dr. Leith Murray: Some Points in Gynæcological Diagnosis.

Tuesday.—(At the Maternity Hospital.) Miss Ivens: Indications for Cæsarean Section.

Wednesday.—(At the St. Paul's Eye Hospital.) Mr. Thos. Stevenson: Clinical Cases.

Thursday.—(At the St. George's Skin Hospital.) Dr. F. H. Barendt: Skin Cases.

Friday.—(At the Eye and Ear Infirmary.) Mr. Lethart: The Modern Treatment of Chronic Middle-ear Disease.

Appointments.

Alexander, J., M.B., B.Ch. Belf., has been appointed Resident Surgeon to the Londonderry Infirmary.

Galbraith, A. L., M.B., Ch.B., House Surgeon, North Lonsdale Hospital.

Griffiths, G. B., M.R.C.S., L.R.C.P. Lond., Medical Director of Prisons, to be one of the Commissioners under the Prison Act, 1877.

Lumsden, H. F., M.B., Ch.B. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Lyme Regis District of the County of Dorset.

Phillips, J. W. G., F.R.C.S. Eng., L.R.C.P. Lond., Chief Resident Medical Officer, Lake Hospital and Poor-law Institution, Ashton-under-Lyne.

Taylor, R. J. O., M.B., Ch.B., D.P.H. Edin., Resident Medical Officer, Wandle Valley Joint Hospital.

King Edward VII. Hospital, Cardiff: Jones, A. M., M.D. Edin., F.R.C.S. Edin., Hon. Assistant Surgeon to the Ear, Nose. and Throat Department; and McFarlane, J., L.R.C.P. & S., L.D.S. Eng., and Spiridion, C., L.D.S. Eng., Hon, Dental Surgeons.

Vacancies.

For further information refer to the advertisement columns.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—Asst. P. 50 guineas.

Birmingham Orthopædic Centre (Ministry of Pensions).—Two Jun. M.O.'s. Each £350.

Blackburn and East Lancashire Royal Infirmary.—Third H.S. £250.

Bristol General Hospital.—Hon. Clin. Assts. Sen. Res. M.O. £250.

Burton, Devonshire Hospital, Derbyshire.—Asst. H.P. £150.

Cancer Hospital, Fulham-road, S.W.—H.S. £100.

Colonial Service, British Guiana.—Three Asst. Govt. M.O.'s. £500.

Derbyshire Royal Infirmary, Derby.—Two H.S.'s. Each £200.

Eastbourne, Princess Alice Memorial Hospital.—Res. H.S. £175.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Two Cas. O.'s. Each £120.

General Lying-in Hospital, York-road, Lambeth, S.E.—Res. M.O. £100. M.O. for Infant Welfare Centre.

Hellingly, East Sussex County Mental Hospital.—Visiting Ophth. S.

Johannesburg, South African Institute for Medical Research.—Asst. Pathologist. £800.

London Homœopathic Hospital, Great Ormond-street, W.C.—Asst. P. for Dis. of Women.

London Lock Hospital, 91, *Dean-street, W.*—Clin. Assistantship.

London Lock Hospital, 283, *Harrow-road, W.*—Second H.S. £150.

Manchester Royal Infirmary.—Hon. Ophth. Surg. Sen. Med. Reg. £150.

Middlesex Hospital and Medical School, W.—Eight Registrarships. Each £300.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. P. Also Res. M.O. £200.

Northampton General Hospital.—Hon. Surg. to Ear, Nose, and Throat Department.

Royal Army Medical Corps.—Commissions.

Royal Free Hospital, Gray's Inn-road, W.C.—Asst. P.

St. Bartholomew's Hospital, Venereal Dept.—Pathologist. £300.

St. Peter's Hospital, Henrietta-street, Covent Garden, W.C.—Clin. Assts.

Salford Royal Hospital, Manchester.—Res. Surg. O. £200.

University College Hospital, Gower-street, W.C.—Tuberculosis O. £300. Radiographer.

Walthamstow, Wanstead, and Leyton Children's and General Hospital.—Res. H.S. £150.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S., and Res. Cas. O. Each £100.

Wigan Infirmary.—Third H.S. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments at Beccles (Suffolk) and Lynton (Devon).

Births, Marriages, and Deaths.

BIRTHS.

Healy.—On Nov. 26th, at West View, Paignton, the wife of Dr. Healy, of a son.

Lankester.—On Nov. 28th, at Green Trees, Smith-lane, Bradford, the wife of Ralph Lankester, M.D., of a son.

Wells-Cole.—On Nov. 30th, at Minster-yard, Lincoln, the wife of Dr. Wells-Cole, of a son.

MARRIAGES.

Archer—Ashweek.—On Nov. 29th, 1923, at the Garrison Church, Shoeburyness, by the Rev. L. Alford, C.F., George Eric Archer, M.B., Ch.B., second son of the late Rev. George Archer and Mrs. Archer, of Huddersfield, to Frances Kate, daughter of Captain and Mrs. W. F. Ashweek, of Shoeburyness.

Fyffe—Leetham.—On Nov. 27th, at St. James's Church, Piccadilly, Major Eric Leigh Fyffe, M.B., B.S. Lond., R.A.M.C., to Florence Evelyn (Eve), second daughter of Mr. and Mrs. Alfred Leetham, of Shelley, Holgate, York.

DEATHS.

Elam.—On Nov. 30th, at New Barnet, Herts, William Henry Elam, F.R.C.S.

Latchford.—On Nov. 29th, at Normanhurst, Falmouth, Lieut.-Colonel John Latchford, R.A.M.C. (retd.), aged 78.

Orr.—On Nov. 21st, at Brand House, Ludlow, Shropshire, William John Orr, M.B.Glasg., F.R.C.S. Edin., aged 49.

Pollard.—On Dec. 1st, at Devonshire-place, Birkenhead, George Wilfred Pollard, M.D., C.M.

Thompson.—On Nov. 28th, at Bombay, Francis Barrallier Thompson, M.R.C.S., L.R.C.P., late Chief Medical Officer, Cyprus.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

WORKS OF REFERENCE.

THE MEDICAL DIRECTORY.

The Medical Directory for 1924 reaches us with even more than its usual promptitude; we received it before the month of November was out. The eightieth annual issue of this classic contains the well-known features with the little additions of arrangement and convenience which experience continues to suggest. The numerical summary of the medical profession shows a total of 47,608 names, being an increase of 1297 on the previous year—unprecedented during the last decade. This increase is divided among all sections of the Directory, being especially noticeable in Scotland and abroad; the number of names, however, in the Services section is slightly diminished. The preliminary chapter on British spas and climatic health resorts has been expanded to occupy 24 pages, with the addition of an index. The only new feature is the inclusion of a Directory of the Principal Medical Trades, occupying four pages and including headings such as Abdominal belts, trusses, elastic stockings, and other surgical appliances; Chemists and druggists (manufacturing); Surgical instruments, hospital furniture, water beds, bedsteads, &c. In this section some of the names are indicated in grander type than others. The Late List of new names and changes of address has been transposed to the front of the Directory. All these things make for a useful work of reference which will, indeed, be almost ideal for its purpose when its editors see fit to reinstate the asterisk which for so many years differentiated between information known to be up-to-date and that which has not been subjected to recent revision. The Directory is published by Messrs. J. and A. Churchill and costs 36*s.* net.

THE MEDICAL YEAR BOOK.

We have received from Messrs. William Heinemann (Medical Books), Ltd., a copy of a new work of reference for 1924 intended to serve as a guide to the current activities of the medical profession in the United Kingdom. It is edited by Mr. Charles R. Hewitt, who was associated intimately for 38 years with the literary needs of medical men, first as assistant librarian of the Royal College of Surgeons, and later as librarian of the Royal Society of Medicine. His recent experience has been that of librarian and registrar at the League of Red Cross Societies in Geneva. The book opens with a calendar of forthcoming meetings, beginning with Oct. 1st, 1923, although the volume only reached us on Dec. 1st. There follow in orderly sequence details of the Ministry of Health, the General Medical Council, the Examining Boards, the University of London and its constituent schools, and a list of London specialists, followed by a similar information for other parts of England and for Scotland. In the lists of staffs of hospitals no distinction is made between those on the active and the consulting staff, and there are several ways in which this might cause inconvenience. Information is given of the various services including that of prisons. There is a register of medical societies—Ireland is included here but not elsewhere in the volume—and of nursing homes and nursing associations. Wills of medical men and charitable bequests are noted, and a complete list is given of medical works and pamphlets published in Great Britain during the year preceding publication. The names of current medical periodicals are set out, with prices and address of offices, and libraries where they can be consulted are indicated. The inclusion of days and hours of attendance at the chief London hospitals is another time-saving device—in this case it is the patient's time that can be saved. An adequate index renders cross-reference easy. We commend the general arrangement of the academic section of the book without hesitation, since it follows the familiar model of the annual Students' Number of The Lancet. Mr. Hewitt modestly admits omissions on the ground of the complexity of the work and it would be churlish to complain of these. But we should like to see included those elusive names of the staff of the medical department of the London County Council and those of provincial medical officers of health, although no doubt some of them appear under the heading of hygiene specialists. We miss the mental deficiency hospitals of the M.A.B., and any mention of such useful matters as medical defence and hospital savings associations. It seems a little questionable whether the panel system does actually now "do away with the need for a capital sum at the outset" of a medical career. Every name appearing in the medical records of the book is that of a legally qualified and registered practitioner, but Mr. Hewitt has included in a trade directory (which is numbered and indexed as part of the volume) a list of osteopaths and bone-setters which will prove more useful to the pre-patient and perhaps to the discontented ex-patient than to the medical man himself, who might have been grateful for a list of experienced manipulators willing to act under his personal guidance. The Year Book is concise and pleasant to handle, and is a welcome addition to our works of reference. The price is 12*s.* 6*d.*

THE MEDICAL WHO'S WHO.

To the Editor of The Lancet.

Sir,—I should be grateful if you would permit me to remind practitioners who have not returned their forms to do so immediately as the seventh edition of the Medical Who's Who (1924) is being passed for press. May I repeat that cuttings from, or mere references to, other publications cannot be accepted (unless re-written on the special form provided) without infringement of copyright. In some instances forms have been received with either no name or merely initials and with no address; such, obviously, cannot be printed. If forms have been lost or mislaid another can be sent on receipt of stamp.

I am, Sir, yours faithfully,
The Editor.

1, Chichester House, Chancery-lane, London, W.C. 2.

A BOOK FOR CHILDREN OF ALL AGES.

We are indebted to Mr. Kenneth Walker and Mr. Geoffrey M. Boumphrey for discovering, reproducing, and interpreting certain pictures, "ill-drawn and perished with age," which are alleged by the very oldest tortoise at the Zoo to represent hitherto unknown events connected with Noah and his Ark. "The Log of the Ark" (London: Constable and Co. 1923. 7*s.* 6*d.*) includes an account of the world before the flood, of the coming of the rain, and of the arrival of the birds and animals. The first day on board, the difficulties about baths and breakfast, and the daily life in fine and in dirty weather are described in happy and fantastic vein. But under all the disconnected episodes, described in a whimsical style reminiscent now of Carroll, now of Kipling, runs a connected argument which is both original and dramatic. "Many years ago when the world was new and clean" luscious fruit formed the staple diet of all living creatures. But after the flood the world which gradually reappears to the animals peering anxiously from the Ark is stark and barren of vegetation. During the weary hours on board a subtle and malignant influence, embodied in the "scub," has been causing unrest by anticipations of the commissariat difficulties that will arise in the new world, and by hints at horrible ways in which these might be solved. New desires, fears, and suspicions pervade the Ark, and at the last it is a worried and uneasy Noah who, with the help of the competent Japhet and Ham, organises the disembarkation. Children too young to be stirred by this sinister change of atmosphere will be entranced by the designs on the paper wrapper and elsewhere, and by the accounts of the adventures of the Luminous Puffkins, the Clidders, and not least the Wumpetty Dumps. It is, indeed, a book for children of all ages.

SCOTTISH RESURRECTIONISTS IN 1825.

A correspondent writes: The paragraph on Body-Snatching and Murder, under the general heading Medicine and the Public in the Centenary Number of The Lancet (p. 699), calls particular attention to the Burke and Hare episode in the life of the Edinburgh anatomy schools. Body-snatching in Scotland was no new thing when in October, 1826, 33 human bodies in casks, labelled grimly "Bitter Salts," were discovered on the quays at Liverpool. They were destined for the Edinburgh anatomists, but it would be unfair to infer that those distinguished men drew their supplies from England alone. Burke and Hare conducted their operations in Edinburgh itself, where, till they were apprehended in 1828, they supplied Knox's anatomy school with a succession of corpses. Scotland stood in great fear of the resurrection men, and this is manifest in the stern old Greyfriars Churchyard, Edinburgh, where the "mortsafes" or barred tombs add to the general gloom of the scene, or in the burial ground at Crail, where there is a house "for securing the dead." Scotland, indeed, would seem to have encouraged the resurrection men in their gruesome trade, partly because her anatomy schools have always been famous and then lacked material for human dissections, partly also because her kirk-yards were often far removed from human habitation and unprotected. In the far past her lonely dead were dug up by the swarming wolves, and this probably led to the burials in lake islands. Tradition records this custom to account for the burials on the Isle of Handa, off the coast of Sutherland.

"There are plenty of subjects to be got here in the Highlands," writes Dr. A. C. H. to Joshua Brookes, who was collecting material to form his anatomical museum in 1825, "for there are churchyards without churches and very distant from any house." The passage suggests: "There's a pump: don't put him under it." The letter, if published, might certainly have become an incitement to a system of body-snatching, but Brookes seems to have kept it to himself. It remains in dim and dirty-looking manuscript. "I should suppose also," continues the writer cheerfully, "that from the great bodily exertion which the Highlanders are accustomed to in climbing their mountains, they will be capital subjects for demonstrating the muscles. Besides, the facility afforded for conveyance by steamboats" (then a new invention, which could be put to various uses) "is such that nothing would be more easy than to supply the whole London school from this quarter." It would be interesting to know whether, before the Anatomy Act of 1832, there were indeed any Highland corpses in the London dissecting rooms. That foreign visitors to, or denizens of, London were sometimes the victims of the resurrection men is sufficiently proved by the case of the Italian boy, Carlo Ferrari, murdered by Bishop and Williams, and brought to Partridge's dissecting-room in 1831.

Joshua Brookes was in constant communication with the resurrection men, from the "civil and well-conducted" Mr. Naples, author of the "Diary of a Resurrectionist," the original of which is in the library of the Royal College of Surgeons, to the very desperate ruffians, some 200 in number, who formed the rank and file of the body-snatching brigade. He quarrelled frequently with these men, apparently refusing them—for he was scarcely a rich man, though a very busy anatomical teacher—the douceurs and bribes they periodically demanded. Brookes's London sources of supply being thus unsatisfactory and his need for subjects great, he may possibly have thrown out hints to his distant correspondents that he would be glad of a supply from their parts of the country. Hence, perhaps, the curious letter quoted above and dated in a non-committal manner "West Highlands."

THE HEAD TROPHIES OF THE JIBARO INDIANS.

IN November, 1922, Sir John Bland-Sutton, in an address delivered before the Royal Society of Medicine,[1] called attention to the shrunken heads which constitute the war trophies of the Jibaro Indians. An account of these remarkable objects has just been published by Dr. Rafael Karsten in a paper on Blood-Revenge, War and Victory Feasts of the Jibaro Indians of Eastern Ecuador.[2] Dr. Karsten has added a number of details to our previous information, both as to method of preparation and the beliefs and ceremonies which are connected with these heads.

As regards the method of preparation, the head is severed as near the trunk as possible. A ceremony then takes place in which the head is placed on a leaf of a species to which magical properties are ascribed, and covered with another. The taker of the head then places himself on this "seat," and juice of tobacco and saliva are blown through his nose by the chief. If more than one warrior has participated in the taking of the head, all go through the ceremony in turn. This is to protect them against the revengeful spirit of their slain enemy. The preparation of the head then begins. The skin is slit at the back of the head from the apex downwards, and is carefully stripped from the skull. The skin is then attached to a vine and boiled. A ring of creeper is made for the neck, and the back of the head sewn up with thread. The actual reduction is effected by means of hot sand introduced at the aperture of the neck, but before that is done, the shrinking is begun by the use of three stones heated in a fire and introduced each in turn into the head and rolled to and fro within it. The object of this is to mortify the soul of the killed enemy, which is believed to be attached to the scalp, and keep it at bay. That this process is purely ceremonial is shown by the fact that it is repeated later at the great feast (which every taker of a head has to give) when it can have no practical aim. In the process of reduction sand heated in a piece of broken clay is poured into the head until it is half full. The head is kept in motion so that the sand may act equally on all parts. This removes the flesh, thins the scalp, and reduces the head. When the sand cools it is poured out and the inside of the head is scraped with a knife to remove the charred matter. This is repeated until the head is reduced to the size of an orange. While the process is going on, the head and features are moulded by the hand to retain their human semblance. Three small pins of *Chonta* palm, painted red and wound with red-painted cotton, are passed through the lips, but these are replaced at the great feast by three red-painted strands of cotton. Lastly, the whole face is dyed with charcoal. Particular attention is paid to the hair, which may be half a metre long. It is the most essential part of the trophy, and is believed to be the seat of the soul. At each stage of the preparation of these shrunken heads there are appropriate ceremonies which serve to throw light on the mentality and beliefs of the Jibaro. The head itself is an object charged with supernatural power. The pins or string passed through the lips are explained by the Indians as designed to prevent the heads from cursing them—an explanation alluded to by Sir John Bland-Sutton—but it is more than probable that their real aim is to keep the "soul of the enemy under magical control."

The heads of enemies of another tribe only are taken. The shrinking of a head to form a war trophy is a deadly insult to the whole tribe to which the victim belongs, and it is therefore explicable that they should avoid performing the operation upon anyone with whom blood kinship might be claimed. It is also significant of their stage of development that they take the heads of animals, in particular of the sloth and jaguar, and treat them in the same way. Their explanation of this is that all animals were once men—the sloth belonged to a tribe other than the Jibaro, and therefore was an enemy, and the jaguar was a sorcerer. When the animals were men they fought among themselves and made trophies of heads, and the Jibaro keep up the practice in the case of certain animals. It may be noted that the sloth is killed with a lance just as a man is killed, and the same purificatory rites are enjoined upon his slayer as would have been had he killed a human enemy.

JEYES' VAPORISER.

THE Jeyes' Sanitary Compounds Co., Ltd. (64, Cannon-street, London, E.C. 4), in addition to their well-known and useful preparations of Cyllin, Lano-Cyllin, and Lysol (Jeysol), have produced a Vapor Jeyes for use in generating a non-poisonous and non-irritant vapour for the relief of catarrhal affections. The vapour may also be used for the disinfection of sick rooms and other similar purposes. The preparation is devoid of unpleasant odour and has a guaranteed Rideal-Walker coefficient of 8–10. For its use a simple, but effective, vaporiser is supplied consisting of a metal cylinder in which water is heated by means of a night-light, the Vapor Jeyes being placed in a shallow dish over the top of the water. The simplicity and portability of the apparatus are commendable.

THE LEITZ CATALOGUE.

FOR the excellence of their microscopes and microscope accessories Messrs. Ernst Leitz, of Wetzlar, enjoyed in this country before the war a great and well-deserved reputation. If they have been able under post-war conditions to maintain the level of their workmanship as they have maintained the level of excellence in their catalogue, they have done well indeed; for their new catalogue is praiseworthy both in substance and in form. To one small point exception may be taken. In discussing their high-power objectives they say "in the resolution of minute structural elements, where the image results solely from the effects of diffraction the numerical aperture plays a very important part." We should have thought that the exploded Abbé theory, from which its author receded before his death, had been, by this time, so much discredited by the criticisms of Rayleigh, Wright, and others that it could no longer serve even the purposes of advertisement. But Messrs. Leitz seem to think otherwise, and where it is a question of the market value of pseudo-science we cannot presume to set our opinion against theirs.

LIVINGSTONE COLLEGE.

IN the annual report of the College for 1922–23, which has just been issued, it is stated that during its 31 years' existence the College has trained 752 students (excluding those entering for short courses), of whom 482 remain at work. The greater proportion of the old students are working in parts of Africa, India, and China, where the invaliding and death-rates are the highest of any mission field. As indicated in the report in THE LANCET (1923, i., 1291) of the Commemoration Day gathering on June 13th, it is hoped that the College will take a by no means inconsiderable part in the application of new remedies for the amelioration and cure of leprosy. The Committee noted with satisfaction Sir Leonard Rogers's statement that the College could be of great use in training men and women to help in this work in districts where no doctor is available. The promise of a marked increase in the number of students during the year was not realised. Political unrest and commercial depression have lessened the resources in money of the missionary societies, and fewer recruits are being admitted and sent out. Sixteen missionary societies were represented amongst the students taking the course during the year 1922–23, when eight entered for the full session, six for six months, and eleven for three months or less. Twenty-three entered for the vacation course in July, from 12 societies, and, in addition, 37 students have taken the short course on "Personal Care of Health in the Tropics." The report includes notes written by former students now working in Bechuanaland, East India, Rhodesia, and Nigeria, testifying to the value of their short medical training at the College. The balance deficit of the institution has been reduced to £1109, but the Committee hope for continued and increased subscriptions, which should be sent to the Principal, Livingstone College, Leyton, London, E. 10.

SURGICAL RUBBER GLOVES.

FROM Messrs. J. G. Franklin and Sons, Ltd. (Birkbeck Works, Birkbeck-road, and 11–17, Colvestone-crescent, London, E. 8), we have received a sample of surgeons' rubber gloves which possess great strength and flexibility. They are seamless and the surface, while pliable and soft, is just sufficiently roughened to give a firm grip. Apparently no expense has been spared by the manufacturers in the production of the gloves, which are of British manufacture and made of the finest Para rubber. For surgical and post-mortem work they possess the qualities desirable in articles of this kind.

THE WELSH MEDICAL CURRICULUM.

WE have received from the Registrar of the University of Wales a copy of the calendar for the academic year 1923–24, containing amongst other things the text of the University charter, the names of authorities and office-bearers, the pass-lists of examinations for degrees, certificates, and diplomas in 1923. Physiology is now a final honours subject at University College, Cardiff, and a pass-list in medicine, surgery, and obstetrics appears for the first time; also, for the first time there are lists of diplomates in public health and in tuberculous diseases. We learn that at a University Court, held in Welshpool on Nov. 23rd, the proposal to pledge medical graduates in the University of Wales by declaration to professional rectitude was carried by a large majority.

THE ST. DUNSTAN'S CLINICAL THERMOMETER.

WE have received a clinical thermometer in a special case which is sold under the name of St. Dunstan's Clinical Thermometer. It is made by Messrs. J. J. Hicks and Co. (8, 9, and 10, Hatton-garden) for the inventor and patentee, Dr. McDonnell, who has offered to devote half of the profits accruing from the sale to the funds of St. Dunstan's, an offer which has been accepted by the authorities of that institution. Notable features are that it has a special case which is not larger than that of the ordinary thermometer, but which is ingeniously made so as to contain any desired disinfectant and yet be non-leakable. The outer metal case is incomplete at one spot showing an inner glass tube which contains the disinfectant. Inside this glass tube is a small rubber band which protects the bulb of the thermometer by keeping it away from the sides of the case. The top end of the thermometer has a vulcanite cover which serves as the cap closing the tube containing the disinfectant. We have used the specimen sent to us, and have found it a satisfactory and convenient instrument. The price is 6*s*. 6*d*.

COLONIAL HEALTH REPORTS.

Gibraltar.

THE Colonial Secretary (Major C. W. J. Orr, C.M.G., R.A.), in his report for 1922, estimates the total civil population at 17,327, of whom 16,182 are fixed residents. These figures, it is explained, represent the population between sunset and sunrise; to calculate the daily population it would be necessary to add some 8000 aliens and 1500 British subjects resident in the neighbouring Spanish town of La Linea who come into Gibraltar daily. The birth-rate in 1922 was 22·67 and the death-rate 17·54 per 1000. The general health and sanitary conditions during the year were excellent, and, with the exception of an outbreak of influenza of a mild nature, there was no disease in epidemic form. The general climate is mild and temperate, though somewhat hot and oppressive during the months of July and August. The meteorological record for 1922 shows 70·6° F. as the mean maximum temperature, the highest shade temperature being 95° on August 7th and the lowest 42° on March 23rd. The rainy season spreads over the period from September to May; the annual average rainfall is 35 inches.

British Guiana.

A report for 1922, signed by Mr. G. Ball-Greene, Assistant Colonial Secretary, states that the colony remained free from epidemic disease and the general health was good. The estimated population on Dec. 31st was 297,817 (150,987 males and 146,830 females). The birth-rate was 27·8 and the death-rate 29·1 per 1000. The rates amongst the several races representing the community were:—

	Birth-rate per 1000.		Death-rate per 1000.	
Europeans other than Portuguese	7·9	16·6	17·0	24·2
Portuguese	19·7		26·7	
East Indians	28·1		32·7	
Chinese	28·4		22·6	
Aboringes	30·2		26·2	
Blacks	27·0		28·5	
Mixed races	33·3		19·3	

The climate is hot, but not unhealthy. The mean temperature throughout the year is 80·50° F., the mean maximum being about 85° and the mean minimum 75°. The heat, which is greatly tempered by cooling breezes from the sea, is felt most from July to October, owing to the partial cessation of these breezes. There are annually two wet seasons, from June to the end of August, and during December, January, and February. The annual rainfall for the past 72 years averages about 93 inches in Georgetown; in 1922 it was 104·41 inches.

Barbados.

According to the census taken in 1921 the total population of Barbados, the most easterly of the West Indian islands, was 156,312, of whom 10,429 were described as whites, 111,677 blacks, and 34,216 as "mixed." The following table shows the birth- and death-rates for the past five years:—

	Birth-rate per 1000.	Death-rate per 1000.
1918	38·02	25·95
1919	33·94	38·21
1920	37·07	32·90
1921	32·62	43·42
1922	34·33	22·41

There has hitherto been no registration of the causes of death in the colony, but the high death-rate recorded in 1921 is attributed to an outbreak of typhoid fever in that year. Barbados is reputed the healthiest of all the West Indian islands, and is much patronised by residents in the neighbouring colonies as a health resort. The anopheles mosquito is not found in the island. This is a somewhat curious fact, since it is certain that they must be imported not infrequently in vessels which in many cases lie in the "Careenage" or inner harbour for considerable periods, on arrival from places where they are prevalent. The conditions, however, are evidently unfavourable to their breeding ashore. The hot and rainy season lasts from the beginning of June to the beginning of November. The island gets the full benefit of the north-east trade-winds, and between November and May the night temperature sometimes falls as low as 64° F. For the greater part of the year the temperature is delightfully equable, and the heat is seldom oppressive. The winter months are regarded as the "tourist season." The average rainfall for 1922 was 54·55 inches, varying in different parts of the island from 42·87 inches to 70·90 inches in the higher lands. The heaviest fall in a separate month was in September—12·04 inches.

MECHANICAL APPLIANCES FOR CRIPPLES.

Mr. Gabriel Bidou is an engineer who has devoted many years to the perfecting of mechanical appliances which enable crippled individuals to stand and walk. Although primarily a mechanician, Mr. Bidou shows a due appreciation of the psychology of the cripple, and is not unmindful of the many effective mechanical devices which have been inspired or actually designed by members of the surgical profession. In a recently published little book [1] he has put together a useful account of the various materials employed in the construction of appliances, together with a description of accurate methods of measuring and fitting. As might be expected from a member of the author's profession, the whole problem is approached from a mathematical basis. A full description with illustrations is given of the various types of apparatus used by the author for patients suffering from paralysis, amputations, and deformities. The question of mechano-therapeutics and curative occupations is dealt with very fully. The book has an introduction by Prof. Babinski, who is obviously a great admirer of the work of this ingenious engineer. Its title is perhaps a little misleading, as we find some difficulty in admitting the author's claims that his methods are entirely "new." In this country, at least, appliances of a similar type have been employed by orthopædic surgeons for many years.

A. A. M.—Epilation by electrolysis appears to be harmless, and it can be rendered painless by local anæsthetic, but this is seldom given for the purpose as its action soon wears off, so that there is not time for removing many hairs. Scarring is very slight, and not noticeable unless a number of hairs close together, as in the ordinary beard or moustache, are all removed; then there remains a slight degree of puckering of the skin. Discoloration is not produced by electrolysis. It would be possible to epilate over a large area by removing one hair at a time, but the process takes an exceedingly long time. In actual practice electrolysis is advisable only in cases in which the hairs are stout and not close together; or in cases where there is a small bunch together, as seen, e.g., in some moles, or in some cases in which there are some more evident and dark hairs situated among finer ones—the more evident ones would then be removed. Fine hairs, even if long, are very difficult to remove permanently.

An Address
ON
TRAUMATIC NEURASTHENIA.

Delivered to the Oxford Medical Society on Nov. 9th, 1923.

By E. FARQUHAR BUZZARD, M.D. Oxf.,
F.R.C.P. Lond.,
PHYSICIAN TO ST. THOMAS'S HOSPITAL.

The subject of my address is one which, for a variety of reasons, should be of interest to everybody. It is constantly before members of our profession as a difficult problem in relation to diagnosis and treatment; it is a source of perpetual annoyance to lawyers whose minds are as confused as are those of their medical brethren in regard to its nature and significance; and it is a matter of economic importance to the community at large in that it occasions an enormous waste of time, energy, and money. Such reasons alone might be sufficient to justify my choice, but there is another which has still more weight. The term, "traumatic neurasthenia" and the uses to which it has been put have brought profound discredit, and, I feel bound to add, in many instances deserved discredit, to our profession. As far as I can see our professional reputation is not likely to be reinstated in the eyes of the public or of the law until every medical man and woman has a clear conception of what is meant by this much abused term, and is able to express that conception in language as lucidly as he or she would explain the meaning of "fractured clavicle" or "gastric ulcer." It is, perhaps, fortunate that we are not often called upon to interpret in public all the terms which are to be found in an index of medical nomenclature. It is most unfortunate that we are frequently asked in public to indicate exactly the meaning of "neurasthenia" and its causal relationship to trauma, and it is a calamity that our efforts to do so should so often evoke derision from the body of the court or judicial witticisms from the bench.

It is only necessary to hear the evidence given in workmen's compensation cases in regard to traumatic neurasthenia in order to understand how difficult it is for the legal profession to take this evidence seriously. In one such instance the following statement was made by a medical man in describing a patient alleged to be suffering from traumatic neurasthenia: "My opinion of this case is that his symptoms are entirely functional. The question is how much of these are genuine. Probably some of the symptoms are genuine, but he is giving way to them." The lay mind must be considerably exercised to find the expert knowledge wrapped up in such an opinion. On the other hand, I confess to have been equally confused by the words I shall quote from a lawyer's letter: "The employer's case is that the man's inability to work is caused by his brooding over the effects of the accident and that he is suffering from weakness of will and a fixed but erroneous idea that he is a chronic invalid. If they establish this proposition, then the court would have power to refuse further compensation. If, on the other hand, this man is suffering from neurasthenia, as we are advised, he is then entitled to a continuance of the compensation." To my mind the employer's proposition affords a definition, although perhaps a crude one, of what is meant by the term "neurasthenia." In other words, I should regard the alternative diagnoses, on the choice of which legal judgment would depend, as meaning one and the same thing. Herein lies the crux of the whole problem, and the cause of the confusion which at present fogs the medical and legal mind. In order to disperse these mists it is essential hat we should establish clearly in the first place the nature of neurasthenia, and secondly the causal relationship between trauma and that condition. It is my purpose to examine critically the facts with which experience has provided us, and to consider whether, as a result of this examination, we can arrive at some scientific and practical conception of what the term "traumatic neurasthenia" really means.

Three Groups of Cases.

Let us begin by recording what experience teaches us in regard to types of neurasthenic patients who attribute their condition to injuries. There are three groups of cases. The first group, which comprises the great majority of cases, can be labelled "anxiety neurosis."

Group 1. "*Anxiety Neurosis.*"—These patients give a history of injury to any part of the body, the head perhaps being the commonest site. They differ in no respect from cases of anxiety neurosis, such as we meet with in ordinary practice without any history of injury, or from the most common type of shell-shock victim met with during the war. They complain of constant "pressure" headache, insomnia, fatigue, giddiness, tremors, inability to concentrate, loss of appetite, and pain and tenderness at the site of injury wherever it may be. When you examine their eyes they blink continually, and each voluntary movement they are asked to perform is carried out feebly, hesitatingly, and perhaps tremulously. Their whole appearance is one of anxiety and misery, but careful examination reveals no evidence of organic mischief.

Group 2. "*Spinal.*"—The second group comprises a much smaller number of patients, but the picture presented is characteristic. It may be labelled the "spinal" or, in more vulgar but descriptive language, the "my poor back" group. The patient invariably walks into your room leaning on a stick in one hand, with the dorsum of the other placed over the lower part of his back. You know at once that the site of his injury is his spine. As a matter of fact many of these patients have suffered only from a sharp attack of lumbago, while making a physical effort in the course of their employment. In addition to their characteristic attitude they often present also the symptoms of anxiety neurosis. Again, examination reveals no sign of organic disease, but there is a superficial tenderness over a great part of the spinal column.

Group 3. "*Hysterical.*"—In this group the anxiety neurosis is often associated with some definite hysterical symptom, such as hemiplegia, monoplegia, paraplegia, &c. These cases are not very common, and their occurrence is immaterial to the question under investigation.

Site and Severity of Injury.

As already stated, the development of neurasthenia has no constant relationship with the site of injury. The nervous symptoms are more likely to follow a blow on the head, or a strain of the back, but they frequently present themselves after an injury to a foot or hand. Direct injury to any part of the central nervous system, therefore, is not necessary for the production of neurasthenia. On the other hand, it is not unreasonable to suppose that the awe with which the lay mind regards an injury to the skull or to the spine may be sufficient to account for the frequency with which such injuries are followed by neurasthenia. The severity of the injury, again, has no bearing on the development of neurasthenia. The latter may follow trivial injuries to the limbs as well as a severe concussion. But there is one exception to this rule, an exception which is not without significance. It is rare to find an injury which inflicts permanent physical disablement on a patient followed by neurasthenia. The man who loses an arm or a leg as the result of a railway accident does not suffer from an anxiety neurosis, unless, of course, he has entirely other reasons for doing so.

So far a consideration of our experience in cases of traumatic neurasthenia allows us to form two definite conclusions. In the first place, the clinical picture of traumatic neurasthenia is identical with that of anxiety neurosis. In the second place, the incidence of neurasthenia on trauma is quite independent of the site or severity of the latter. On what does this incidence depend ? This is a question which we should be able to answer. We have to find a factor which is always present in cases of traumatic neurasthenia, and which is generally absent when trauma is not followed by the neuropathic features we have described.

From what I have already said it would seem impossible to find that factor on the physical side. Any attempt to correlate the part injured or the nature of the structural injury with the evolution of neurasthenia, has been shown by experience to be doomed to failure. Naturally we turn for light in other directions, and the question of the patient's inherent or constitutional reaction automatically engages attention. We may be tempted to seek for and find in each patient suffering from traumatic neurasthenia some evidence of hereditary nervous instability. There can be no doubt that such a proposition is attractive, and that it contains at least the germ of truth. But does it satisfy our minds as *the* factor determining the development of neurasthenia after trauma ? Speaking for myself the answer is in the negative, willing as I am to allow it its legitimate due.

The Question of Responsibility.

Having given this question much thought, and having seen and studied quite a large number of patients suffering from traumatic neurasthenia, I have come to regard one factor as having a more profound influence than any other in determining the advent of neurasthenia after trauma. I refer to the question of responsibility. Is the patient responsible for the injury, and has he to shoulder the burden of its results, or can he shift that responsibility and that burden on to others ? Auto-responsibility or hetero-responsibility ? If the latter is to hand then we have the initial preparation of the soil favourable to the growth of neurasthenia. We love to shift responsibility, and, having done so, we have leisure and liberty to study the injury in detail and all the results which it entails. More than that, we are ready to shift the responsibility for recovery on to others, and tacitly to reserve to ourselves the right of determining the length of the illness. What a difference there is between slipping and falling downstairs, due to our own carelessness, and doing the same thing as the result of a push. The emotion of anger and the sense of injury are added to physical discomforts, and are more than likely to prolong disablement. I do not think I am exaggerating the importance of hetero-responsibility, when I submit that it prepares the ground for the crop of nervous symptoms following trauma, but I must offer you some evidence on this point.

Accidents and injuries are among the commonest incidents of everyday life, and certainly not more than one in a thousand is followed by neurasthenia. In the course of years of practice I have seen a large number of cases to which one could apply the name "traumatic neurasthenia," but I cannot recall one in which the responsibility for injury has not been placed away from the patient. These patients have been workmen's compensation cases, railway accident cases, motor accident cases, soldiers, sailors, &c. ; employers, insurance companies, railway companies, and the State have supplied the responsibility. Let us take another sphere of action in which accidents, trivial or severe, are frequent—i.e., the hunting field. It is true that one occasionally sees a patient from this source who presents features resembling those of traumatic neurasthenia, but they are always cases of neglected concussion, never cases of injury to other parts. Moreover, such cases are easily cured, whereas traumatic neurasthenia is almost proverbial for its resistance to treatment.

But if hetero-responsibility prepares the soil, whence come the seeds ? In order to learn something about traumatic neurasthenia, as in all forms of neurasthenia, you must let your patient talk, you must encourage him to recall every detail of his accident and all subsequent events. He will tell you many things which, apparently unimportant, have great significance. There you will find your seeds.

A Typical Story.

Let me describe the sort of story you will hear. Smith is injured in an accident occurring in the course of his employment. The accident took place in such a way that it caused a considerable emotional disturbance—that of fear. This is often called shock, but is distinct from surgical shock. The injury caused pain, and the doctor on examining him said : "By Jove, you have had a narrow squeak ; an inch to the left and the blow would have broken your back." A restless night during which he remembers that there were only three men doing what ought to have been done by four. This gives rise to the sense of injury. His employers are responsible for his suffering. A mate comes to see him a day or two later, and reminds him that Jones had a somewhat similar accident and was dead within a year. (It is immaterial from their point of view that Jones died of influenza and pneumonia.) His wife is a plucky woman and sympathetic, also much incensed against the employers because of the neglect to supply sufficient labour for the job. She makes him comfortable at home, in spite of shortened means. His injury is really slight, and after going to the hospital or his doctor twice a week, for two or three weeks, there is no physical disablement. But the seeds which were planted have grown, and will continue to grow, with the result that you soon have a condition of anxiety neurosis in full bloom. If the doctor said he had had a very narrow squeak, it is obvious that he must have been very seriously injured, and he could not be well in a month. Even if he appeared well there was always the possibility that something else would develop. Did it not in the case of Jones ? It must be remembered that to the lay mind trauma is still the most important and universal ætiological factor in medicine, just as it was in medical text-books 50 years ago. A pain here or a pain there is sufficient to keep him on the alert for complications and sequelæ. Fear and anxiety keep him awake at night, and so the vicious circle is formed. Beneath the surface all the time is the knowledge that his employer was responsible for making him ill, and is still responsible for getting him well. Yes, he will go into hospital for treatment, but under protest. He will come out of the hospital worse than he went in, and more convinced thereby that the injury he received was far more serious than other people, particularly the insurance officers, realised. Weeks, months, and, perhaps, a year or two pass by. He has either become incurable or is tempted by a lump sum of money in full compensation of all his claims. Accepting this, he has, unwittingly, resumed responsibility for his health, and sooner or later health is restored to him.

The case of Mr. Robinson, however, is rather different. He was in a train returning from business when a collision occurred. He was thrown across the carriage and considerably bruised, and not a little frightened. What with his bruises and fright he had several restless nights, in the course of which he explained to his wife the dastardly neglect of the railway company in allowing an hour to elapse between the collision and his being conveyed to a place of safety. This indignation grows as his bruises and fright disappear. He feels disinclined to return to business, and his doctor has hinted that two or three weeks at the seaside in order to get over the "shock" are advisable. After all the company must pay for this, and it is a long time since he had a good holiday. On his return he is not yet inclined to work, and, meanwhile, the question of how much compensation is due to him has become, and is still, a matter of dispute between his and the company's lawyers. He is given to understand that he is suffering from traumatic neurasthenia, and it is impossible to say when anyone may recover from that disease. Anyhow, the company is responsible not only for the disease, but for financing him until he is well. Litigation threatens, further medical examinations ensue, a sum is offered; shall he accept it? More sleepless nights, and the picture of anxiety neurosis, complicated by the sense of injury, is complete.

Now let us look for a moment at the other side. A hunting man sustains a severe concussion as the result of a fall. His doctor tells him he was within an inch of breaking his neck. He has nobody but himself or his horse to blame, and accepts the medical dictum n the spirit that a miss is as good as a mile. After a few days' rest he is feeling so much better that he wants to know when he may get up, and how long it will be before he can hunt again. Provided he is kept ong enough at rest there will be no neurasthenia. If, on the other hand, he is up too soon, headaches will develop, and he will find he is very easily tired and quite unable to concentrate. A further period of rest would get rid of these symptoms, but neglect of such precautions would probably mean the establishment of a neurasthenic state from which recovery may be slow.

The Seeds of Neurasthenia.

Before turning to other aspects of my subject, let me consider briefly one or two of the seeds of neurasthenia to which I have referred. I purposely brought n the doctor as a seed, because I am convinced that care in talking to patients who have sustained injuries is of the utmost importance from a psychological point of view. Such patients are in a very suggestible condition, and the most trivial remarks of the doctor n attendance are apt to produce lasting impressions. Of this I have had many illustrations, brought out by conversations with neurasthenic patients. My reference to the wife originates from the observation of nsurance doctors, as well as from my own. It is rare to find a traumatic neurasthenia persisting for any length of time unless the woman responsible, be it wife or mother, is above the average in her ability to maintain a comfortable home.

Nothing, perhaps, stands out more prominently than he sense of injury if you indulge in conversation with patients suffering from traumatic neurasthenia. There can be little doubt that it is a psychological actor of much importance in promoting and maintaining the patient's ill-health. It is a vague, intangible disease of the mind, almost a psychic cancer, difficult o eradicate, and calculated to block all recuperative processes. It forms one of the chief obstacles in the path of treatment. There is a wrong to be righted, and until that has been done to the satisfaction of the wronged the latter is not likely to turn his attention away from his injury to the ordinary affairs of life.

Its Prevention.

But having given due prominence to the difficulties of treating and curing a patient with traumatic neurasthenia, let me point out that much may be done to prevent it. It is not a condition found mmediately after an injury; it only exhibits its first ymptoms as the bruises are disappearing, and very ften at a still later period. But it sprouts and grows under the doctor's nose, and if he is quick to detect he noxious weed and alive to the dangers associated with its growth he may successfully nip it in the bud. This, no doubt, is often done by practitioners who are n the habit of studying their patients' minds as well s their bodies, but in many instances the former are eglected. The incipient signs and symptoms may, perhaps, be noted but regarded as outside the sphere of medical attention and as the natural sequence of an njury, attributed to that vague factor "shock." A ttle clear thinking should make one realise that the ffects of shock are most manifest immediately after njury, and tend to disappear slowly or quickly as the ase may be. On the other hand, the nervous ymptoms which we are discussing make their ppearance later and progressively increase as time oes on. A little psychotherapy applied early in hese cases would be far more valuable than lint and andages. As in all spheres of medicine, early iagnosis and appropriate treatment is the secret of uccess.

Two Schools of Thought.

At the beginning of my paper I expressed my belief that the disrepute into which medical evidence on cases of traumatic neurasthenia has fallen was occasioned by the absence of a clear conception of the pathology of that condition. There appear to be two schools of thought. The one favours the view that an injury of any degree of severity and inflicted at any site may produce a physical condition of the nervous system, with characteristic signs but without any morbid anatomy, to which the name traumatic neurasthenia is fairly applicable. The other view, and I submit the true one, is that the signs and symptoms of traumatic neurasthenia are those of an anxiety neurosis, complicated by certain factors to which I have drawn attention, and that it should be regarded as an emotional state, dependent not on any physical disturbance caused by trauma, but on a number of psychological factors. Although the knowledge that an injury has been sustained exerts a powerful influence in the development of neurasthenia, the latter is not the result of trauma. Furthermore, it must be recognised that the power of the influence exerted by the knowledge that an injury has been sustained would be very small unless it were accompanied by the ability to shift the responsibility for the injury and its effects on to other shoulders. It is quite true that there are many physical manifestations present in all severe cases of neurasthenia, and that they may truly be regarded as disabling, but our knowledge of the physical manifestations of the emotions enables one to recognise those of traumatic neurasthenia as those of chronic fear. After all, what is anxiety but chronic fear?

As medical men we are not in any way bound to go further than this. The final decision as to whether a condition such as I have described is to be legally regarded as the result, direct or indirect, of injury must rest with judges who interpret the law of the land.

Legal Problems.

At the present time, according to the letter I have already quoted to you, the courts recognise two conditions, one of which is a mental state characterised by brooding, weakness of will, and fixed ideas, and the other "traumatic neurasthenia" which, having a name, is in no need of further definition. A name is so satisfactory even when it means nothing; it becomes part of the established order of things and discourages all curiosity or investigation. The irony of the present position is that if you suffer from a certain kind of mental disorder following an injury, and it is called traumatic neurasthenia, you are entitled to compensation; but if the judge prefers to describe the identical condition in other language, then you must forfeit your claim. That legal judgment should continue indefinitely to be based on such a confusion of ideas seems hardly possible, but it is difficult to see how reform is to be brought about unless the medical profession becomes united in its opinion as to the meaning of traumatic neurasthenia, and each individual member of it is able to supply an intelligible interpretation of that meaning. What is a judge to do if medical witnesses on one side say that a man is suffering from brooding, fixed and erroneous ideas, and on the other side that he is suffering from traumatic neurasthenia.

The judicial mind is bound to regard the latter diagnosis as that of some dire disease, of which the name is sufficient to indicate its origin from physical injury. He can have no choice, under existing laws, to do anything but continue compensation so long as this, perhaps interminable, disease persists. On the other hand, he can decide that the patient is not suffering from physical disablement, but is brooding and harbouring fixed and erroneous ideas, a decision which enables him to stop compensation. What a quibble! Would not the following judgment cover both cases? I find that Mr. Smith is no longer prevented from working by reason of any injury he may have sustained as the result of the accident, but that he is suffering from an emotional disorder which has its origin in anxiety and other psychological factors. But such a judgment would not necessarily bring the judge's difficulties to an end. Sooner or later it will have to be decided whether compensation can be claimed for a disorder of the mind, call it either neurasthenia or anxiety neurosis, following an injury for which another person or body is responsible, but not resulting from that injury. This question has already, I believe, been a potent source of trouble to the legislators of other countries, and is one which sooner or later must be faced here. It is a question full of snares in which justice and mercy may easily be entangled. The mind of the general public is as yet quite incapable of realising that a condition of ill-health and disablement can be the result of psychological influences alone, and a decision that compensation could not be recovered for neurasthenia following an accident might be the subject of an outcry. On the other hand, a contrary decision constitutes a direct appeal for the development and maintenance of neurasthenia whenever the responsibility for trauma can be foisted on the shoulders of others, and especially when a sense of injury has, rightly or wrongly, been acquired.

These legal problems, however, are not for us to solve. Our duties lie in a different and even more important direction. If we are convinced that traumatic neurasthenia, or "anxiety neurosis following trauma," as I should prefer to call it, is a mental disorder recognisable in its infancy, it is our duty to prevent its development. We must be on the look-out for the earliest symptoms, just as we look out for a rash in a person who has been exposed to measles, and we must be prepared to fight them without delay. We must realise that they are the advance guard of an insidious disorder capable of producing far-reaching results and distressing disablement, and we must be ready to give them battle on their own ground and at the earliest opportunity. Our weapons must not be merely the advice to take plenty of exercise in the fresh air, and a bottle of medicine repeated week after week, but a free expenditure of time devoted to fathoming the contents of the patient's mind, and an honest endeavour to re-establish a healthy mental outlook. Bring the anxieties and fears and misunderstandings to the surface, expose their fallacies, and disperse the germs of revenge and greed.

It is impossible to encourage and reassure successfully an anxious and perplexed patient until you not only understand his fears and difficulties, but have convinced him that you have thoroughly mastered them.

DIAGNOSIS AFTER HEAD INJURIES.

Before concluding, may I say a few words in regard to diagnosis in the case of patients who have suffered head injuries? I refer to patients who have had more or less severe concussion, and who complain of subsequent headaches and mental disabilities in the form of defective concentration, defective memory, depression, fatigue, and so on without any physical signs of disease. It is convenient to approach such cases with the idea of discriminating between three different conditions, each of which has characteristic symptoms and appropriate treatment. I have already referred to the first group to which might be given the name of true traumatic neurasthenia. A member of this group has had a definite head injury with concussion, the severity of which may be roughly measured by the length of retrograde amnesia. He has been kept at rest in bed for an inadequate length of time, and after getting about suffers from headache of the neurasthenic type—that is to say, more or less continuous and described as pressure on the vertex, or as a tight band round the temples. He is easily tired and cannot concentrate, thinks his mind is becoming defective, becomes depressed and anxious, and finally presents the characteristics of a neurasthenic patient. Such cases can be prevented from developing if sufficient rest is prescribed for patients who suffer concussion. They can be readily cured with rest and reassurance provided the responsibility is their own. The second may be described as the "contusion" group. In this case the patient recovers from the effects of his head injury in all respects except one. He finds that every attempt at physical exertion gives him a severe headache which is paroxysmal, not continuous, and more or less exactly localised over the site of injury. This site becomes tender when the pain is present, and sometimes when it is absent. An X ray examination may or may not reveal a bony injury. Not a few of such cases can only be relieved by surgical intervention, and when the skull is opened there is usually found some localised thickening of the meninges, and perhaps a collection of fluid in the subarachnoid space shut off from surrounding healthy parts by adhesions. At the site of bruising the brain has become anchored to the dura mater. The third group comprises the cases of anxiety neurosis following trauma, to which I have already devoted much of your time this evening, and which, as I have pointed out, are able to shift responsibility away from themselves. Their prevention and cure must depend largely on psychotherapeutic measures.

CONCLUSION.

In conclusion, I do not for one moment expect that the views I have expressed will be unanimously accepted. I shall be satisfied if I have provided some food for thought, and if I have established the case with which I opened in regard to the need for some clear thinking on the subject of "traumatic neurasthenia."

SYPHILIS AS A COMPLICATION OF TUBERCULOSIS.

BY A. K. BOWMAN, M.B., CH.B. GLASG.,
ASSISTANT TO THE VISITING PHYSICIAN, EASTERN DISTRICT HOSPITAL, GLASGOW; LATE SENIOR ASSISTANT MEDICAL OFFICER, CITY OF GLASGOW SANATORIUM, ROBROYSTON.

NUMEROUS inquiries have been made as to the incidence of a positive Wassermann reaction (W.R.) among the inmates of institutions specially concerned with the treatment of tuberculosis. The scheme of the present contribution is briefly to summarise the findings of various observers, and to analyse the results of blood examination for the W.R. in 500 patients resident in the City of Glasgow Sanatorium, Robroyston, which, in regard to number of beds—548*—is the largest institution of the kind in Great Britain. These examinations were carried out during the year 1922 as a routine measure on admission of the patients through the tuberculosis dispensaries of the city, the patients being both pulmonary and non-pulmonary and in no sense selected. The effects of antisyphilitic treatment in certain of the cases reacting positively were also ascertained and will be referred to in the last section of the paper.

The general details of the tests carried out are as follows:—

A. Subjects of pulmonary disease:—

No. of sera tested	223
No. of positive reactions	21

Approximate percentage of positive reactions, 9·42.

B. Subjects of non-pulmonary disease:—

No. of sera tested	277
No. of positive reactions	14

Approximate percentage of positive reactions, 5·05.

Previous Recorded Tests.

It has been taught generally that syphilitics are particularly susceptible to infection by the tubercle bacillus, and in 1914 Bronfenbrenner[1] published the results of an investigation into the frequency of tuberculosis in syphilitic subjects. Two tests were carried out. First, by means of Besredka's T.B.

---

* Including 100 beds for convalescent patients in the Auxiliary Hospital, Robroyston.

antigen he examined the sera of 193 syphilitics. Eighty-three cases, or 43 per cent., were found to give a positive reaction for tuberculosis. Of these, 55 exhibited clinical signs of tuberculosis, while in the remaining 28 the latter condition had gone unrecognised. Secondly, for comparative purposes he examined 432 non-syphilitics—or, to be more precise, individuals who gave a negative W R. Of this series, only 100 persons, or 23·15 per cent., gave a positive reaction for tuberculosis. Bronfenbrenner thus concluded that tuberculosis was indeed peculiarly liable to become implanted on a luetic soil.

Tedeschi[2] claims that 70 per cent. of the cases of tuberculosis developing during a period of ten years of his prison service occurred in subjects of syphilis. Such a statement, while giving confirmation to the view that syphilis increases the susceptibility of an individual to tuberculosis, cannot be held as applicable to the general population, for Tedeschi dealt with a special type of patient living under conditions which may be presumed to have favoured a tuberculous invasion. Letulle[3] has recorded that 19 per cent. of 346 tuberculous patients in Bouciecaut Hospital gave a positive W.R. Recently, Munro[4] gave the following analysis of 100 cases investigated at the Fife and Kinross Joint Sanatorium :—

> Number of positive reactions 22, of which 6 (a remarkably high figure) were believed to be syphilis of the lungs ; 11 gave both Wassermann positive and sputum T.B. positive ; 3 were considered to be tuberculosis with W.R. positive and sputum T.B. negative ; and in the remaining 2 the W.R. reaction was positive and the diagnosis other than tuberculosis. Leaving out of account the 6 cases diagnosed on clinical grounds as syphilis of the lungs, there remain 14 per cent. of patients suffering from tuberculosis and giving a positive W.R.

These investigations thus fall into two groups—namely, (*a*) those of Bronfenbrenner and Tedeschi, and (*b*) those of Letulle and Munro. In the former case the question was gone into from the point of view of tuberculosis as a complication of syphilis ; in the latter, as in the present inquiry, syphilis was looked for as a complication of tuberculosis. For reasons already stated, Tedeschi's figures should be excluded from this discussion. Bronfenbrenner's results, however, may be said to stand as positive evidence for the view that a tuberculous invasion is specially favoured by a syphilitic soil. It is extremely difficult to estimate with any accuracy the precise incidence of syphilis among the civil population of this country ; but there appear to be grounds for placing its frequency at between 8 and 10 per cent.† Granting that this proportion is approximately correct, one would anticipate that, if Bronfenbrenner's findings were universally applicable, the proportion of luetic patients among those examined for the present review would be definitely higher than the 10 per cent. or thereabouts found among the general population. The facts do not confirm any such anticipation. If for the moment the 500 cases be grouped together into one unit, it is seen that only 35, or 7 per cent., gave a positive W.R. This figure varies widely from what the work of Bronfenbrenner would lead one to expect ; and the percentage is also strikingly low when compared with the results of Letulle and Munro, those of the latter being at least double 7 per cent.—*at least* double, because, in view of the work of Sir William Osler,[5] Sir James Kingston Fowler,[6] and others, it seems to be unlikely that in a series of 100 cases six of pulmonary syphilis should occur. Further, out of the 277 non-pulmonary patients examined—the great majority of whom were children—only 14, or 5·05 per cent., were found to be syphilitic, the lues in these instances being congenital with two possible exceptions.

It is not suggested that those figures show syphilis to be of less importance in its relationship to tuberculosis than is generally held. It is, however, not unreasonable to suggest that the coexistence of the two diseases may be less common than is frequently stated, and that syphilis may not directly predispose to tuberculous infection. This view is partly supported, among others, by Elliott[7] and Lyons.[8] The latter examined 471 cases of tuberculosis and found that 6 per cent. gave a positive W.R. The former, in commenting upon work done in the hospital of the University of Michigan, states that " 3 to 5 per cent. of our syphilitics have shown evidence of Koch infection." Elliott, however, amplifies his remark by adding that " this low percentage may be explained by the fact that a very large portion of our cases of syphilis are seen in the primary or early secondary stages of the disease. We have found tuberculosis to be more commonly associated with the older syphilitic lesions." This last sentence expressed what would naturally be expected—that the older syphilitic lesions are those most likely to be associated with tuberculosis—since there is nothing to suggest that syphilis is more easily acquired by tuberculous than by normal individuals ; but the results of the Robroyston series of cases, the positives among which were all either late or congenital, give no indication that there is any very peculiar susceptibility of syphilitic subjects to tuberculosis.

The question arises : Is it not highly possible that among the 500 cases examined there occurred a number of luetic individuals in whom syphilis was unrecognised both clinically and by the W.R. ? Cobbett[9] is of opinion that the reaction may be trusted to give as true a verdict as any of the other modern diagnostic tests ; and Sequeira gives the following results of blood examination in patients whose clinical signs pointed to a syphilitic infection :—

Stage.	Positive reaction.
Primary	90
Secondary	99
Tertiary	95
Congenital	100

These figures are substantially similar to those arrived at by other workers, and it may be taken that for practical purposes the W.R. carefully performed can be relied upon, at least in this country, where yaws and leprosy are practically unknown, to give sufficiently accurate knowledge of the prevalence of syphilis in a series of individuals whose blood is subjected to examination. As a matter of fact, in the present inquiry the number of patients in whom either history or certain physical signs were suggestive of syphilis, and in whom the W.R. was negative, was so small as to make no appreciable alteration in the percentages obtained. It may be reiterated, then, that no evidence can be submitted in this paper in support of the view that tuberculosis has a higher incidence among the syphilitic than among the non-syphilitic population.

Mistaken Diagnosis of Tuberculosis.

In respect of the present series the further question now arises : In how many instances did the primary diagnosis of uncomplicated tuberculosis break down on investigation and give place to one of pure syphilis ? Pulmonary and non-pulmonary cases may be considered separately. Practically all observers are agreed that syphilis of the lungs, difficulties of recognition notwithstanding, is rarely found with certainty either clinically or in the post-mortem room. The following extract illustrates the generally prevailing view.[6]

> Kingston Fowler, after a careful inspection of the museums of the London hospitals . . . was unable to find more than 12 specimens which are believed to illustrate syphilis of the lungs, and of these he excluded 2 as very doubtful specimens . . . On referring back to clinical notes of 1323 male patients suffering from various diseases, none of them hospital cases, and of the age of 20 and upwards, 53 cases presented a definite history of syphilis. Out of this number there were 5 cases of lung syphilis . . . On the other hand, out of the same series of cases there were 320 cases of pulmonary tuberculosis, in which only in 3, or less than 1 per cent., was a syphilitic history apparent.

In contradistinction to the above, Munro's investigation led him to the conclusion that 6 out of his 100 cases were clinically syphilis of the lungs. As detailed above, out of 223 pulmonary patients examined at Robroyston, 21, or under 10 per cent., reacted positively. In 10 of these cases syphilis was suspected, either from history or from physical signs; in 11 syphilis was unsuspected. At some time or other while the cases were under observation, either before or during the course of antispecific medication (see below), evidence of tuberculosis, in the form of *B. tuberculosis* in the sputum, was found in all 10 suspected cases and in 9 of the unsuspected cases. Of the remaining two, one, a married woman of 38, refused to remain in hospital. No tubercle bacilli were found during her brief residence and she received no antisyphilitic treatment. The other, an unmarried man of 37, exhibited clinical signs compatible in every way with chronic pulmonary tuberculosis, but no bacilli were ever demonstrated. After a full course of neokharsivan, combined with mercury and iodides, the improvement in his whole condition was so striking as to leave no doubt that a diagnosis of pulmonary syphilis should be substituted for pulmonary tuberculosis. Neglecting the case of the woman referred to above, whose case was almost wholly uninvestigated, this was the only instance in which such a decision could be come to; and the incidence of syphilis of the lungs in the cases under review may thus be placed at something below 0·5 per cent.

---

† Vide Final Report of Royal Commission on Venereal Diseases, 1916.

The non-pulmonary cases are of less interest as regards mistaken diagnosis. Of the 14 cases giving positive reactions, 8 were suspected and 6 unsuspected, suspicion being based upon more or less obvious stigmata. In three instances—two suspected and one unsuspected—the diagnosis of tuberculosis broke down, and that of syphilis was confirmed by the results of treatment. In the others, the two diseases were found to coexist, the latter conclusion being dependent on clinical and X ray examination and on the results of treatment.

Results of Treatment.

If the question of the frequency with which syphilis and tuberculosis are associated in the same individual has been productive of conflicting views, the subject of antisyphilitic treatment in tuberculous patients appears to have led to still greater confusion. On the one hand, certain observers have claimed that very material improvement has followed the exhibition of 606 and its analogues, while others condemn antisyphilitic treatment, arsenical or otherwise, in cases where tuberculosis is known to exist. Disasters in past days have doubtless resulted from intensive mercurial treatment in certain tuberculous cases, and the effects of salvarsan in tuberculosis require the fullest consideration. It is impossible in this contribution to do more than indicate the results obtained during treatment of the present series of cases, and to correlate them with the work of others.

In the first place, the possibility of the one disease exerting a modifying influence upon the other must be borne in mind. That such an influence may exist is recognised. Thus Bonney[10] records the case of a young man with well-developed pulmonary tuberculosis which was quite resistant of treatment until, after the patient's dismissal from a sanatorium, he contracted syphilis and ultimately did well. What therapeutic methods were employed, and whether the outcome may be partially explained by a mutually antagonistic action of the two diseases, are points which are not clear; but that such an action may exist appears to gain in possibility from a detailed review of a number of the cases of the present series. Space is not available for such a review, but a few general indications may be given. Among the pulmonary patients, for example, were four in whom the physical signs suggested very chronic disease of tuberculous origin, but in whom tuberculosis could not be diagnosed with any certainty until, during the course of antisyphilitic treatment, the matter was cleared up by the appearance of tubercle bacilli in the sputum. This demonstration of bacilli for the first time occurred simultaneously with reactivation of varying degree of the disease in the lungs, as evidenced by general and, apparently, focal reactions. A summary of two illustrative cases is given below:—

CASE 1.—Female, aged 29, unmarried; notified T.B. and admitted June 28th, 1921. General condition fairly good, weight 7 st. ½ lb.; slight cough, sputum in very small amount, no tubercle bacilli, physical signs limited to left upper lobe and suggestive of very chronic disease. Syphilis unsuspected until W.R. was found to be positive in November, 1921. Treatment was general up till this point; patient in good condition, weight 8 st. 7 lb.; cough and sputum absent; physical signs practically nil. Commencing on Nov. 22nd, 0·15, 0·3, and 0·45 g. neokharsivan were given intramuscularly in creocamph at weekly intervals. Severe general reaction—headache, sickness, elevation of temperature—followed each dose. In middle of December cough and sputum reappeared and temperature became intermittent, the evening rise becoming gradually and progressively higher. Physical signs became much more marked and many moist râles appeared. Soon it became obvious that aggressive disease had set in, with rapid and widespread infiltration of the left lung and extension to the right. Tubercle bacilli were next found in the sputum in large numbers, and the diagnosis of tuberculosis was confirmed. In April, 1922, patient was transferred to another institution, where she died in the following June.

CASE 2.—Male, aged 51, married; notified T.B. April 6th, 1916; admitted June 28th, 1921. Chronic disease of at least 10 years' standing; general condition poor; very little sputum, in which no tubercle bacilli could be found by any method. Syphilis was suspected from the history, and the W.R. was found to be positive. Two full courses of novarsenobillon were given, each dose being followed by a general reaction, which was at first very slight but which became more marked in time. "Much pain at the top of the right lung" was frequently complained of after the injections—this probably indicating a focal reaction. During the second course of treatment tubercle bacilli appeared for the first time in the sputum, and the patient ultimately left the hospital of his own accord, depressed at being less well than on admission.

Arsenical treatment was given altogether in 17 of the pulmonary cases. In one, its administration permitted of a diagnosis of lung syphilis being substituted for one of tuberculosis; in four, treatment resulted in a certain diagnosis of tuberculosis where doubt had existed previously. There remain 12 cases which were frankly tuberculous from the outset. In seven of these, aggravation of the symptoms occurred either during or after treatment, each case showing definite focal and general reactions—increased temperature, aggravated cough, more abundant sputum, pain in chest, sometimes headache and sickness—after the injections, which in none of these cases were persisted with for more than six weekly doses. Any syphilitic stigmata present cleared up rapidly, but the satisfaction engendered by this was more than discounted by grave and rapid changes in the lungs. Five cases remain to be mentioned. All of these were apparently unaffected by the drug, and there was a striking absence of reaction after the injections. In no case did any special improvement occur, although the patients were living under sanatorium conditions.

As regards the non-pulmonary cases, 12 of the 14 positives were treated. In three of them a primary diagnosis of tuberculosis was upset and gave place to one of syphilis (one skin case, exactly simulating widespread multiple lupus, and two cases of knee-joint disease); in five, no influence of any kind appeared to be exerted by the drug; and in the remaining five there was distinct and progressive aggravation of symptoms and signs. These last cases showed focal reactions after the injections. Where obvious syphilitic lesions were present, treatment was followed by their reduction or disappearance. An illustrative case may be briefly quoted.

CASE 3.—Male, aged 2, notified multiple T.B. May 13th, 1922; admitted Sept. 6th, 1922. On examination child was extremely emaciated and pale; temperature showed slight variations from normal; physical signs, which suggested syphilis, were as follows: Tibial node; swelling over right parietal bone, slightly fluctuant; hard glandular swelling below mandible; swelling over third and fourth right metacarpals. Small doses of mercury and potassium iodide were commenced, and three weekly doses (2, 4, and 6 cg.) of sulfarsenol were given subcutaneously. The injections were followed by restlessness and heightened temperature and only three were given, the other drugs being continued. On Nov. 20th the general appearance was much improved and the cranial and tibial nodes had practically disappeared, but the metacarpal and submandibular disease had progressed rapidly. Both lesions had broken down and were discharging, in spite of repeated aspirations, giving rise to typical tuberculous sinus formation and ulceration, followed by a mixed infection. A fresh glandular swelling had developed in the neck and was softening, and the temperature was widely intermittent and at times remittent. There was now no question that the child was suffering from combined tuberculosis and syphilis.

This case provides a good illustration of what has been referred to as the possible mutual antagonism of the two conditions. According to the statements of the child's parents, all the swellings had remained practically unchanged during the four months which intervened between the date of notification as tuberculosis and the commencement of antispecific treatment; but after eight weeks of the latter, and although the syphilitic lesions had disappeared and the child's appearance was distinctly better, active tuberculous processes were in progress where inactivity had existed before. Necrosed metacarpal bones had to be removed shortly afterwards and the temperature record had become disquieting. A precisely similar sequence of events was seen in a girl of 14 with unilateral knee-joint disease, undoubtedly tuberculous, and with stigmata of congenital syphilis in the form of Hutchinson teeth and a saddle-shaped nose. The disease in the knee-joint appeared long to have been quiescent before the commencement of antisyphilitic treatment, but neokharsivan injections were followed by focal reactions, swelling, softening, and finally breaking down of joint with involvement of the skin and sinus formation. Repeated occurrences of this kind make it difficult to escape from the suggestion that in some cases at least—and perhaps most of all those in which a more or less latent spirochætal infection is present—a syphilitic affection may react favourably on a coexisting tuberculous one, and that the removal or modification of the former by antispecific measures may lead to, or favour, an activation of the tuberculosis. It is impossible, in the absence of histo-pathological data and of any certainty as to the physiological processes initiated by 606, to do more than suggest possible explanations of the phenomena so frequently found to occur, but such suggestions may be of value in so far as they form a basis for future investigation. The direct action on the tissues of the drugs concerned, or the physiological reaction precipitated by their administration, may be responsible factors; but it seems more probable that the true explanation may be found in the condition of the tissues which are exposed to the action, chemical or physiological, of the drugs. It has been found—e.g., in glandular disease—that syphilitic and tuberculous tissues may be intimately intermingled, and it may be that general and focal reactions, and subsequent aggravation of the tuberculosis, are to be explained by the resolution of syphilitic tissue immediately adjacent to tuberculous tissue, the vascular and fixed tissue reactions which occur permitting of ready extension and aggression on the part of the tuberculosis. Absence of reaction might therefore be due either to an entire dissociation of syphilitic and tuberculous tissues, the latter being quite unaffected, or to the existence of a densely fibrotic condition on which no drug can be expected to exert any influence whatever. It would therefore follow that, while syphilis of the lungs as an isolated disease is extremely rare, pulmonary syphilis and pulmonary tuberculosis might be associated in the same patient much more commonly. The reaction following salvarsan would then depend on the condition of the tissues. Should the syphilitic lesion be entirely fibrotic, 606 would lead to little if any focal reaction, and no stimulation of the tuberculosis into greater activity would occur; whereas, if definite absorptive processes followed the injection of the drug, tubercle bacilli might be liberated in great numbers and thus precipitate a serious and even rapidly fatal extension of the tuberculosis.

It is to be emphasised that at Robroyston there was seen in no case anything like the striking improvements recorded by certain writers. For example, Hartley[11] treated with salvarsan 16 patients suffering from pulmonary tuberculosis, and states that in these pyrexia, which had previously resisted all therapeutic measures, yielded rapidly to the drug. This experience is directly at variance with that of the present series of cases, in which pyrexia tended to appear or to increase after the injections were given, and this resulted no matter whether neokharsivan, novarsenobillon, or sulfarsenol was used. The mode of administration appeared to have no influence whatever. Case 1, for instance, was treated intramuscularly by neokharsivan in creocamph, Case 2 by N.A.B. intravenously, and Case 3 by sulfarsenol subcutaneously.

Stopford Taylor[12] describes two cases of lupus—the first consisting of multiple ulcers of the right arm and the other of ulcerating lupus of the face—which responded beautifully to neokharsivan injections. In the first the result was "nothing short of marvellous," which would seem to point to the lesions having been syphilitic in origin, while in the second a speedy change for the better took place after three injections. There is little doubt that distinct focal reactions in tuberculous lesions take place after the injection of organic arsenic, and it is conceivable that, as is the case in tuberculin treatment, the focal reaction may be productive of some good in cases where the lesion is on a free surface, such as the skin, where it can be carefully watched; but too little is known of such reactions, and they have been treacherous too often, to permit of their general application.

In 1911 Herxheimer and Altmann[13] reported a series of cases the results in which receive confirmation from those of the present series. Their cases all showed the same reaction—i.e., any obvious luetic lesions which were present healed under salvarsan therapy, while latent tuberculosis flared up. Wechelmann[14] collected from the literature ten cases of associated syphilis and tuberculosis treated by salvarsan, in all of which death occurred and was attributed by Wechelmann to the exhibition of the drug. Elliott[7] describes 12 cases, supposedly tuberculous, in which various preparations of organic arsenic were administered. In eight of these the result was unsatisfactory; the ninth, lupus involving the chin and the left hand, showed a very marked focal reaction after the injections, but does not appear to have been followed up. The remaining three responded beautifully to the treatment, the general condition showing a marked and rapid improvement and the physical signs clearing up. The diagnosis in these cases was consequently changed to syphilis.

Conclusions.

1. From a consideration of limited data the incidence of a positive W.R. has not been found to be more frequent among the tuberculous than among the general population.

2. Syphilis of the lungs existing as an isolated disease is extremely rare, but it may be that a number of cases recognised as pulmonary tuberculosis and in which the W.R. is positive are in reality cases of combined syphilis and tuberculosis of the lungs.

3. The two diseases when coexistent in the same individual may modify each other.

4. In cases in which syphilis and tuberculosis are present in the same individual, the administration of 606 and its analogues may be followed by disaster. If organic arsenic is used, it should be administered in extremely small doses and at wide intervals. If no disturbance follows the injections, treatment may be continued cautiously, but it should be at least temporarily suspended if focal or general reactions occur and the condition carefully watched.

5. Organic arsenic compounds may be useful in cases in which the diagnosis is doubtful, but it is

unjustifiable to employ them for diagnostic purposes save with extreme care, and always having in mind the possibility of a tuberculous flare up.

I have to make the following acknowledgments: To Dr. John Watson, medical superintendent, Robroyston Sanatorium, for permission to use this material; to Dr. R. M. Buchanan, city bacteriologist, Glasgow, who, in the interests of uniformity, arranged to have the actual blood tests carried out; and to Dr. J. L. Brownlie, of the Public Health Bacteriological Department, Glasgow, by whose labour and kindness the reactions were actually ascertained.

INTRACRANIAL BIRTH INJURIES.[1]

BY H. C. CAMERON, M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN, AND PHYSICIAN IN CHARGE OF DEPARTMENT FOR DISEASES OF CHILDREN, GUY'S HOSPITAL.

IN attempting to deal with the after-history of such infants as survive, let me say that I fully appreciate the difficulties with which I am surrounded. On one side lies all that careful work carried out by our obstetric colleagues, beginning with the exhaustive and patient investigations of Dr. Herbert Spencer, the record of which is tucked away so securely in an old volume of the Obstetrical Transactions that some of us seem to have a difficulty in finding the reference, and ending with the important work which has just been recorded. In other countries, and especially in Germany and the United States, the output of work has been even greater, all of it going to show the frequency of intracranial hæmorrhage in infants born dead or moribund.

Ætiology: Conflicting Views.

The belief that infants surviving this kind of trauma at birth lived to form some part of the total of cases of cerebral diplegia has, in the past, been very generally held. Such was the view for which Little himself pleaded, and since his day it has received the support of Gowers, Osler, and many others. But upon the other side lies another series of researches to which equal attention must be paid. I do not think I am overstating the case if I say that at the present day neurological opinion is averse from the view that intracranial hæmorrhage at birth is responsible for any considerable part of the cerebral diplegia which presents itself in later childhood. Such, I think, was the view which Dr. J. Collier expressed the other day in his presidential address at the Neurological Section of the Royal Society of Medicine,[2] and he there summarised the extensive literature which supports his own observations, that autopsies conducted upon children who have shown during life evidence of cerebral diplegia reveal a condition compatible only with the assumption that the cause was to be found in primary errors of development. The findings of obstetricians and neurologists are, to that extent, opposed and at first sight seem capable of being reconciled readily and completely by one assumption only, that all infants with intracranial hæmorrhage die at birth or in infancy, so that the neurologist whose post-mortem and histological examinations are carried out upon older children is confronted only with those in whom the diplegia is the result of encephalitis or due to developmental defect. Such a view has been advanced. One patient observer (Kowitz), as a result of the study of 6000 autopsies, maintains that the cases of meningeal hæmorrhage occurring at birth are gradually eliminated by death before the end of the third year of life.

If, therefore, I state at the outset that my work among infants and children makes it impossible for me to discard the belief that Little was right in his contention that there exists a certain group of cases of diplegia, recognisable by what he calls "considerable pathological resemblances in intellectual character and physiognomical expression," as well as by a degree of spastic rigidity, which owe their defect to intracranial hæmorrhage at birth, I am confronted at once with the difficulty of producing the necessary pathological proof. Only in one respect is the position changed since Little's day. It was to ask for the production of this pathological evidence that Little, whose interests were largely orthopædic, had himself introduced as a guest at a meeting of the Obstetric Society and gave that clear account of the disorder which he believed to be the result of asphyxia at birth. To-day an immense obstetric literature upon the subject, recently summarised with great clearness in an important work by Ehrenfest, provides in part the answer to Little's request. We now know not only the varieties of intracranial hæmorrhage which may be caused at birth, but we have a clear conception of the immediate symptoms which result in the first days of life.

Symptomatology of Intracranial Hæmorrhage.

The immediate symptoms of large subdural hæmatoma above or below the tentorium or in both situations are well known. In the tense bulging fontanelle there is clear evidence of increased intracranial tension. If pressure upon the fontanelle is made, respiratory distress, screaming, or even convulsions may follow. The cerebro-spinal fluid is often under greatly increased pressure and in most cases contains blood. If the examination is made a day or two after birth there may be evidence of altered blood, staining of the cerebro-spinal fluid, degenerated erythrocytes, &c. The ophthalmoscope has now entered the lying-in chamber, and it is said that 60 per cent. of the cases show retinal hæmorrhages and that œdema of the disc may appear. Inequality of the pupils, squinting, and nystagmus are common. The infants, as a rule, exhibit extreme restlessness and constant screaming, or there may be stupor and immobility. The increased tone of the muscles is very striking in most cases. There may be generalised rigidity with opisthotonos, trismus, clonic twitchings of individual muscles or groups of muscles, or generalised convulsions. If any part is stimulated with a slight flick, a characteristic violent twitch of the whole body results. But that which indicates most clearly the serious state is the impairment of the two reflexes vital to the child, the sucking reflex and the breathing reflex. The breathing may be slow and stertorous, or it may be rapid and shallow, or there may be ominous pauses in which the pulse continues to beat strongly. Some degree of asphyxia is the rule in all severe cases. Suction is not only poor and clumsy, as happens in many feeble, or premature, or excited, or mentally deficient infants, but the reflex is entirely absent. Pressure upon the dorsum of the tongue fails to produce the usual suction response.

I will not elaborate the picture further or describe the attempts which have been made to separate the symptomatology of supratentorial bleeding from that of infratentorial, or deal with the symptoms of localising value by which it is hoped more and more to bring surgical help to our aid. My own experience at this stage is small, so small that you may wonder that I should adduce it. Still, small as it is it serves to illustrate the first of the reasons upon which I believe the uncertainty of our knowledge depends. The obstetrician deals only with the beginning, the neurologist only with the end. For the intervening period we must rely upon the general practitioner and the pædiatrician. I find that I have been asked to see in all eight infants who I thought were suffering from intracranial hæmorrhage. All of these infants died. All showed more or less completely the symptoms I have just described. In three I was able to verify the diagnosis post mortem. The other five were seen in private practice and no post mortem was obtainable. Now it is my experience, and I do not suppose that I am singular in this, that when I am called to see a new-born infant, it is generally because its condition has aroused the fear, if not the expectation, of immediate death. All of these infants were moribund. That there are others suffering similarly but less severely I cannot doubt. Their condition may not arouse the fear of immediate death, although there may be a vague anxiety felt. The mother may be made aware that the doctor or nurse does not think highly of the chance of ultimate survival, but no routine examination is made and the child's recovery is put to the test of time.

---

[1] A contribution to a discussion held at the Medical Society of London on Dec. 10th, 1923.

[2] THE LANCET, 1923, ii., 1129.

Skilled Routine Examination.

The need for a skilled routine examination of the new-born to detect evidence of the presence of intracranial hæmorrhage in any infant whose well-being is in the least in doubt appears to me to be the first and most important deduction to be made from the work which Mr. Eardley Holland has put before us. The certainty with which in general practice the minor degrees of such conditions as pyloric stenosis or scurvy are recognised to-day, and the rarity with which they were detected save in their most pronounced form 20 years ago, suggests the possibility that the attention of the profession has only to be aroused to bring to light many cases of slighter intracranial hæmorrhage. Further, it seems to me to follow that since intracranial hæmorrhage occurs especially in the premature and feeble child we must be careful in adducing the degree of prematurity or feebleness as itself a sufficient explanation of the failure to suck, or of asphyxia or of somnolence. Mere unripeness is in common experience compatible with a high degree of vitality. Death from prematurity or congenital feebleness may be due as often to trauma as to deficient development.

Lastly, in tracing back the history of those cases which we believe to be examples of Little's group of diplegia, it seems to me that it becomes of importance, now that we know the symptoms of intracranial hæmorrhage occurring at birth with some accuracy, to inquire specifically as to the presence of these symptoms. I see little that is to influence our judgment from inquiry as to the nature of the labour. We know that many are born after a difficult and protracted labour, that many are born after precipitate labour, and that many are born after a labour that is in no way abnormal. But a history of constant screaming or of stupor, of aphonia, of refusal to suck, of rigidity, of convulsions, of asphyxia, of facial or oculo-motor paresis or twitching seems to me to have more definite significance. It is clear that after a long interval symptoms which were not specially searched for at the time and which were since the infant survived of slight degree will often be forgotten. Of 63 cases which seemed to me to be examples of Little's syndrome the mother had retained a recollection of asphyxia in 27, of constant screaming in 7, stupor in 4, of aphonia in 3, of refusal to suck in 8. In many there had been anxiety as to survival for the first few days of life. These figures are suggestive. Nevertheless, the difficulties arising from the want of examination of the newly-born in general render such inquiries barren and uncertain.

A Typical Example.

To illustrate this let me recount the case of T. S., an example of the condition I believe to be typical of the after-effects of intracranial hæmorrhage at birth. He came under my care when 12 months old because his mother was distressed by his failure to grasp and to stand. He could sit up only with difficulty. When held upright he made attempts as though to walk, but the legs were then rigidly extended and the adductor spasm was extreme. The hands were stiff and clumsy. He could not pick up anything, but he had learned stiffly and incoördinately to bring his two hands into apposition and he took great and obvious delight in this manœuvre. This represents a stage which the normal child will often reach in the fifth month. The face was stiff, the smile reflex like that of a young infant, and he was a great dribbler. But what struck me most about him was the shape of the head. I do not know the mechanism or the precise significance, but a certain proportion of these babies in early infancy have a strikingly asymmetrical head. Extreme overlapping of one parietal bone over the other has often been noted at birth as indicative of intracranial hæmatoma or extensive tentorial tear resulting in undue mobility of brain. Seen later these children have heads which recall the shape of the Bass Rock. I have here a plaster cast of this child's head taken at a year old. At the present time the child is 2 years old and has made great progress. The head asymmetry is hardly noticeable. He can walk, though with the usual stiffness and rigidity, for a few steps. He still prefers to hold on to the furniture. The hands are still stiff and expressionless. He is bright and intelligent, says a few baby words, and is constantly practising consonant sounds.

Now this child, among the most typical of my cases, happened to be born in a hospital in London, and a few days ago, for the purpose of this discussion, I wrote and asked for two kinds of information. I asked for particulars of the labour and I asked for particulars of the child's condition during the first fortnight. Of the first I received, as I knew I should, the most detailed evidence; of the second, as I feared I should, little of value. The labour was conducted under morphine and hyoscine. In all four doses of hyoscine were given. The conjugate diameter of the mother's pelvis was contracted to four inches. The times of the various stages of labour were recorded with a note upon the condition of the pulse and of the urine passed during labour, &c. One gets the evidence of watchful and skilful conduct and control. But the notes on the child are unsatisfactory. It was born in a condition of blue asphyxia. The caput was very large and was "red and congested in appearance." The posterior parietal bone was depressed below the other. The child weighed 8 lb. 4 oz. Three days later its weight had fallen to 7 lb. 9 oz.

Now, although this child presented one of the classical signs of tentorial tear, no notes of its condition are hereafter available except for some statements as to the colour of its stool. In studying infants observations upon the colour of their stools are too apt to be proffered as a substitute for a routine physical examination. The mother of this child, which left the hospital on the twelfth day, brought the infant back on several occasions complaining of the ceaseless crying and absolute sleeplessness, which she connected in some way with the peculiar shape of the head. She was, however, always reassured. It is the study of cases such as this which makes it impossible for me to discard the belief that Little was right in his contention. I quote it because it shows well the difficulties at present of gaining information as to the state of the child at, or shortly after, birth. An examination of the cerebrospinal fluid or with the ophthalmoscope would have afforded the crucial test.

The Latent Period Following on Recovery from the Immediate Symptoms.

The first of the difficulties, then, with which one has to contend, is the want of systematic examination of the new-born which makes it difficult to detect the occurrence of a hæmorrhage which, while compatible with life, may yet give rise to after-effects. The second difficulty is the long latent period which ensues before these after-effects are commonly appreciated. A consideration of the order in which the different parts of the brain are developed explains the length of the interval which must elapse between birth and the time when the child is taken to a doctor and complaint is made of failure to sit, to stand, to grasp, or to speak. Physiologically the brain of the new-born is active only in part. It is composed almost entirely of grey matter. The medullation of the nerve processes of the cells has not yet been accomplished. Only those processes are medullated which are of immediate and vital importance to the newly-born and which are necessary for the functions of respiration, suction, and circulation. On the other hand, the paths which render possible complicated and controlled motor action and equipoise of the body are not developed. It is the single task of the human infant during the first year of life to develop that marvellous precision and control of complex movement, and to refine more and more those tactile, muscular, and stereognostic senses which are given to man as they are given to no other creature, and to which he owes his survival and supremacy. In the success which attends the infant's strivings we find the earliest indications of his intellectual quality. Darwin's infant steadied his bottle with his right hand at the third month. Others in no way mentally defective are yet less quick to learn. The variation within the normal are great. Unless observation in the home is unusually skilled it may well be that a year or more has elapsed before the backwardness is appreciated. Examination may then show clear evidence of the delay in the assumption by the cortex of control over the voluntary movements. The spastic incoördinate movements may be those characteristic of the normal development at a much younger age. Only when the hæmorrhage has affected those vital medullary reflexes which are active from the first is the child brought sooner. In every instance in which I believe I have been able to recognise cerebral diplegia in the early months of life the child was brought not for spasticity of limbs, but for clumsiness or inability to suck, for aphonia, or for respiratory difficulties, such as stertor and dyspnœa. Such cases are not common and it is clear that apart from the high mortality which is likely to be the immediate result of medullary damage, their survival even to the end of the period of infancy is doubtful. In cases of Little's syndrome without evidence of medullary damage apprehension is often not felt until the beginning of the second year.

The Ultimate Effect upon the Child.

The name Little's disease is only properly applied to two groups of cases and to two only: first, to cases of paraplegic rigidity without mental defect and without convulsions, and secondly, and perhaps more strictly, to cases of general rigidity, usually without convulsions and without mental symptoms or with only that degree of backwardness which is accounted for by delay in that process of auto-education which proceeds by grasp and touch in every child.

Of the first group the paraplegic, which is by no means small and which especially appears to follow premature birth, it may be said at once that no question of mental defect arises. Walking is delayed and for a time their gait is spastic and defective, but of their ability there is commonly no doubt. Their treatment is generally orthopædic. I have elsewhere discussed the question as to whether or not Lord Byron's lameness was so caused. In more than one such case I think close observation in early infancy has shown me that the development of the hand movements was also slightly delayed. It is, however, only when the hand is rendered stiff, and immobile, and anæsthetic that an appreciable delay in the mental development of the child results. As Madame Montessori has so clearly shown, the chief part of infantile education proceeds by the development of the sensori motor paths. In all its efforts the infant must recapitulate the story of its race and gain control over the wonderful instrument, the human hand. In this process of auto-education the diplegic infant, with an antenna relatively immobile and insensitive, lags far behind the normal child. When in addition the face is stiff and immobile, when speech is long impossible, when the laugh and the cry are expressionless and not charged with emotion the simulation of gross idiocy or imbecility is close. Yet the children are not idiotic. Their backwardness is due to sense deprivation. In a sense their defect is the opposite of that encountered in children who are both blind and deaf. Their visual and auditory memories are good. Every avenue to the brain which was closed to Helen Keller or to Laura Bridgemann is open to them, but the single path by which so great a mental development was achieved in their case, that of touch, is here gravely obstructed. A close observation of these diplegic children will often afford convincing proof of the activity of the brain in spite of the expressionless face and immobile, helpless limbs. One of my little patients at the age of 3 could not speak, but he could hum tunes, and he made use of his gift of song to make his wants felt. Thus when he wanted his toy soldiers he hummed the tune of "Onward Christian Soldiers." He now often speaks of what happened to him "before I could talk." In early childhood his parents were told by several medical men that he was seriously mentally defective and would always remain so. He is now a schoolboy of more than average intelligence, gifted especially in mathematics, stiff and a little tremulous in his movements, a villainous writer, fond of games but very bad at them.

Degree of Mental Deficiency.

It is in general only in early childhood that the fears of gross mental defect are aroused. Later after a varying delay the cortical control over the voluntary movements is established more of less effectively and rapid progress is achieved, while education by means of ear and eye proceeds unchecked. In a few cases with microcephaly or with convulsions permanent immobility remains, but even in the worst the intelligence is always much greater than would appear from a cursory examination. In many the ultimate result compared with the initial backwardness in achieving voluntary control of movement is surprisingly good. Memory, artistic perception, æsthetic sense, imagination, and character may all be on a high plane. At the worst the personality is not debased as in primary mental defect. After all the idiot is known by what it does, these children only by what they cannot do. In general they have the saving grace that they try. The actions of the idiot are apt to be purposeless and inconclusive, the child with diplegia from birth trauma struggles and overcomes. Now I may be wrong, but I think that the material upon which most post-mortem neurological investigations have been made does not include such cases. Children so affected are seldom to be found among the inmates of institutions for mentally deficient children. They are to be found in the homes of the people, a little stiff and awkward in their movements, sensitive, retiring, self-conscious, a little odd to look at, and peculiar in temper. Most of the older children who have been brought to me have been under treatment by an orthopædic surgeon; few of them have been taken for advice as to their mental condition. It is characteristic, I think, that the name by which we know the condition commemorates the founder of the Orthopædic Hospital. Their gait may be faulty, those who know them well are in no doubt as to the acuteness of their reasoning powers. I suggest that the neurological studies of which I spoke and which are held to prove the negligible part which trauma at birth plays in the causation of cerebral diplegia are concerned with material derived from very different sources.

The use of the term Little's disease has been extended unjustifiably to include all cases of diplegia, and in the past attempts have been made to trace the origin of gross mental deficiency with spasticity and epilepsy to intra-natal trauma. The failure of all such attempts must not deter us from the endeavour to trace far more clearly than is possible at present the after-history of infants who suffer intracranial hæmorrhage at birth and survive.

That this accident does not always produce permanent damage is certain. Cases in which hæmorrhage occurred have been followed for many years, and the children have thrived normally. That other types of disturbance may owe their origin to intracranial hæmorrhage is possible. That this particular type in which the sensori-motor defect is the only defect, or the predominant defect, does owe its origin to intracranial hæmorrhage seems to me certain.

Another Case.

I show as a typical example of extreme generalised rigidity from cerebral birth injury a boy aged 16. His birth was very difficult. His doctor tells me it was the most difficult forceps case he ever had. There was bilateral subconjunctival hæmorrhage. He was born asphyxiated and subsequent alarming asphyxial attacks recurred during the first week. He screamed incessantly. He was christened at once, in fear that he would not survive. He has been sent to a school for mentally deficient children. There he has learned very little. He can read about as well as a child of 7. His writing and his figures are almost illegible. What he has learned he has learned from his devoted mother. She is not an intellectual woman, and the intellectual development which I have seen in other boys similarly affected in intellectual homes has not been achieved. But he holds his own in the family life. He is affectionate, honourable, well-behaved, and his father and mother are devoted to him. This scholar from the school for mental defectives plays a first-rate hand of whist and he makes himself very useful in housework of all sorts and in cooking. He can control his stiff, awkward limbs in a wonderful way during certain practised actions. Versatility is not for him. But, like a juggler, by long effort he succeeds.

PELLAGRA IN THE BRITISH ISLANDS.

By A. DOUGLAS BIGLAND, M.D. LIVERP.,
M.R.C.P. LOND.,
HONORARY PHYSICIAN, DAVID LEWIS NORTHERN HOSPITAL,
LIVERPOOL; LECTURER IN CLINICAL MEDICINE,
UNIVERSITY OF LIVERPOOL.

THE rarity of pellagra in this country is not surprising considering the conditions which appear to favour its onset, but the disease is endemic in England, and isolated cases are noted from time to time. That more cases are not recorded must in part be due to the difficulty of diagnosis and to the superficial resemblance of this condition to other well-known physiological and pathological states. Even during epidemics of pellagra in other countries many cases would be overlooked were it not for the presence of so many typical cases at the same time; hence the problem for the medical man who has never seen a case before is much more difficult. A study of the literature suggests that many cases occur without being diagnosed. In 1913 great interest was taken in the disease, and many medical men in England reported cases in the more widely read journals. Before and since that date the records reveal merely isolated instances of the condition, and it is practically certain that in 1913 there were many cases simply because they were looked for and that the falling-off in the numbers since corresponds to the failing interest of medical practitioners. It is hoped that a brief summary of the cases occurring in this country may do something to re-awaken that interest without which, even in typical cases, a diagnosis is almost impossible.

In October, 1912—just 11 years ago—Sambon and Chalmers,[1] writing under the same title as the present, described the first cases in this country. It appears that Billod,[2] in 1860, received a letter from the Inspector-General of the Scottish Lunatic Asylums to the effect that he had seen two idiot brothers in an asylum in the east of Scotland, both showing manifestations of pellagra. These constitute the first cases in our literature. In 1866 Howden[3] described the disease in a woman in the Montrose Royal Asylum. No further cases are noted until 1906, when Cassels Brown[4] published a case in Rock Ferry, Cheshire. (From careful consideration of the appearances described I do not think that this was true pellagra.) The next record is in 1909, when Dods Brown and Cranston Low[5] diagnosed a typical female pellagrin in the Royal Edinburgh Asylum. So many cases, relatively, having appeared in Scotland it seemed to Sambon and Chalmers[1] that a trip to this part of the country might reveal yet more cases. Accordingly, in 1912, these workers proceeded north and, as had been anticipated, several more pellagrins were diagnosed.

The publication by Box[6] in 1913 of his two cases in brothers living in Slough seems to have stirred up the greatest interest in the disease, and this, together with the work of Sambon, gave rise to a flood, relatively speaking, of new cases. These can be best presented in tabular form.

TABLE I.—*Pellagra Cases in the British Islands in 1913.*

Author.	Locality.	No. of cases. M, male; F., female.
Box.[6]	Slough.	2 brothers.
Hammond.[7]	Isle of Wight.*	1 F.
Sambon.[8 9 10]	Lymington (New Forest).	1 M.
	Slough.	1 M.†
	Shropshire.	1 F., aged 7.
	Cardiganshire.	1 F., aged 63.
	Napsbury County Asylum.	1 F. (young).
	Prestwich County Asylum.	1 F., aged 17.
	Walthamstow.	1 F., aged 45.
Cole.[12]	Bethnal House Asylum.	1 F.
Lempriere.[13]	Llanidloes (Glamorgan).	1 F.
Reid and Calwell.[14]	Belfast.	1 M.
Johnstone.[15]	Holloway Sanatorium.	1 F.
Rainsford.[16]	Stewart Institution (Co. Dublin).	1 F.
Spurgin.[17]	London.	1 M.‡

* Probably began in Banffshire.
† A third brother of Box's two cases.
‡ Probably pityriasis rubra.

In the same year (1913) Blandy [11] quotes 11 other cases in the Middlesex County Hospital at Napsbury, one of which had already been described by Sambon.[10] Of these all but one were females. In 1914 only four cases were described. Willcocks[18] mentions a female case living in Waterloo-road, S.E.; Box[19] described a child suffering from pellagra at St. Thomas's Hospital; Little[20] had a case, a male, in St. Mary's Hospital, London, and Ross [21] described a female pellagrin in the Royal Edinburgh Mental Hospital, where a similar case had occurred in 1909. With the coming of the great war interest in pellagra of necessity began to wane, so that in 1915 only two cases are reported, one by Little[22] of a doubtful case in a boy living in Poplar, and a female in Glasgow Royal Mental Hospital, described by Henderson.[23]

A gap in the literature now occurs; not till 1920 was the next case, a female living in Edinburgh, reported by Wood.[24] In 1921 Galbraith [25] published a male case in Glasgow, and in 1922 the author [26] mentions a case in a lady living outside Liverpool. Quite recently Hutchison and Paterson[27] have reported two cases in female children occurring in Great Ormond-street Hospital.

It is clear, therefore, from the above review of the literature that pellagra is endemic in the British Islands. Sight must, however, not be lost of the fact that the disease may become epidemic, especially in asylums. In the Middlesex County Asylum, as already stated, 11 cases occurred in the year 1913, and at the Lancashire County Mental Hospital, Rainhill,[28] during 1922 14 new cases were diagnosed.

Table II. represents mental hospital mortality figures for pellagra in England and Wales for from 1913 to 1922 inclusive, and is of interest in its bearing upon the mortality of the disease in general.

TABLE II.[29]

Year.	M.	F.	Total.	Year.	M.	F.	Total.
1913 ..	0	8	8	1919 ..	0	0	0
1914 ..	0	1	1	1920 ..	0	2	2
1915 ..	3	12	15	1921 ..	0	1	1
1916 ..	2	6	8	1922 ..	3	15	18
1917 ..	0	9	9				
1918 ..	1	3	4	Total .	9	57	66*

* Of these 66 deaths 86·4 per cent. were in women.

Most of the cases were in Lancashire, many of them in one mental hospital. Cases also occurred in the East Riding of Yorkshire, Norfolk, Hertfordshire, Monmouth, and London.

From consideration of the preceding figures it will be seen that the Liverpool district is especially an endemic focus of pellagra, since this is the area mostly concerned in supplying cases to the mental hospital at Rainhill; in some instances these cases are pellagrous before admission. It is surprising that more cases of the disease are not noted in this district. The publishing of the following notes of a new case in Liverpool may, perhaps, stimulate local interest in the disease.

A male, aged 59, a painter now out of work, was sent to me by Dr. Edmund Hughes, of Liverpool, in June, 1923, as a possible case of pellagra.

History.—About March, 1923, patient began to be ill, giddiness being the first symptom noticed. In April his memory began to fail and he became mentally confused. Very shortly after this the backs of the hands became red and burning, and this was followed by a brown coloration. He volunteered the statement that he had suffered from diarrhœa, which lasted a few weeks. There had been no soreness of the tongue and no pain in the back; appetite had been good and he thought he had not lost weight. He had had no previous attacks of a similar nature and had seen nobody with hands like his. Apparently he had never lived abroad. His diet he described as follows: Breakfast: An egg beaten up in tea, salt fish, bread and butter. Dinner: Hot pot, or something like it. Tea at 7 o'clock: Fish, bread and butter, and tea. Supper: Bread and cheese.

On further inquiry it was elicited that the man lived all alone in rooms and that he had to prepare his own meals. He admitted that he probably went without any food at all on many occasions. The fact, too, that the man is out of work suggests that the diet was in reality inadequate.

Condition on Admission.—On the 26th, when admitted to the David Lewis Northern Hospital under my care, he appeared to be prematurely aged and very confused, with very deficient memory. Typical symmetrical pellagrous erythema with pigmentation on the dorsum of both hands, the skin was swollen, dry, and scaly. No signs of dermatitis in other areas. Tongue normal; pupils equal, reacting to light and accommodation; knee-jerks exaggerated but equal; no clonus and no Babinski. Other systems revealed nothing of note. There was no diarrhœa during the man's stay in hospital.

Laboratory Investigations.—Blood-sugar, 0·08 per cent.; blood-urea, 12 mg. per 100 c.cm. Fractional test-meal revealed complete absence of HCl in all samples. Fæces and urine showed nothing abnormal. Wassermann reaction completely negative; spinal fluid gave only a luetic zone curve with the gold sol test (1233211000).

Treatment.—The treatment given was practically entirely dietetic. A liberal mixed diet was ordered, to which were added six eggs per diem. With these simple measures the dermatitis on the hands soon cleared up by desquamation and pealing, leaving a smooth pale skin surface. The patient's general condition improved and his mind became decidedly less confused. Notwithstanding the vigorous feeding a gain in weight of only half a pound was recorded. The patient was discharged from hospital on July 30th, 1923.

It would appear that the ætiology in this case was intimately associated with poor feeding, and that simple correction of this error brought about rapid amelioration of the symptoms for the time being. Whether next spring will show a recrudescence of the condition probably will depend upon the man's diet during the coming winter.

In conclusion, I think that particular note should be taken of the colloidal gold test on the spinal fluid in pellagra cases. Four cases have been examined in this respect; three of these fluids were sent from the County Mental Hospital, Rainhill, by the kindness of Dr. G. A. Watson, and the fourth is from the present case. One case gave the serological findings of a typical general paralysis, which was in accord with the clinical findings. The other three had fluids perfectly normal in every respect except that the colloidal gold test gave a luetic zone curve in each. This finding, in the absence of disseminated sclerosis, may be of value as a diagnostic feature in pellagra.

LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—The annual dinner was held at the Savoy Hotel, London, on Dec. 6th, Sir Alan Anderson presiding. Over 300 past and present students were present, and the guests included, among others, Lord Riddell, Lady Rhondda, Sir Humphry Rolleston, Sir Walter Schröder, Miss Elizabeth Robins, Mr. V. Warren Low, and Mr. Ernest Miles. After the loyal toasts, the chairman proposed the School and Hospital. He chronicled with sorrow the death of Dr. Percy Saunders and the approaching retirement from the department of pharmacology of Dr. Fred Ransom, and then discussed in a hopeful spirit the present position and the future of the institutions to which both of these men had given valued service. At the present time neither the school nor the hospital were paying their way. The hospital was in the same difficulties as all other metropolitan hospitals, but steps were being taken to enable it to meet its charitable obligations. As to the school, it was a volatile body which had recovered from bad times after the Boer War, when the entry sank to 13, and would doubtless recover again, though this year's entry of 36 was less than half that of a few years ago, when its buildings had been greatly enlarged to meet the demand for more space. The hospital was unique among teaching hospitals in that appointments on the honorary staff were available for women graduates. Nine beds had been endowed during the last year, and £16,500 had been received for the extension of the hospital, largely through the efforts of Dr. May Thorne, the honorary appeal secretary. The school had an excellent academic and athletic record for the past year. Mr. J. Cunning proposed the Guests in appropriate terms of greeting, and Prof. W. E. Dixon, F.R.S., replied on their behalf in a tone of pleasant banter, accounting for the existence of a women's movement in a delightful exposition of the time-honoured argument that life was now organised "from incubator to incinerator" outside the home. Prof. Louise McIlroy, toasting the Chairman, spoke of the illustrious family to which Sir Alan Anderson belonged, and pictured him as a very perfect knight, ever championing the cause of women.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

THE COMPARATIVE VALUE OF COCAINE SUBSTITUTES.

AT a meeting held on Dec. 7th a discussion took place on this subject. The meeting was arranged by the Section of Laryngology, Dr. H. J. BANKS-DAVIS presiding, and the Sections of Anæsthetics, Odontology, and Otology participated.

Dr. P. WATSON-WILLIAMS (Bristol) said that cocaine was discovered in 1860, and was first used by Keller in 1884 in ophthalmic practice, being thereafter widely used as a surface anæsthetic, and during a long period for injection anæsthesia. Though cocaine had been proved to be valuable in many aspects of medical practice, its toxicity and its abuse by the narco-maniac created a demand for substitutes, as evidenced by the American Committee for the study of toxic effects of local anæsthetics, and the Special Committee of the Ministry of Health. Some of the substitutes now procurable were of great value, and in a measure—i.e., for infiltration anæsthesia and nerve-blocking—had largely displaced cocaine. The repute of most of them, however, was but ephemeral. The ideal local anæsthetic should possess anæsthetic efficiency and lack toxicity in clinical dosage. It should also be capable of sterilisation, readily soluble, non-irritating, and devoid of temptation to the narco-maniac. He asked whether there was yet sufficient evidence that any cocaine substitute was free from the addiction danger; certainly most of the substitutes were highly selective for the cortical centres, and some could cause cerebral excitation. He thought the risk of addiction to cocaine on the part of patients had been exaggerated. The comparative clinical value of cocaine and the other local anæsthetics largely turned on the purpose for which anæsthesia was required; one which was safe for a small operation field might be unsafe for a wider area. Value must be judged according to its employment by (*a*) surface absorption, (*b*) infiltration or nerve-blocking, (*c*) by intra-spinal block. Probably a stronger anæsthetic was required for the nasal mucosa than for the urethra or conjunctiva. Also there might be greater risks in the fauces and tonsils than from the same dosage of the same anæsthetic in the nasal passages.

The Laryngological Standpoint.

Dr. Watson-Williams then proceeded to speak specially of surface anæsthesia in laryngological practice. His experience of eucaine and butyn was limited to their use by surface absorption, and of this alone he spoke. Eucaine he had used since 1902, and later the more soluble eucaine lactate in a 5 to 12 per cent. aqueous solution for rhinological cases. It was fairly efficient for the galvano-cautery, but as it did not produce mucosal ischæmia, adrenalin generally needed to be added. Butyn he had used for nasal anæsthesia in 2 to 5 per cent. aqueous solution. Its action appeared to be exactly similar to that of eucaine lactate, but it was two or three times as strong in the matter of anæsthesia and at least three times as toxic. In the case of all the known substitutes, adrenalin required to be added when vascular constriction was needed. The adrenalin, however, was often followed by a somewhat prolonged secondary turgescence, sometimes by irritation, and coryza lasting two or three days. For these reasons he now restricted his use of eucaine or butyn to such processes as Eustachian catheterisation. He had often used 5 per cent. butyn for nasal sinus exploration. Butyn was quite as toxic as cocaine and less efficient. He suggested to his son, Mr. Eric Watson-Williams, that he should undertake an experimental research from the clinical standpoint on the toxicity of cocaine and its substitutes, and the result of that had already been published.

Statistics of Toxicity.

Dr. A. E. Bulson (Jackson, Mich.) had described his clinical experience of butyn as a surface anæsthetic, and stated his belief that the combination with epinephrin provided a more profound anæsthesia than did butyn alone, and decreased the chances of toxic effects of butyn. Bulson advised a 2 per cent. butyn solution for light anæsthesia, and for major operations a 5 per cent. solution combined with epinephrin was used by first swabbing the operative field, and within two or three minutes applying to the area, and, if possible, over the source of the sensory nerve supply, pledgets of cottonwool soaked with the solution, but with the surplus squeezed out. About ten minutes later he found the patient, in practically all cases, suffered neither pain nor discomfort. Dr. J. F. Biehn (Chicago had furnished to Mr. Eric Watson-Williams notes of five fatal cases from butyn, and recommended that for topical application to the nose the solution of butyn should not exceed 1 per cent. Butyn, like cocaine, novocaine, stovaine in lethal doses caused convulsions and death from respiratory paralysis. Emil Mayer had collected reports to date of 42 deaths following the use of local anasthetics occurring within the last three years—viz., 18 from cocaine, 10 from novocaine and cocaine, 4 from butyn, 4 from apothesin, 3 from procaine and novocaine, and 1 each from stovaine, alypin, and butyn with cocaine. As the substitutes were used far less frequently than cocaine, none of them could be called safe. In relieving the pain of tuberculous ulceration Dr. Watson-Williams had found orthoform and anæsthesin valuable.

In using cocaine it was very important to guard against any being swallowed. For 25 years he had employed, for light anæsthesia and for routine examination, 20 per cent. solutions, spraying 5 to 10 minims without adrenalin, and only very rarely had patients displayed any symptoms of distress due to cocaine. He could only recall three cases of serious faintness following strong cocaine applications; never had he met with a case which seemed to contract the habit. Two important adjuvants lessened the risks attending the use of cocaine in surface anæsthesia —namely, (1) the preliminary or simultaneous use of adrenalin; (2) as De Havilland Hall pointed out in 1888, the addition of a trace of sodium bicarbonate immediately before applying greatly increased the anæsthetising potency of a given strength of cocaine solution. Seeing how general was the use of cocaine in medical work, there were very few cases of either death or narcomania from its employment. Some fatalities were certainly falsely attributed.

The Ophthalmological Standpoint.

Mr. R. FOSTER MOORE said the most important drugs which had been used for local anæsthesia were the following: holocaine, α and β eucaine, euphthalmine, novocaine, anæsthesin, subcutin, antinesin, alypin, stovaine, tropacocaine, butyn. An important question was that of drug addiction, and it would be of value to hear of any cases of this following on the use of local anæsthesia for surgery or as a result of prescriptions. If, without the penalties attaching to cocaine, there were not cases of abuse of the substitutes, that would have weight in favour of the substitutes not being regarded as addictable drugs. For ophthalmic work was there a drug or combination of drugs which was equal or superior to cocaine on the following points? (*a*) degree and rapidity of anæsthesia; (*b*) amount of irritation caused, remembering that some might get into the eye during an operation and cause iritis; (*c*) liability to cause desquamation or corneal epithelium; (*d*) degree of absorption if injection of eye not quite absent; (*e*) toxicity; (*f*) stability and sterilisability by boiling; (*g*) whether it stimulates the sympathetic nerve; (*h*) its liability to become a drug of addiction. He said the chief uses of local anæsthetics in ophthalmic work included instillation anæsthesia, for tonometric examinations, for removal of foreign bodies from conjunctival sac or cornea, cauterisation of the cornea, syringing lacrymal ducts, and indeed all operations on uninflamed eyes, unless the patient was so young as to render a general anæsthetic desirable. For the last group of intra-ocular operations he believed there were a number of cocaine substitutes which were sufficiently efficacious for surface anæsthesia. For infiltration anæsthesia he thought novocaine in 1 or 2 per cent. solution was so efficient and so little toxic that cocaine did not enter into competition with it. Cocaine hydrochlorate was used in solid form for topical application in incising meibomian cysts and in muscle operations, and it would be important to ascertain whether novocaine injections were not equally satisfactory for these purposes. An important quality of cocaine was its power of stimulating sympathetic nerve, producing dilatation of the pupil, and widening of the palpebral fissure; it would be an advantage to know how far other drugs had this effect. He had found holocaine in 2 per cent. solution satisfactory for superficial anæsthesia by instillation, but it caused more smarting than a like strength of cocaine. He had not used it for intra-ocular operations; 2 to 4 per cent. stovaine he regarded as unsatisfactory for cataracts; on two occasions he had had to complete the operation with the aid of cocaine.

The Dental Standpoint.

Mr. F. N. Doubleday spoke from the dental standpoint. He said the British Dental Association recently issued a circular letter to all members asking whether they regarded the use of cocaine as indispensable in their practice. Of 2327 who replied, 1912 said Yes; 410 said No; the other answers were indefinite. He numbered himself with the 410, as he found novocaine, injected hypodermically, produced as rapid an onset of anæsthesia and as profound a loss of sensation as cocaine. As the result of a good deal of testing he firmly believed that novocaine was the most efficient cocaine substitute—i.e., 0·02 g. of novocaine and 0·0005 g. adrenalin. He gave three examples of what this novocaine solution would do. A single injection of 1 c.cm. into the vicinity of the nerve entering the apical foramen of a tooth would, within one minute, so anæsthetise a live sensitive tooth-pulp that it could be painlessly removed; 50 mils injected into the soft tissues on either side of the alveolar process would, within a minute, permit the removal of a tooth, except a mandibular molar, without discomfort; 2 or 3 c.cm. injected into the neighbourhood of the inferior alveolar nerve would produce complete hemianæsthesia of the mandible and allow painless removal of any mandibular tooth of that side. This anæsthesia took from 5 to 30 minutes to develop, according to the skill with which the solution was placed in the region of the inferior dental foramen, and he had done long operations, involving the use of hammer, chisel, and electric engine, with novocaine, and the patients still remained his friends! Most of the other cocaine substances he had named yielded similar results in operations, though with less certainty and with more marked after-effects. He had used novocaine in his hospital practice for 16 years without serious ill-effects, even though the physical condition of many of the patients was poor.

Seen by the General Anæsthetist.

Dr. J. Blomfield, speaking as an anæsthetist, said the use of these drugs in his clinic was confined to injection; he had not employed them for surface anæsthesia. He had entirely abandoned the use of cocaine, and he believed most of his colleagues had also. The drug now almost entirely used for local injection was novocaine, in a 2 per cent. solution. Large amounts of novocaine could apparently be injected without untoward symptoms occurring. That was especially the case when it was injected into the sacral canal. Still, when large amounts were given in this way an alarming series of symptoms were likely to happen, though no fatality from them had yet been recorded—namely, generalised convulsions, affecting nearly all muscles. One such case he saw appeared to be going through a severe epileptic fit. The drug he chose when spinal injections were needed was stovaine. In some of the alleged fatalities from it the drug could not justly be accused of the disasters when all the circumstances were taken into account. However, stovaine was now much less frequently a cause of bad symptoms now it had been found that its chief danger lay in the production of a fall of blood pressure. This could be counteracted by having the patient in the head-down position.

The Otological Standpoint.

Sir William Milligan, speaking as an otologist, said that in view of the ground which had already been covered by previous speakers, he proposed to practically limit his remarks to butyn. Otological work did not permit of the same range of utility for the employment of local anæsthetics as did that of laryngology, rhinology, ophthalmology, and dentistry. This was largely because of the configuration, position, and remote accessibility of the organ. So far, cocaine had practically held the field. Any new anæsthetic must be critically examined from several points of view: (1) Was it as effective as those now in use? (2) Was it reliable? (3) Had it toxic properties, and if so, how did it compare with other local anæsthetics? Butyn could be applied directly to the tissues in either the fluid or the solid form, by subcutaneous injection, or by means of infiltration. In aural work it must be in close contact with the mucosa of the middle-ear cleft; this was accomplished by either swabbing or the local application of small pads of non-absorbent wool soaked in a watery solution of the drug. Thus its use was largely confined to the cases of middle-ear disease in which the tympanic mucosa was exposed. Instilled into the meatus as a preliminary to the removal of polypi or granulation tissue it was as satisfactory as cocaine. Applied to the mucosa of the middle ear or Eustachian tube orifice it produced anæsthesia in from one to two minutes, but not of sufficient degree for the application of a strong caustic. A 1, 2, or 5 per cent. watery solution used every three minutes until four applications had been given caused a more profound anæsthesia, which lasted half an hour. That the drug had no ischæmic effect was not such a disadvantage in aural as in other work, and this defect could be made good by adrenalin. As to any toxic properties of butyn, no patient of his had been in any way inconvenienced by its employment. In any very painful proceeding, such as incision of the drum head, the butyn dissolved in aniline oil enhanced its anæsthetising power. For the production of infiltration anæsthesia a 0·5 per cent. solution gave quite satisfactory results, as the effect was deep and lasting. In aural work butyn did not appear to him to offer any particular advantages in comparison with cocaine; on the other hand, it had certain disadvantages, one of which was its failure to cause contraction of the tissues of an organ like the ear, where there was very little room to work in. Another drawback was the hyperæmia it produced. The advantages he had found from butyn were as follows: Its action was more rapid, more powerful, and of longer duration than that of cocaine, its potency being twice that of the latter. It was not damaged by keeping or by boiling, and it did not engender a "habit"; moreover, it could be used effectively in lower concentrations than could other synthetic anæsthetics. Two of his patients contracted the cocaine habit. In the net result his preference was for cocaine.

Experience with Butyn.

Mr. Eric Watson-Williams (Bristol) confined his remarks to butyn, of which much was being heard at the present time. By the courtesy of Dr. Biehne, of Chicago, representing the proprietors of this substance, he had received important information concerning it. This anæsthetic was selected after numerous trials and experiments with analogues, and since it was put on the market in 1921 there had been a modification of view in regard to its degree of toxicity. Animals with relatively small brains tolerated much larger doses of cocaine than did those with larger brains, and the latter survived larger doses than did man.

Earlier in the trial it had been suggested that in man butyn was less toxic than cocaine, but further experiments on monkeys showed that this view could not be upheld; butyn must be regarded as at least—gramme for gramme—as toxic as cocaine. Bulson advised a 5 per cent. application of butyn for the nose, but that recommendation had since been modified. Mr. Eric Watson-Williams then read, from Dr. Biehn's letter, details of five deaths which had followed the use of butyn. The first was that of a woman aged 35, who had a goitre, and who came for nasal septal resection. She was given morphine 1/6, atropine 1/200 hypodermically. Cocaine was sprayed in the nose, followed by 5 per cent. butyn on tampons. Death, with convulsions, occurred in ten minutes. There was no post-mortem examination. The second was that of a boy aged 16, who came for the same operation, and the anæsthetics were the same, except that the cocaine sprayed was of 1 per cent. strength. He died in 20 minutes, and status lymphaticus was diagnosed. The third was a woman aged 38, who came for removal of tonsils. Morphine 1/8 was given half an hour before operation, and 4 per cent. cocaine was applied on a tampon to the pillars of the fauces and the base of the tongue. Then 2 drachms of 1/4 per cent. butyn was injected into the right tonsil. The left tonsil was similarly treated. Before the operation could be started the patient fainted, then had convulsions, and attempts at resuscitation failed. Death was attributed to paralysis of the respiratory and circulatory centres. The next case, of a man aged 26, came for tonsillectomy. The tonsil was injected with an unknown quantity of butyn solution, prepared by adding 2 drachms of a 5 per cent. solution to 3 oz. of distilled water and 12 drops of epinephrin. After the injection of one tonsil the patient became apprehensive, but was reassured, and then the other tonsil was injected. In a few moments he fainted, passed into convulsions, and died. It was reported as a case from surgical shock; there was no post-mortem. In the last case 40 c.cm. of a 2 per cent. solution was used to produce sacral anæsthesia, and death occurred in ten minutes—obviously a case of overdose. The proprietors stated that they did not recommend butyn solution, particularly when combined with epinephrin, for hypodermic injection in such vascular areas as the tonsil, nor the concentrated solution for the nasal septum. Butyn acted more rapidly than cocaine, was more efficient, and its effects were more prolonged. It should be used in more dilute solutions. Subjects of status lymphaticus showed an idiosyncrasy to butyn. It was reported that butyn had been used in 1 per cent. solution by dentists in over a million cases for extraction without one untoward result. In conclusion, the speaker deprecated drawing conclusions from any but complete case-reports.

Discussion.

Mr. S. F. St. J. Steadman said that in his dental work he usually preferred to inject nerve trunks away from the area of operation rather than doing a submucous infiltration at the actual site of operation; there was then less liability to any complication by sepsis. He had not dared to use cocaine for this, as that drug was decomposed by boiling. He usually employed an isotonic 2 per cent. solution of novocaine, and he was fairly satisfied with this drug, but on one or two occasions it had failed him. He had used a 1 per cent. non-isotonic solution of butyn in 200 cases. In only one did he fail completely to get anæsthesia, and in two the degree was not satisfactory. In the case of the larger trunks of nerves it was usually desirable to wait 15 minutes. The after-pain was much reduced if the Ringer solution was prepared fresh each morning in the manner he detailed. It was not desirable, he found, to use more than 1/600 gr. of adrenalin for each injection or each series. Butyn was responsible for a considerable amount of after-pain, possibly because it was a sulphate and was decomposed by chlorides. A freshly-prepared solution of novocaine gave less after-pain than did nitrous oxide gas.

Dr. William Hill agreed with Dr. Watson-Williams and Sir William Milligan that in competent and experienced hands cocaine was not a dangerous drug. One could test a patient's tolerance by using 2½ per cent. on the nose, and if there were no signs of palpitation of the heart one could safely proceed with it. If such signs did occur, recourse should be had to a general anæsthetic or one of the cocaine substitutes. He remarked that the early reports as to the universal safety of butyn had now been modified as a result of wider experience. He had found butyn an inconvenient drug to use for two reasons: it was not ischæmic, and the necessary addition of adrenalin caused coryza, owing to irritation of one or other turbinal. And sometimes it was uncertain in its action. He seldom had cases of cocaine poisoning. Two other drugs could be used for surface applications: one was eucaine lactate, but the operator was very liable to be "let down" by it. Stovaine was the other; it was soluble in 10 per cent. solution, but only that morning he had a case which proved it was not free from toxic risks.

Dr. Albert A. Gray (Glasgow) spoke of the effect of some of the local anæsthetics on the tympanic membrane. Eucaine with aniline he found very much inferior to cocaine; and the same was true of novocaine and stovaine. And aniline itself had the defect of its virtues; it so easily penetrated epidermis. He had never had a patient who became subject to the cocaine habit; the nearest to that was a man who needed his nose cauterised several times, and he continued to come longer than necessary because of the pleasant after-effects. He (the speaker) never experienced trouble or anxiety in regard to cocaine, perhaps largely because he used it chiefly in the form of an ointment, which did not result in the heart being taken by surprise.

The President related a case in which a man attended often for throat spraying with cocaine, and then met with an accident which prevented the treatment being continued. He then confessed he had kept up his attendances longer than necessary, as he liked the subsequent sensation.

Mr. Woodman spoke of a patient on whom cocaine was first used, and then at a subsequent visit novocaine, and he requested that cocaine be used in future.

Mr. T. B. Layton said the various points in connexion with local anæsthesia struck users in different ways according to their special work. In ophthalmic and rhinological work the important point was the irritative effect of the drug. Sometimes he had injected ½ oz. of 0·5 per cent. novocaine without bad results. He proceeded to speak on the influence on the patient of suggestion. The patient's fear and apprehension were real factors, and they might explain some of the events which had been related in this discussion. And if the doctor was afraid of toxic symptoms when using a new drug, this state of mind was subtly communicated to the patient. Dr. Graham Brown, of Melbourne, would not use novocaine; he always employed cocaine, and was careful to have the same brand as that so largely used by dental surgeons. In the nose local anæsthesia was closely concerned with hæmostasis, and butyn did not cause hæmostasis. He used 1 per cent. novocaine with adrenalin for injecting tonsils. He had put that into one tonsil of a patient, and into his other tonsil 0·5 butyn with four times as much adrenalin as in the other, and the amount of hæmostasis during the operation on the two sides was not to be compared. It was necessary to go on adding adrenalin until the quantity was quite considerable. He believed there was somewhat more danger of reactionary hæmorrhage with local than with general anæsthesia, certainly in the case of the tonsils.

Mr. Mark Hovell said that for some time past he had discontinued using cocaine for nasal work, employing eucaine in its stead when local anæsthesia was required, of 5 per cent. to 10 per cent. strength. To clear the nostril of polypi he used 2 per cent. novocaine.

Dr. J. KERR LOVE said he had used alypin. Some years ago he tried that in 10 per cent. solution for surface application in the nose, and after using it about 20 times he concluded it was much more toxic than was cocaine of the same strength. He therefore gave it up. Before using cocaine he gave the patient a hypodermic injection of hyoscine compound (B. W. & Co. " A ") 20 minutes before the operation, and he had found that was a very safe antidote for symptoms of incipient cocaine poisoning; as also was a 10 per cent. solution of calcium chloride injected intravenously.

Mr. SYDNEY SCOTT said he had found butyn useful for patients who had disagreeable after-symptoms from cocaine. He had never seen or heard of a case of addiction to the cocaine habit following its use for surgical purposes. He had never done a mastoid operation under local anæsthesia, but he had removed a brain abscess under novocaine. The patient was unconscious, and was with difficulty aroused subsequently. There was some reflex action when the cranium was opened, but he was able to find a deep-seated abscess and enucleate it from the parietal region under local anæsthesia with help derived from the fact that the patient was partly comatose. Sometimes the application of a little pure carbolic acid with Condy's fluid to the operation area enabled a patient to tolerate incision of the tympanic membrane. As long as 25 years ago students at St. Bartholomew's Hospital were taught that it was very dangerous to spray the nose with cocaine. The great precaution to observe was against the swallowing of cocaine by the patient, which could be done by having the head leaning forwards. Following novocaine and adrenalin there was some liability to cramp in the heart region, probably due more to the adrenalin than to the novocaine. He had used a 5 per cent. isotonic solution of butyn in the same way as he had used cocaine, chiefly for Eustachian catheterisation, and he could confirm the conclusions recently set out by Dr. William Hill.

Mr. HERBERT TILLEY said he had used novocaine frequently for resection of the nasal septum and for operating on the antrum. It was very efficient and he had never seen the slightest danger from it, nor even uncomfortable symptoms. He had also used it 15 times for urgent tracheotomy in cases in which a general anæsthetic was not only impossible, but would probably precipitate disaster. He had been struck by the comparatively large quantity of novocaine which could be used without any apparent distress. He agreed with those who felt that we did not yet possess a drug which produced the combined qualities of anæsthesia with contraction and retraction of the tissues. And if a drug did not possess ischæmic properties, he did not see how it could take the place of cocaine in ordinary practice. For 15 years he had not seen a case in his consulting room which gave either him or the patient any anxiety. He fully agreed with Mr. Layton's remarks on the influence of suggestion.

Reply.

Dr. P. WATSON-WILLIAMS, in reply, said Mr. Eric Watson-Williams found that cocaine became rapidly changed in the body into ecgonine, the harmless base. His own experience with novocaine had always been happy when used for injection purposes. He thought the profession had got into the wrong mental attitude in regard to cocaine. If a better substance could be found it would be welcomed, but it was a pity to make an attempt to black-list it as something to be avoided if possible because it was socially abused at a time when it was available for anyone. This was the wrong standpoint for scientists. There were those who would like to prohibit the use of alcohol by the profession in the same way.

SECTION OF BALNEOLOGY AND CLIMATOLOGY.

AT a meeting of this section on Nov. 29th, Dr. C. W. BUCKLEY delivered as his Presidential Address an introductory paper to a discussion on the subject of

DIURESIS.

He said that members of the section employed therapeutic remedies which differed in many respects from those in the Pharmacopœia and had not received proper attention from the teachers of pharmacology. The gross effects of mineral-water drinking were obvious, but how and why these effects were produced was often obscure. When mineral waters were employed to produce diuresis, the aim of the physician was to promote the excretion of harmful solids, the result of a disordered metabolism, rather than the mere excretion of water. For this purpose certain mineral waters of low concentration were superior to distilled water; and the effects of the former were often prolonged, while those of the latter passed off rapidly. Marshall and Carr, who had investigated the effect of plain water drinking, concluded that the excretion of chloride and of urea was increased, while creatinin was little affected. The results of these investigations were somewhat vitiated by the fact that no fluid was allowed during the control period, so that the control results were hardly normal, and further by the fact that the degree of hardness of the water drunk was not stated. The latter was a point of some importance, since it was known from the experiments of Keller that hard water possessed a greater diuretic power than distilled or soft water.

The total amount of salts in a dose of mineral water which would produce diuresis was very much less than that required to produce the same effect in artificial solution. Two explanations of this were possible: either the mineral elements in the natural water were more active through existing largely as free ions, or the various ingredients of the water acted as adjuvants to one another, an effect which had been demonstrated by the work of Schloessor in the case of certain salts as adjuvants to caffein. The action of mineral waters in producing diuresis was shown by Blum to be partly upon the cells of the tissues generally and partly upon the renal epithelium. Blum therefore classified certain salts, notably the chlorides of calcium and potassium, as " interstitial diuretics." These salts, whose action was mainly due to the kations (Ca and K), but partly also to the Cl, acted by dehydrating the tissue colloids. Sodium chloride, on the other hand, caused a hydrating of the colloids and opposed the action of the calcium salts. This antagonism of calcium and sodium was of great importance in view of the fact that they were the commonest constituents of our natural spring waters. Three well-defined types of mineral waters possessed diuretic properties—the sulphur water, including the sulphuretted salines, the calcareous, and the radio-active thermal waters of low mineralisation. Since the sulphuretted salines contained sodium chloride their diuretic action presented a problem.

Recent observations by Keller at Rheinfelden, and Violle at Vittel showed that NaCl was definitely inhibitory of diuresis. The latter concluded that each of the elements of a water, conceived as ions, had its own peculiar action and that only when there was a certain definite relationship between the various elements of a spring water was there any physiological property or therapeutic value. These relative proportions were comparatively rare among the considerable number of natural springs. Violle's experiments were of great importance as indicating why two waters of approximately similar composition so often differed widely in their actions, but Dr. Buckley thought that the results would have been more valuable had the artificial solutions used been of nearly the same strength as the natural spring water of the Grand Source. It might well be that the weaker natural solution was more powerfully diuretic owing to its higher degree of ionisation. Violle found that the diuretic action of a water was neutralised when the number of Na ions was half that of Ca ions, yet Zeller found that NaCl solutions, administered either orally or intravenously, produced a diuresis, and Keller found that NaCl notably increased the excretion of urea. The problem was, therefore, a complex one and might be affected by the diet and amount of fluid drunk before the test, as was suggested by the observations of Baird and Haldane. Certain effects of calcareous waters upon metabolism were also of importance. Kionka, in 1900, showed that calcareous waters tended to diminish the urea in urine, and in 1921 Miyadera found that this effect was produced without affecting the total nitrogen metabolism. Observations on the blood showed that the urea content was progressively diminished.

No experimental observations upon the effects of the third or radio-active type of waters had been published, but the clinical evidence of their diuretic effect was overwhelming. Such waters contained a large number of mineral salts in such minute quantities that they were almost completely ionised, as well as being charged with considerable amounts of gas—nitrogen, carbon dioxide, argon, and helium; they were radio-active owing to the emanation or "niton" which they contained. Experiments with artificially-produced radio-active solutions had not produced results comparable with those of the natural waters, perhaps owing to the lack of gaseous mineral constituents upon which the emanations might be supposed to have an adjuvant effect.

Dr. Buckley suggested that the explanation of the diuresis produced by the minute quantities of mineral salts in certain waters such as the Buxton mineral water might lie in their action on the pituitary body; in this respect the slight but definite and fairly constant fall in blood pressure after drinking this water was very suggestive, since slight stimulation of the posterior lobe of the pituitary caused diuresis with a fall in arterial pressure. Increased stimulation of the posterior lobe reversed this effect, and here again a parallel occurred in the case of a few patients in whom the ingestion of Buxton mineral water caused a diminution of the output of urine. In such cases, he suggested, smaller doses of the water might have the desired effect of diuresis by avoiding over-stimulation of the pituitary.

Discussion.

Mr. J. Race had investigated the comparative effect of Buxton thermal water and of distilled water in a number of cases of tophaceous gout. The method selected was to place the patient upon a normal hospital diet containing 50 oz. of fluid for several days until a general equilibrium was established and then to collect the urine over 24-hour periods; during the second period the normal fluids were supplemented by 20 oz. per diem of distilled water divided into three equal portions, and during the third period distilled water was replaced by mineral water. In some cases during a fourth period the effect of mineral-water baths on alternate days in addition to mineral-water taken internally was determined.

While the diet was slightly variable it was found that the nitrogen excreted in the urine was fairly constant, and that such a diet, being a normal one, did not cause digestive disturbances. In 16 cases the following average volume of urine was passed: Period i. (no extra periods), 1066 c.cm.; ii. (distilled water), 1349 c.cm.; iii. (mineral water), 1626 c.cm. In 11 cases in which the effects of baths were tested the following averages were obtained: Period i., 1113 c.cm.; ii., 1409 c.cm.; iii., 1693 c.cm.; iv. (mineral water and baths), 1745 c.cm. From these figures it appeared that the diuretic value of mineral water was much superior to that of distilled water; with the former 98 per cent. of the extra fluid was excreted in the urine, while with the latter only about 50 per cent. was excreted. The baths at a temperature of 96°–98° F. did not materially affect the amount of diuresis. In all cases the increase in the flow of urine was slightly less than the amount of extra fluid ingested. Concurrently with the increased flow of urine the total amount of salts and solids in the urine was also raised by mineral water drinking. Thus the figures for sodium chloride were: Period i., 7·4 g. per diem; ii., 7·8 g. per diem iii., 8·2 g. per diem; iv., 9·5 g. per diem. A most important feature of the diuresis obtained by mineral water was the reduction in the hydrogen-ion concentration of the blood, which allowed of a greater solubility of sodium urate, and tended towards a more complete nitrogen metabolism. Thus the average amounts in grammes per diem of urinary nitrogen appearing as urea and as uric acid respectively were: Period i., 7·65 and 0·128, ratio 59/1; ii., 7·72 and 0·117, ratio 66/1; iii., 7·85 and 0·113, ratio 69/1. The increase in the total amount of nitrogen excreted was small but quite definite, while the uric acid content of the blood was reduced on the average by 25 per cent., although the amount excreted in the urine was actually diminished. From this it would appear that there was a reduced absorption of uric acid precursors from the intestines, or an increased destruction of uric acid, or a reduced production of uric acid in intermediary metabolism. Possibly all three actions occurred.

From his observations Mr. Race concluded: (1) that the natural Buxton mineral water had a diuretic effect superior to that of distilled water; (2) that it increased the elimination of sodium chloride; and (3) that it decreased hydrion concentration and favourably influenced metabolism.

Dr. Fortescue Fox suggested that the periods i., ii., iii., and iv. should be more prolonged in future experiments since some persons were affected over long periods by a short period of mineral water drinking. In the baths experiment the temperature of the water was very important.

Dr. W. Langdon Brown commented on the smallness of the variation in nitrogen excretion produced by mineral water drinking which lay well within the normal range of variation produced by diet. Throughout the discussion it was assumed that diuresis was beneficial to the patient. That this was not necessarily so might be seen from the condition of patients suffering from diabetes insipidus. Without having heard the President's introduction he (Dr. Langdon Brown) made similar observations upon the probable effect of the endocrine factor in diuresis. He had recently suggested that the pituitary body regulated the threshold of the kidney for water. The effect of light, warmth, and climate upon the surface of the body acting upon the sympathetic system was also a factor in the problem.

Dr. Halls Dally, Dr. J. B. Burt, and Dr. W. Edgecombe (who referred to the extreme difficulty of obtaining accurate and reliable figures in experimental work of this kind and also described the diuretic effects produced by the two types of salines at Harrogate) also spoke.

Dr. Buckley, in reply, agreed that it was necessary to emphasise that diuresis if it concerned water alone was not an object to be aimed at, but if with the increased excretion of water went an increased elimination of waste products in solution a very useful end was attained, and even more important was the associated effect upon metabolism indicated by Mr. Race's experiments. He did not attach any special importance to the increased excretion of urea, but to the variation in the urea-uric acid ratio in respect of which the criticisms as to the influence of variation in diet, &c., had not the same force. His remarks on the action of saline waters had not been intended to belittle their value, but to indicate the trend of modern criticism as to the mode by which they produced their beneficial effects.

SECTION OF ANÆSTHETICS.

A meeting of this section was held at the Medical Institute, Birmingham, on Dec. 1st, Dr. A. L. Flemming, the President, being in the chair. Dr. K. B. Pinson read a paper on the

Condensation of Dimethyl Ether and Its Use as an Anæsthetic.

Having stated the reasons for believing a gas to be as such better fitted for use as an anæsthetic then a liquid, Dr. Pinson said that dimethyl ether is a gas at normal temperature and pressure. Its physical properties are not known. He found that it boiled at 24° C., and that at 100° C. it exerted a pressure of 97 pounds to the square inch. It can be safely compressed into cylinders at ordinary temperatures. Dr. Pinson was able to obtain only a small quantity for experiment. The gas condensed into a thin mobile liquid with slightly ethereal pleasant odour.

Mr. L. P. Gamgee read a paper on

A Surgeon's Thoughts on Anæsthesia.

He pleaded for close coöperation between surgeon and anæsthetist. Troubles often arose because an operation started before anæsthesia was deep enough, and this might be the fault of the anæsthetist for letting the surgeon begin, or the surgeon's fault for ignoring the anæsthetist's warning. When operations on the thyroid gland were contemplated the administration of the anæsthetic should not begin until the surgeon was ready to operate at a moment's notice. In his opinion lightness of anæsthesia added to the risk of shock in some operations; moreover, it might lead to inefficiency of the operation. When in abdominal operations the surgeon was hampered by the character of the breathing he should desist from his manipulations until the abdominal movements were satisfactory. This was generally secured by getting the patient more deeply under or by changing the anæsthetic. Mr. Gamgee did not like either morphia or scopolamine before operations. He asked why the Vernon Harcourt apparatus was not more frequently used, and believed that operating theatres were often kept at too high a temperature.

The President advocated the provision of recovery wards.

Mr. W. Billington dwelt on the danger of acetonæmia following on the use of scopolamine and morphia. He preferred small doses of omnopon longer before the operation than the usual practice. Plenty of fluid should be given both before and after operation.

Prof. F. Hobday demonstrated his regulating apparatus for giving chloroform to animals. Dogs had proved, he said, excellent subjects for chloroform, contrary to the common opinion, when the drug was properly administered.

Dr. Walter Jordan related his long and successful experience as to chloroform at an orthopædic hospital, and Mr. Kirkby Thomas demonstrated a new intra-tracheal apparatus.

After the meeting, dinner was given at the Union Club to those members who had come from London and other towns away from Birmingham. The travellers were much indebted to their Birmingham colleagues for their hospitality.

MEDICAL SOCIETY OF LONDON.

A meeting of this Society was held on Dec. 10th at 11, Chandos-street, Cavendish-square, W., Dr. Herbert Spencer in the chair.

Mr. Eardley Holland opened a discussion on

Intracranial Hæmorrhage in New-born Children: Its Pathology, Effects, Treatment, and Results.

During the past few years, he said, the interest taken in fœtal and neonatal pathology had shown a remarkable revival, and an immense amount of material had been investigated under grants from the Ministry of Health and the Medical Research Council. No one interested in the subject could omit to study the pioneer work published 32 years ago by Dr. Herbert Spencer under the title "On Visceral Hæmorrhages in Still-born Children." This work had not received the prominence it deserved; not only had all Dr. Spencer's conclusions held good, but the only new observation made in cranial pathology was that on injuries of the dura mater septa.

Intracranial hæmorrhage was a prolific cause of fœtal and neonatal death, and the prevention of its high mortality an urgent problem of preventive medicine. The majority of these fœtuses, apart from a certain number that were premature, were otherwise sound; they were in a totally different class from the macerated fœtuses that died before labour from some maternal, fœtal, or placental disease. Ætiologically intracranial hæmorrhage could be divided into two groups, traumatic and asphyxial, the former being vastly more important.

Behaviour of the Fœtal Head under Stress.—The fœtal head was a fragile object whose structure displayed a remarkable combination of qualities which enabled it to resist injuries, with defects which disposed it to suffer them. In the birth canal the head was subjected to the action of compressive forces which were the resultant between the powers of labour and the resistance of the maternal passages. The head was therefore in a state of stress during labour—a state which might conveniently be termed "cranial stress." This stress might be regarded as consisting of two elements, a general compression of the whole head and a simple longitudinal compression by opposite forces acting at the ends of the long diameter of engagement of the head in the pelvis. The fœtal head consisted of a non-rigid shell composed of loosely-jointed plates of pliable bone jointed on to a rigid base and strengthened by the attachment of the dura mater and its system of septa. The outstanding feature of the fœtal head was its ability to undergo changes in shape or moulding when subjected to stress. Alteration in shape was brought about partly by a displacement of the bony vault as a whole, and partly by bending of the individual bones which composed it. The displacement of the vault as a whole took place chiefly at the junction of the plate with the base of the occipital bone, a hinge joint which allowed a considerable range of movement forwards and a smaller range backwards. By far the commonest alteration in shape was elongation in a vertical direction with corresponding shortening in the antero-posterior direction. (Slides were shown dealing with the mechanics and results of traumatic intracranial hæmorrhage.) A certain amount of stress occurred in every labour, and in every labour there was a certain amount of head-moulding, but excessive stress gave rise to a dangerous degree of alteration in shape.

Excessive Cranial Stress.—The most important circumstances under which excessive stress and extreme alteration of the shape of the head might occur were disproportion between the head and the maternal pelvis, deficient flexion of the head, and great rigidity of the maternal pelvic floor. The forceps might cause injuries when applied too early or with too great force, when misapplied to the antero-posterior diameter of the head or used to deliver a premature fœtus, or when the fœtus was delivered too rapidly. The septa were much better able to resist a slow than a too rapid head-moulding. In a breech labour the after-coming head was rapidly, though comparatively momentarily, compressed in a series of diameters lying between the forehead and the occiput; thus tearing of the septa was liable to occur as a result of breech labour. He believed that the hæmorrhage generally came from the vein of Galen. Any movement of the apex of the tentorium was necessarily transmitted to the vein of Galen, whose fixed point was at the entrance to the straight sinus. The vein might become kinked, stretched, and engorged, and the main vein or some of its tributaries were easily ruptured. Failing detection of the ruptured vessel, a valuable clue to the origin of the hæmorrhage was its exact situation in the subdural space and its relation to surrounding structures.

Fœtal Asphyxia.—When the circulation of the umbilical cord was obstructed, or the placenta became widely separated or extensively degenerated, the fœtus passed into a state of asphyxia. Most observers agreed that asphyxia was the cause of death in from 30 to 40 per cent. of fœtuses who died during labour. Differentiation between traumatic and asphyxial hæmorrhage was not always possible, and in many cases both factors had existed. Observers differed as to their relative frequency. In his own 92 cases of cerebral hæmorrhage he placed 75 in the traumatic and 17 in the asphyxial class.

Sites and Extent of Intracranial Hæmorrhage.—The hæmorrhages might occupy (1) the subdural space, (2) the lateral ventricles, or (3) the cerebral substance. They were diffuse, and often occupied more than one site—a point of great clinical importance. Hæmorrhage might be severe, moderate, or slight; a large subdural hæmorrhage would spread into all the cranial fossæ as well as over the surface of the brain. Intraventricular hæmorrhage was much less common than the subdural type.

The Surgical Treatment of the Condition.—These cases were not suitable for operative treatment. The hæmorrhage was usually inaccessible at the base of the brain and in the region of the tentorium; also there were often associated visceral hæmorrhages elsewhere. Even if an infant were saved from death by operation, he would very likely become a member of the community who would have been better dead. He would rather show a mother her baby dead than have her reproach him afterwards with a paralytic and deficient child.

Dr. H. C. **CAMERON** followed. His paper is given in full on p. 1292 of this issue of THE LANCET.

Discussion.

Mr. **LAMING EVANS** said that he would limit his remarks to treatment and to the results of treatment. A surgeon was entitled to ask whether the spasticity arising from hæmorrhage was different from spasticity arising from primary neural degeneration of the brain. In orthopædic practice one dealt with the results of upper motor neural lesions; the results of treatment of acquired spasticity from cerebro-spinal fever, &c., were excluded from this discussion. Many methods of treatment of common deformities of the upper and lower extremities were available, but no surgical treatment was complete without special education of the patient. Fifteen years ago great hopes were raised by the operation of section of the posterior roots; he had used it in four cases, with no good result. The operation was now largely abandoned; the success claimed for it was, he thought, due to good after-treatment. Muscle education was important; he had never seen any benefit to result from electrical stimulation. Continuous stretching by means of movable or immovable appliances was of value. The two types of operation were, first, operations on muscles and tendons, and second, operations on the nervous system. The results of the former were better known. Twenty-five years ago tenotomy was almost universally used, but after this operation the case was always liable to relapse. The principle involved in tenotomy was now largely carried out by plastic elongation; he himself used this method where an over-correction was possible or where future function would be interfered with. In England neurectomy had long been used in cases of spasm; the object of this operation was to restore muscle balance by the paralysis of certain fibres, so that the remaining fibres could balance their antagonists.

Mr. H. A. T. **FAIRBANK** did not think that the origin of the rigid condition was of much consequence to the orthopædic surgeon; the latter had only to deal with results, provided that the active lesion was already finished with. He suggested that the age of 3 years was the time for operation; until then the child had not had a fair opportunity of learning normally how to walk. If at the age of 3 a child could sit up alone he would operate on arms or legs if they required it. Older cases were infinitely harder to deal with, because of anatomical shortening of spastic muscles and of ligaments. Before operation the child must make an effort to walk. Contra-indications to operations were idiocy, choreic movements, and fits—the last-named if they occurred with any frequency. Bromides should be given for a few days before and after the operation. Coming to details of operation in various sites, he found it best, if the whole obdurator nerve had to be removed, to open the abdomen. Surgeons were apt not to carry their operations far enough; it was well to remove more of a nerve than was now usually removed. With regard to flexion of the knee, he found operation on the sciatic nerve better than simple division of the hamstrings. In older children with anatomical shortening, however, he also divided the hamstrings. He believed in trying to select the operation most suitable to the individual case rather than in attempting to apply any exact rules. He found results in the arm much worse than those in the leg, the action of the arm not being automatic. If the child tried to walk he had to use both legs; the difficulty when he had one sound arm was to make him use the other. Lastly, apparatus should be used after operation; the final result of a case always depended on after-treatment.

Mr. L. G. **PHILLIPS** was chiefly interested from the obstetric point of view, and in causation and prevention. In the course of an inquiry carried out for the Medical Research Council, he had found that premature babies were four times more liable to have intracranial hæmorrhage than babies born at full term. The lesson to be learned from this fact was, he thought, that induction should not be attempted further back than 35 or 36 weeks, and that forceps should not be applied to premature babies if their application could be avoided. Of his 20 cases of intracranial hæmorrhage examined post mortem during the inquiry already referred to, four cases had followed toxæmia of pregnancy, being due to damage to the endothelium caused by the circulating toxin. The lesions in eclampsia and other conditions were chiefly due to cell degeneration resulting from this damage; the capillaries inside the skull probably suffered in the same way. In half of his 20 cases there had been a rupture of the veins covering either the cerebrum or the cerebellum. Only one case was of intraventricular hæmorrhage. Other injuries were unilateral and bilateral horizontal tears of the tentorium; there were a few cases of petechial hæmorrhage throughout the brain.

The **PRESIDENT** said that with regard to meningeal hæmorrhage resulting from damming back of blood in the veins, he had suggested 32 years ago that this was due to the depressibility of the lower angle of the parietal bone; this bone might press on the great anastomotic vein and cause engorgement. He would like to suggest to Dr. Cameron and others concerned with children's diseases that research into injury of the testes of new-born children would yield very interesting results.

Reply.

Mr. **EARDLEY HOLLAND**, in a brief reply, asked how many infants born with cranial hæmorrhage survived. It had been thought that none of them did survive, but he believed that a large number actually lived after a slight tear had occurred; in support of this view he recalled the fact that infants with enormous intracranial tears sometimes lived for a week. During the early part of the war he had come across a case of a baby which lived for two days, and showed post mortem an extensive healed tear in the left side of the tentorium. This case he had photographed; he had never come across another one.

Dr. **CAMERON** also briefly replied.

LIVERPOOL MEDICAL INSTITUTION.

A MEETING was held on Nov. 29th, Prof. J. HILL ABRAM, the President, in the chair.

Dr. W. **JOHNSON** read a note on

Acute Infectious Polyneuritis.

He said that amongst the rarer forms of multiple peripheral neuritis is that known as auto-infectious or acute toxic polyneuritis. He gave a short account of two cases he had seen recently, and pointed out that the disorder is usually ushered in by what the patient may describe as a "chill" or "influenza." There may be a variable interval between such a chill and the onset of the neuritic symptoms. These usually begin as sensations of numbness and tingling in the toes and fingers, followed by marked motor weakness in all four limbs. Soon the facial muscles become affected, and this observation, combined with, later, the occurrence of trunk muscle weakness, serves to indicate the correct diagnosis. Sensation is dulled over the distal portions of the extremities, but the sensory loss is usually much less marked than the motor loss. Apart from other forms of peripheral neuritis, the condition may simulate Landry's paralysis and acute ascending myelitis at the outset. The peripheral distribution of the symptoms, the disordered sensation, and the presence of facial paralysis are the chief points which would lead to the diagnosis of acute infectious polyneuritis. The cerebro-spinal fluid shows no definite change.

Mr. **LEYLAND ROBINSON** said that the disease in one of Dr. Johnson's cases might be associated with a transfusion of whole blood which had been carried out for post-partum hæmorrhage two weeks before the onset of the neuritic symptoms. Polyneuritis was recognised as a rare complication of parturition and due to pregnancy toxæmia (pernicious vomiting) or puerperal septicæmia, both of which could be excluded in this patient. The clinical features so closely resembled the type seen in France during the war as to suggest a common ætiology, and although the donor gave no history of neuritis, he had served in France and might be a carrier of the disease. The patient had subsequently become pregnant and had been delivered by Cæsarean section at full term; pregnancy and the puerperium were uneventful.

Mr. G. P. **NEWBOLT** read a note on four cases of

Intestinal Obstruction Caused by Gall-stones.

Three of the cases were women, all of whom recovered, one case was a male, who died. The symptoms were those of intestinal obstruction. Fæcal vomiting with intermissions was present. Constipation was not absolute and there was not much abdominal distension. The patients were all stout and elderly, one woman weighing 19 st. The chemical examination of the last stone removed was that of a typical gall-stone.

Mr. G. C. E. **SIMPSON** said that he had seen two cases of this condition, both in women. One, aged 70, died of pneumonia after operation. In the other case gall-stones were diagnosed, but the vomiting passed so insensibly into the vomiting of obstruction that some days were lost; in the latter case on exploration the adhesion of the gall-bladder to the duodenal angle was seen and two stones were felt firmly impacted low down in the common duct. Presumably the fistula first formed in the initial severe attack, the only attack accompanied by jaundice, six months before the big stone passed, and gave rise to obstruction. Operation on the biliary region had not yet been undertaken.

Dr. C. O. **STALLYBRASS** read a paper * on the recent outbreak of

Encephalitis Lethargica.

Having referred to the past history of the disease, he stated that whilst it was not new its pandemic extension was a new feature. As the disease spread there had been observed in France, Italy, &c., a tendency to evolve from a type presenting depression of function to one exhibiting exaltation of function; instead of palsies, lethargy, and somnolence, there were involuntary movements, delirium, and sleeplessness. In Liverpool, in 1921, 81 per cent. of the cases were of the first type. In the winter 1922–23 a considerable outbreak involving over 100 cases occurred and only 52 per cent. were of the first type. The delirium was usually occupational. Alteration in type was accompanied by increased fatality as well in the lethargic as in the over-active type; age-incidence was identical in both types. A definite history of contact with a preceding case was found in 9 per cent. of the cases. Dr. Stallybrass described four abortive cases. The virus he regarded as a variable one, which at times exhibited marked malignancy and increased pathogenicity, as at Derby, Rudduvoorde, and, probably, at Mülheim.

Dr. A. G. **GULLAN** stated that he had first seen cases of encephalitis lethargica at the end of 1919, when they were of the lethargic type, and though they were not paralysed the patients lay motionless in bed, were only roused with difficulty, and spoke in a monotonous, toneless voice. The only interest the patients took was, that in a feeble voice, they asked "whether they were going to recover." He agreed that the expressionless face was the most characteristic symptom of the disease, both in the lethargic and in the restless varieties. In 1922 he saw a considerable number of cases of the excited form in which choreic movements, wakefulness, and in some instances occupational delirium were present. Dr. Gullan stated that his mortality was considerably lower than that given for the whole of Liverpool; at the present time he had a case of the lethargic type in his wards which gave a previous history of trauma.

Reviews and Notices of Books.

PATHOLOGICAL PHYSIOLOGY OF INTERNAL DISEASES.

By ALBION WALTER HEWLETT, M.D., B.S., Professor of Medicine, Stanford Medical School. London and New York: D. Appleton and Co. 1923. With 151 illustrations. Pp. 765. 35*s*.

THE proper understanding of the normal functions of the body and of the manner in which they may become deranged in disease is the basis of scientific medicine. To keep abreast of recent work in physiology, biochemistry, immunology, and the like is, however, by no means easy, and implies leisure for reading and access to literature which the general practitioner is rarely fortunate enough to enjoy. Prof. Hewlett's book meets the demand so often expressed for a critical and reliable guide to modern pathological physiology. Dealing with the circulation, digestion, metabolism and its disturbance, fever, the derangement of respiration, renal function, infection, the blood, the nervous system, and the endocrine organs, he describes the functional changes brought about by disease and discusses their causation. He does so in a clear and readable manner, avoiding controversy when possible and presenting a definite point of view. The reader is presented with a clear and concise picture of disease, and an adequate bibliography is appended to each chapter for the benefit of those who may desire to extend their reading to the original sources. As is only to be expected in a subject of such dimensions, certain of the sections are more satisfactory than others, but on the whole the book is well balanced throughout, and may be confidently recommended to students and practitioners alike.

CHRONIC INTESTINAL STASIS—A RADIOLOGICAL STUDY.

By ALFRED C. JORDAN, C.B.E., M.D., M.R.C.P. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 230. 25*s*.

ALIMENTARY delay, or constipation in its widest sense, is of immense importance to human well-being, and the radiologist—to whom the viscera are not the sealed book that they are to others—is in a better position than most to make exact observations. In his preface, Dr. Jordan says, "I have attempted to give an ordered account of chronic intestinal stasis. I have found it a difficult task, so interwoven are the effects of stasis. There is unavoidable repetition, and I hope my readers will forgive this, especially as the repetition is more apparent than real and is, in fact, a presentation of the subject from many aspects." To this volume Sir Arbuthnot Lane contributes a

---

* See also THE LANCET, Oct. 27th, p. 922.

"foreword," so that we know from the start we are reading the work of a follower of the doctrines of Lane. Those who wholeheartedly accept these doctrines will, no doubt, find the study completely satisfying.

Dr. Jordan is safest and best when he is examining the intestinal viscera almost wholly from the point of view of the skilled radiologist. Thus, following his brief summary of the developmental causes of "stasis," he proceeds to deal with the intestinal tract under the chapter headings of the Large Intestine in Chronic Intestinal Stasis; the Pelvic Colon in Stasis; the Peristalsis of the Large Intestine; Colitis; Diverticulitis; the Ileal Kink; Ileal Torsion; the Undescended Cæcum; the Appendix. All of these conditions are well described and appear to the reader to be really close to his subject. A good case is made out for including studies of duodenum and stomach. In regard to cardiospasm, no doubt "stasis" may be one of its causes, although treatment on the lines recommended by the author will, we think, not always be successful. Dr. Jordan would have us believe that chronic intestinal stasis will cause such varied conditions as chronic mastitis, certain forms of blindness, disseminated sclerosis, epilepsy, aortic aneurysm, fibroid phthisis, gall-stones, glycosuria, Dupuytren's contraction, and cancer. Now intestinal disorders are common, while a number of the diseases enumerated are relatively uncommon. Some of the illustrations given are very striking, and the association of two apparently unrelated conditions is often curious and suggestive; but it must be remembered that the citation of a number of cases in which these diseases were present and associated with intestinal derangement is not in itself proof.

Radiological technique has reached a high degree of precision, but even now the illustrations so obtained are difficult to interpret. In spite of the carefully numbered and lettered descriptions, some of them will leave the reader with an open mind. It would, perhaps, be better if in a later edition Dr. Jordan enlarged the book in the direction of making it a complete work on radiological investigation of the intestinal tract alone, or confined it rigidly to advancing proofs of the correctness of Lane's hypothesis. In either sphere his experience would be welcome and carry weight.

EXERCISE IN EDUCATION AND MEDICINE.

Third Edition. By R. TAIT MCKENZIE, M.D., LL.D., late Major, R.A.M.C.; Professor of Physical Education and Director of the Department, University of Pennsylvania. London: W. B. Saunders Company. With 445 illustrations. Pp. 601. 24*s*.

ALL those who are interested in physical work, whether educational or gymnastic, have grown accustomed to look forward to reading anything from the pen of Tait McKenzie. The rare combination of physician, sculptor, and university professor has qualified him to produce a standard work on the subject which he has made particularly his own. The book is divided into two sections, the first of which is devoted to exercises in education, and the second to exercises in medicine. The first part gives a most comprehensive survey of the subject, and deals largely with history, comparing the systems of gymnastic education in vogue in various countries with admirable precision and clearness. It is mainly in these pages that the value of the combination of medical man and sculptor is so clearly shown. It is perhaps unfortunate that more reference has not been made to the attempts that are now being made throughout our national schools to pay serious attention to the physical fitness of the children attending them; for, although the system is still in its infancy, it has made such rapid strides as to be worthy of comment. At the same time, it cannot be denied that the perusal of the account given of educational gymnastics in other countries is, in places, inclined to fill the British reader with an envious admiration. More particularly will this be the case amongst those who have had the opportunity of seeing the author's magnificent work in his own University at Philadelphia.

A glance through the titles of the 17 chapters in this section of the book shows at once its comprehensive scope, since even the physical education of the blind and the deaf-mute is given full consideration. The chapter devoted to the physical education in girls' schools and women's colleges places the pros and cons of this much-debated subject with great clearness, and a careful study of these pages by those who have joined in the acrimonious discussion of this subject would speedily clear the ground for a more ready settlement of divergent views. In the section dealing with exercises in medicine the author changes his rôle from that of the sculptor and scholar to that of the medical practitioner. He has, of course, found it impossible entirely to separate treatment by exercise from treatment by other physical means; and a certain amount of consideration has been devoted to treatment by massage, though other methods, such as electrical treatment, have received but passing mention. One of the outstanding features of treatment by exercises prescribed by the author is the frequency with which his patients are instructed to carry out certain stated movements. Almost the whole field of physical therapeutics is covered by the book. Its title may lead to the impression that it is only intended for the masseur-gymnast and physical-therapist. It is to be hoped that others, too, will study its pages. There can be few medical men who would fail to derive much practical help therefrom in the treatment of patients.

BIOLOGICAL TECHNIQUE.

Handbuch der biologischen Arbeitsmethoden. Herausgegeben von Geh. Med.-Rat. Prof. Dr. EMIL ABDERHALDEN, Direktor des Physiologischen Instituts der Universität Halle a. d. Saale. Abt. IV., Teil 3, Heft 2, Lieferung 106, Blutuntersuchungen. Berlin und Wien: Urban und Schwarzenberg. 1923. Pp. 514.

THIS number of the "Handbuch der biologischen Arbeitsmethoden," now appearing under the editorship of Prof. Abderhalden, will be of particular interest to students of the blood. Each of the seven sections is written by an authority who has himself contributed to the sum of knowledge on his subject, and, in consequence, all contain matter not available in any previous handbooks. But little attention is given to theoretical considerations; the whole purpose of the work is practical, and the details of all the procedures described are fully and clearly set forth. The first two sections will be of least interest to workers in this country; in the former Hamburger, of Groningen, describes an accurate method for estimating the fragility of the red cells, which is undoubtedly a great advance in technique on Widal's original method, but has the disadvantage of requiring rather elaborate specially made apparatus; in the latter Reiss, of Frankfurt-am-Main, describes the newer methods of refractometry of the serum. In the third section Kleinmann, of Berlin, goes very fully into the theory and practice of colorimetry and nephelometry; this is a most valuable contribution. Fahraens, of Stockholm, in the fourth section deals with the suspension stability of the red cells; this subject, interesting though it be academically, offers little promise of useful clinical application, and has attracted little attention in this country. It is interesting to note that the first true observation on this matter was made by an Englishman, or rather Briton—Hewson—who in 1772 demonstrated that the formation of a "buffy coat" depended upon sinking of the red cells before clotting had occurred. The author points out the fact, not usually recognised, that diminution of the suspension stability depends not upon retardation of clot formation, but is due to the clumping of the red cells, the fall of the cells being the more rapid the larger the clumps formed. In the fifth section Degkwitz, of Munich, details a number of procedures applicable to the study of the blood platelets, and in the sixth and seventh Schelcht, of Duisburg, and Frank and Seeliger, of Breslau, respectively have collected and fully described a large number of histological procedures of the greatest value in the study of the blood and hæmatopoietic systems.

The Examination of Patients.

By Nellis B. Foster, M.D., Assistant Physician to the New York Hospital; Associate Professor of Medicine at Cornell University College of Medicine. London and Philadelphia: W. B. Saunders Company. 1923. Pp. 253. 18*s*.

Dr. Nellis Foster is familiar to many readers in this country as the author of a number of penetrating studies and illuminating lectures on clinical medicine. His new book will be greatly appreciated by those who prefer an account of the everyday methods of one skilled physician to the generalities of the ordinary text-book. Dr. Foster here records his routine in the examination of patients, and the precision of his writing, the thoroughness of his method, and his critical but sympathetic attitude to recent advances, make his book a most valuable one to all those engaged in general practice. We do, however, feel that the book loses a great deal through the omission to include descriptions of the clinical examination of the blood and lymphatic systems and of the urine. We can imagine the practitioner turning to this volume in a hundred difficult situations, and receiving the greatest service from the author's description of examination of a cardio-vascular, gynæcological, or neurological condition. But should his patient be one with a grave anæmia, or an obscure splenic enlargement, he will not get the same assistance. We hope that future editions may see these omissions corrected.

Loeb Classical Library.

Hippocrates. Vol. II. With an English Translation by W. H. S. Jones. London: Heinemann. 1923. Pp. 336. 10*s*.

A review of the first volume of this edition of the text, with a translation of the Hippocratic Corpus, appeared in our issue of Sept. 8th. This volume contains the following treatises: Prognostic, Regimen in Acute Diseases, The Sacred Disease, The Art, Breaths, *περὶ φυσῶν*, Law, Decorum, Physician (Cap. I.), and Dentition. The Introductory Essays contain, amongst others, one upon Ancient Nursing, derived from information contained in the treatises Epidemics, Regimen in Acute Diseases, and Decorum, from which it appears that the nursing was carried out by a pupil—i.e., by someone more or less fully trained. Another essay deals with the subject of Ancient Medical Etiquette, or rather Medical "Good Form," the information being derived from the treatises The Oath, Law, The Physician, Decorum, and Precepts.

Perhaps the most interesting treatise in this volume is that upon The Sacred Disease, which, mutatis mutandis, might have been written by Erasmus. The writer considers that no one disease is more divine than another, "all are divine and all human. Each has a nature and power of its own; none is hopeless or incapable of treatment." The term "Sacred Disease" apparently includes not epilepsy alone but any convulsive affection—e.g., the writer's description of the disease in cattle and goats seems to refer to hydatid of the brain (p. 169). Two other notable treatises are those entitled Law and Decorum. Mr. Jones suggests, with great probability it seems to us, that these two treatises, and possibly Precepts as well, deal with matters discussed and only known to medical men who belonged to a guild or secret society. Thus the last sentence of Law ends as follows: "Holy things are shewn to holy men; to the profane it is not lawful to shew them until these have been initiated into the rites of knowledge." In Precepts V. a genuine physician is called "one made a brother." The expression "Holy things for holy persons" is a common religious formula, and we may point out that it has survived to this day, with a slightly different application, in the Eastern Liturgies, such as those of Chrysostom and Basil, where at the Elevation the priest says: "The Holy things are for the holy" (*τὰ ἅγια τοῖς ἁγίοις*), while in the West we find the same phrase, "Sancta Sanctis," in the Mozarabic and Gallican Liturgies,. Although the latter is not now in use, the former is daily said in the Cathedral of Toledo.

JOURNALS.

British Journal of Ophthalmology. — The original articles in the October number are physiological. The Blood Pressure in the Eye and its Relation to the Chamber Pressure is the title of an article by Priestley Smith, in which many problems are discussed, such as the self-adjusting equilibrium of pressure inside and outside the retinal veins, the venous pulse and its relation to finger pressure, &c. The author is one whose researches are always valuable. The second article is by H. Herbert on the Pectinate Ligament in its Relation to Chronic Glaucoma. The anatomy of the ciliary region is still a subject about which complete certainty has not yet been established. In this article the scleral spur discovered by Prof. Thomson, of Oxford, on which his "pump action" theory is founded, is criticised as not having been found in the eyes examined by Herbert. According to Herbert there are striking anatomical variations in the mode of attachment of the longitudinal fibres of the ciliary muscles, some types involving a greater predisposition to glaucoma than others.——The November number is a clinical one. The first article by W. Barrie Brownlie and H. Neame calls attention to a risk that attends upon the ordinary operation of advancement of a rectus muscle. A case is given in which an advancement operation was followed in a few months by the appearance of an implantation cyst of the iris and ciliary body. In spite of a large iridectomy, which included all the anterior wall of the cyst, its recurrence was inevitable, and ultimately the eye had to be excised. Such a disaster as this, though of course extremely rare, ought to be a warning to all operators. The position of the cyst, as determined by pathological examination, suggested that the needle carrying one of the sutures was passed too deeply, and traversed the anterior part of the ciliary body at its junction with iris root and pectinate ligament. The advancement operation had not been performed by the author of the article, but he charitably remarks, "Who will say conscientiously that he has never left a suture in the deep ciliary region or even deeper?" A case of cyst of the sclera following upon an advancement operation was reported in 1921 by C. Goulden and M. H. Whiting at a meeting of the Ophthalmological Society, and in the discussion that followed Mr. Cyril Walker spoke of a cyst following an advancement operation which projected both externally and internally. In this case, however, the growth stopped spontaneously. To avert such a disaster as is here narrated it is necessary not only to avoid penetrating too deeply into the sclera with the needle, but also to keep the overlying conjunctiva well out of the way so as to mitigate any risk of it being carried into the wound along with the needle. Sanford R. Gifford writes of intra-cisternal injections in the treatment of luetic atrophy, and J. J. Keegan of the technique and reaction of intracranial bichloride injections. The latter author admits that the constancy and severity of the immediate reaction from the injections make this a rather heroic procedure. Nevertheless, the first author reports improvement of vision in five cases, the best results being obtained in early cases with relatively good central vision, at least in one eye, and with little evidence of other nervous involvement. The fourth article in this number, by A. W. S. Sichel and A. R. Fraser, reports a case of hemianopia as the sole clinical feature in untreated secondary syphilis.

The Medical Clinics of North America are published bi-monthly, and the price of a year's issues, which comprise a complete volume, is 55*s*.

THE LANCET.

LONDON: SATURDAY, DECEMBER 15, 1923.

ORAL SEPSIS AND CANCER.

In a recent paper[1] Mr. F. St. J. Steadman has collected a considerable amount of evidence, chiefly indirect, to support the view that prolonged sepsis in the mouth might predispose to cancer of the alimentary canal. He comes to the conclusion that oral sepsis is "one of the commonest, and probably the commonest, predisposing cause of cancer of the alimentary canal and its associated parts." He points out that cancer of the alimentary canal accounted for 63 per cent. of the total mortality from malignant disease in 1901 to 1904. He has examined 204 cases of cancer of the alimentary canal, and found that practically all were suffering from pyorrhœa. As a control an examination of over 800 individuals free from cancer showed that pyorrhœa was present in 88 per cent. Mr. Steadman grouped the cases into three categories, according to whether the pyorrhœa was slight, moderate, or severe, and from the figures obtained he has constructed what he terms the "maximum pyorrhœic index." The index figure obtained from examination of the cancer patients was 91·6 per cent., while that of the cancer-free individuals was only 53·3 per cent.

On these data Mr. Steadman has come to the conclusion that the majority of persons with cancer of the digestive tract have advanced pyorrhœa, while the latter is less common in persons free from cancer. Mr. Steadman has quoted statistics from the Registrar-General's reports; it is a little surprising that he has not grouped the cases of cancer of the alimentary canal according to sex as well as to their anatomical distribution. If this is done we find that although the total number of deaths from cancer of the alimentary canal is approximately equal, though actually greater in the male, yet the deaths from cancer of the buccal cavity are in the proportion of seven to one in males and females. In 1921 the deaths from cancer of the mouth were in males, 1482; in females, 358. The total death-rates from cancer of the mouth in males and females in the ten years from 1911 to 1920 show a similar proportion. If oral sepsis is such a common predisposing cause of cancer, then we might expect its influence to be most marked in the region in which the sepsis occurs. On this hypothesis it appears difficult to account for the comparative rarity of cancer of the mouth in females. Now if it could be shown that pyorrhœa had a sex incidence similar to that of cancer of the mouth it would help Mr. Steadman's views. It is, however, quite certain that pyorrhœa is little, if at all, less frequent in women, though actual statistics do not appear to be available; and it is significant that the deaths from disease of the teeth and gums for 1922 were for males, 156, for females, 149. These figures are difficult to reconcile with Mr. Steadman's conclusions. In cancer of the tongue it is generally supposed that excessive smoking and syphilis play an important rôle and partly explain the preponderance of cancer of the mouth in males; but both of these forms of chronic irritation are certainly less common than pyorrhœa. With regard to gastric ulcer and its relation to cancer of the stomach, Mr. Steadman takes it too readily for granted that the ætiology of gastric ulcer is a settled matter. There is considerable diversity of opinion as to whether gastric ulcer is a frequent precursor to cancer of the stomach.

We do not find that the evidence Mr. Steadman adduces is sufficient to prove the very definite statement he makes with regard to oral sepsis and cancer of the alimentary canal. Yet it does not follow that pyorrhœa is a negligible factor. It may well be that it acts by influencing other forms of irritation rather than by acting as an independent predisposing cause of cancer. Thus, syphilis or excessive smoking, or both together plus oral sepsis, may represent a degree of irritation far more likely to lead to cancer of the tongue than when oral sepsis is absent. But in his attempt to establish oral sepsis as an important ætiological factor in the incidence of cancer in the alimentary tract generally Mr. Steadman appears to have forgotten his 865 control cases which did not have cancer. No less than 88·5 per cent. of these had periodontal disease, and even if we accept his pyorrhœic index 177 of these control cases showed a maximum degree of pyorrhœa. The presence of oral sepsis in the body cannot be other than harmful, but we should need stronger evidence than that put forward to attribute to it such a preponderant rôle in the causation of cancer of the alimentary canal.

◆

THE COMMERCE OF CURES.

Novel cures and fresh theories of the treatment of disease are sometimes received by the daily press and the public with an unguarded enthusiasm which bequeathes a legacy of disappointment to the sufferers who hope to benefit thereby. The great expectations of pathology are not always realised. "I've known over thirty men that found out how to cure consumption" (says the old doctor in Mr. Bernard Shaw's play); "why do people go on dying of it?" Even those prospective remedies of which high hopes are justly formed may require a protracted period of proof or preparation before they are available for the ordinary patient. The Spahlinger treatment for tuberculosis seems to be passing through this stage. Phthisical patients anxious to undergo this treatment are, it is said, informed that if they will subscribe a thousand pounds towards the cost of the remedy, or will take up a thousand pounds' worth of shares in the undertaking, all facilities for a cure will be forthcoming.

Exactly in what terms or circumstances or upon what authority any such proposal may have been made, we are not concerned to discuss. If the suggestion be unfounded, it still has an abstract interest for the medical profession. If a patient asked whether he should undergo such a treatment on such a condition, what advice should a doctor give? The Spahlinger system makes confident claims to success. A thousand pounds would not be an excessive price for the cure of tuberculosis. Statements have been made in Parliament which throw light on the present position. During the debate on the Appropriation Bill last August a critic of the Government and an advocate of the Spahlinger system mentioned that the undertaking was in financial difficulties, with liabilities of £100,000, and that the Ministry of Health had been pressed to find that sum and to guarantee £10,000 a year for three years. The official reply was that the Ministry was satisfied that there was a prima facie case for such further inquiry into the Spahlinger treatment as would enable medical authorities and the world in general to form a definite and final opinion as to its efficacy. It was suggested that Mr. Spahlinger should take an early opportunity of making a full statement of his process and results to a body competent to pass expert judgment on them. Last year, it was stated, the Ministry sent a specially qualified officer to Switzerland to acquaint himself with the treatment. Subsequently, in August, 1922, the Ministry made a proposal to Mr. Spahlinger which was unacceptable to him. Arrangements made between him and the Red Cross Society also broke down. Further negotiations between him and the Ministry had lately taken place. There, it seems, until financial assistance be forthcoming from private sources, the matter at present rests. The Ministry of Health can hardly be blamed for adhering to the official view that public funds cannot be embarked except upon the basis of adequate information and reasonable security.

---

[1] Brit. Dent. Jour., Dec. 1st, 1923.

It may be safely stated as a general proposition that professional opinion deprecates the association of therapeutic agents with such extraneous elememts as secrecy, guaranteed cures, newspaper campaigns, and company flotation. Apart from these considerations, however, neither ethics nor professional etiquette can qualify the obvious fact that if an expensive form of treatment is not yet commercially developed, the cost of applying it must be very high. The cost of remedies has sometimes been cheapened and production has been facilitated by the generosity of a rich benefactor or by means of a grant from public funds, and it is just as laudable, and certainly as practical, to subscribe to the development and application of a particular remedy as to subscribe to research in general. But with regard to the individual patient, it seems to us that the proposition turns on the answer to the question, "Has Mr. Spahlinger yet produced an agent which enables us to tell a patient that the payment of a definite sum will produce a definite benefit for himself?" Until any therapeutic agent, however promising, has reached such a stage, we are surely unjustified in promoting research on its behalf by appealing to the hopes or fears of the class of patient whom it is seeking to relieve. Should Mr. Spahlinger offer to treat a patient there is nothing in our law to prevent his asking whatever fee he cares to name; but he has no moral right to appeal to the sick to aid him in research, nor have those who support his demand any right to claim subsequent priority of treatment.

◆

THE SURGERY OF THE SYMPATHETIC.

The working of the organs of internal secretion is intimately bound up with the activity of the vegetative nervous system, and with the increasing study devoted to endocrine function it is not surprising that a great deal of attention has been directed to the physiology of the autonomic nerves. So that a real surgery of the sympathetic system has grown up. A few weeks ago the work of Leriche on the effects of arterial decortication was reviewed,[1] and the conclusion arrived at that an extended investigation of this method of treatment is necessary before any satisfactory evaluation can be made. The perusal of a striking monograph[2] just published by Prof. Thomas Jonnesco, of Vienna, on the surgery of the cervico-thoracic sympathetic, leads to the belief that this branch of the subject should also be very carefully considered and the possibilities of the operation therein described be further explored.

Briefly, Prof. Jonnesco recommends complete excision of the cervical sympathetic with extirpation of the stellate ganglion for exophthalmic goitre, angina pectoris, migraine, epilepsy, trigeminal neuralgia, and glaucoma. The arguments for a sympathetic origin of the symptoms of exophthalmic goitre are well set forth. It is held that whatever may be the beginnings of this obscure disease, certainly the symptoms are perpetuated by overactivity of the cervical sympathetic. The extirpation of this cord then is the logical procedure. Jaboulay was the first to operate upon the sympathetic for Graves's disease, but his operation soon fell into disrepute because it was found to be ineffective. This failure Prof. Jonnesco holds to be due to the fact that the superior ganglion only was destroyed, whereas many fibres reach the gland from the lower part of the cord. The cases described and illustrated by Prof. Jonnesco are very striking. He has operated upon 50 cases with four deaths. The immediate result in all the other cases was a very pronounced amelioration of the symptoms; and that the relief was permanent he was able to establish in the 14 cases which he was able to trace. The experiments of Cannon in 1915, who anastomosed the peripheral end of the cut phrenic nerve to the cervical sympathetic and was able to obtain certain of the symptoms of Graves's disease, demonstrated the important influence exerted by nerve impulses upon the thyroid, whilst Reinhard[3] has shown how chronic irritation of one cervical sympathetic led to hypertrophy of the corresponding lobe of the gland. The latter observer also has obtained very good results from Jonnesco's operation in eight cases. The technique itself demands a rather delicate dissection. It is illustrated by many beautiful plates in Prof. Jonnesco's monograph. In these the spinal accessory nerve is shown divided in every case, though in the text the author says he avoids it. Injury to this nerve would be a serious drawback to the procedure. A still more interesting section is that which deals with angina pectoris. The operation of sympathectomy, dividing as it does all the cardiac nerves, breaks the afferent path by which the crises are precipitated. In four cases the results were extremely good. W. B. Coffey and P. K. Bain[4] have recently reported their results of a more limited operation on the sympathetic for angina. In two of their patients complete freedom from attacks resulted, whilst in the others there was considerable relief. The efficacy of Jonnesco's operation in migraine, trigeminal neuralgia, and epilepsy is by no means established, whilst in glaucoma it would seem to be definitely contra-indicated.

Undoubtedly extirpation of the cervical sympathetic cord needs further study, and its main field of usefulness may prove to be the alleviation of suffering in angina pectoris.

Annotations.

"Ne quid nimis."

PANEL INQUIRY: TERMS OF REFERENCE.

The Minister of Health has approved the following terms of reference for the Court of Inquiry set up in connexion with the terms of remuneration for the insurance medical service after Jan. 1st, 1924:—

"To inquire and report to His Majesty's Government what should be the amount of the capitation fee (per insured person per annum) on the basis of which the Central Practitioners Fund under Article 19 of the National Health Insurance (Medical Benefit) Regulations, 1924, should be calculated as from Jan. 1st, 1924, so as to afford adequate remuneration for the time and service to be given by general practitioners under the conditions set out in those Regulations, in connexion with the medical attendance and treatment of insured persons, due regard being had to the service in fact rendered under the Regulations hitherto in force. This capitation fee is not to include any payment in respect of the supply of drugs and appliances (such payments being made out of the Drug Fund under Article 24 of the Regulations), or any payments to meet the special conditions of practice in rural and semi-rural areas."

It will be remembered that the personnel of the Court of Inquiry consists of Mr. T. R. Hughes, K.C., Mr. F. S. Goodenough, and Sir Josiah Stamp.

TRANSMISSION OF LEPROSY FROM RAT TO MAN.

In a paper in *Paris Médical* for Oct. 27th Prof. E. Marchoux, of the Pasteur Institute, discusses the possibility of the transmission of leprosy from the rat to man in connexion with a most instructive case. It was that of a man who, since 1910, had been treated in France and England for leprosy, and who finally drifted into the Pasteur Hospital under the care of Dr. Veillon. Superficially, the disease was limited to the limbs and face, where there were numerous brown patches. No cutaneous sensory disturbances were noted, but periodic pemphigoid eruptions had given rise to small round ulcers which had been slow to heal. There were numerous scars resulting from the slow healing of these ulcers, and when their surface or the nasal mucous membrane was lightly scraped and the substance thus obtained was examined under the microscope numerous fine, short, cocciform bacilli were seen, to which Prof. Marchoux has provisionally given the name *Mycobacterium pulviforme*. After the patient's death these organisms were found in great quantities in the skin, lymphatic glands, liver, and spleen; in the last-named organ they were particularly numerous. Rabbits, guinea-pigs, and rats were inoculated from this spleen, and whereas the rabbits and guinea-pigs were unaffected five of the six rats contracted a disease closely similar to, if not actually identical with, rat leprosy—a disease discovered in 1905 by Stefansky in sewer rats. Prof. Marchoux has worked with his virus since 1921; it is now in its fourth passage through rats, and the morbid changes evoked have shown no macroscopic or microscopic deviation from the changes associated with spontaneous rat leprosy. It would seem that the relation of rat leprosy to human leprosy may be somewhat similar to that of bovine to human tuberculosis; the micro-organism of rat leprosy may not find the human body congenial soil except under most rare conditions. Rat leprosy, by the way, would seem to be a comparatively common disease in the sewers of Paris, and it has been calculated that 0·6 per cent. of the Parisian sewer rats are definitely leprous, and that about 5 per cent. are infected to such a limited extent that the disease can only be detected post mortem. This is a point which Prof. Marchoux includes among the many parallels he draws between the leprosy of rats and man. For in man, too, the disease may be limited to the lymphatic glands, and in the French colonies the bacillus of leprosy has sometimes been found in the lymphatic glands of apparently healthy persons living in contact with definite cases of leprosy. Hitherto experimental cultivation of Hansen's bacillus has seldom, if ever, been successful, but the recent researches of Prof. Marchoux suggest that the anaerobic properties of the lepra bacillus are largely responsible for cultural failures in the past, and that future progress in this direction will depend on appreciation of this fact.

THE LEUCOCYTES IN MEASLES AND SCARLET FEVER.

Dr. H. K. Von Winterfeld and Dr. E. Hahne,[1] of the Rostock University Medical Clinic, examined the blood in 28 cases of measles and seven of scarlet fever, with the following results. In only two cases of measles was there absolute leucopenia (below 4000 leucocytes); normal leucocyte values (4000–8000) were found in 18 cases, and leucocytosis (8000–20,000) in four cases. In other words, the great majority of the cases showed normal leucocyte values, leucopenia was rare, and leucocytosis occurred only in complicated cases. As regards the differential count, of 25 cases of measles investigated 20 per cent. showed lymphopenia (below 20 per cent.), 28 per cent. normal lymphocyte values (21 to 29 per cent.), and 52 per cent. lymphocytosis (over 30 per cent.). Complete absence of eosinophils was found in 24 per cent., normal eosinophil values (1 to 3 per cent.) in 56 per cent., and eosinophilia (4 to 9 per cent.) in 20 per cent. The writers conclude that while the leucocyte values are not characteristic in measles, the presence of leucocytosis in uncomplicated cases contra-indicates measles, and lymphocytosis, as a general rule, is in favour of the diagnosis of measles. While the behaviour of the eosinophils is not characteristic in measles, high values are rare, and the possibility of their being due to intestinal parasites should be borne in mind, especially in children. In almost all the cases of scarlet fever there were leucocytosis associated with lymphopenia and a distinct eosinophilia during the eruptive stage. The eosinophilia persisted well into convalescence, so that in doubtful cases with indefinite desquamation without a history of a rash the combination of desquamation and eosinophilia justified a diagnosis of *scarlatina sine eruptione*. The writers' conclusions as regards the blood picture in scarlet fever are as follows: (1) Leucocytosis points to scarlet fever and against measles. (2) Lymphocytosis points to measles and against scarlet fever. (3) High eosinophilia points to scarlet fever, especially in convalescence, while normal eosinophil values do not exclude measles. (4) The leucocyte picture is of considerable value in the differential diagnosis between scarlet fever and measles, especially as the other signs supposed to be pathognomonic of measles, such as Koplik's spots and the diazo-reaction were frequently absent in the writers' cases.

MODERN MEDICINE IN ICELAND.

The conception of Iceland as a centre of medical science may seem a little startling, for we have been taught to associate this country with volcanoes, fogs, and ice rather than with the modern laboratory and hospital. But a jubilee number of *Laeknabladid*, which celebrates the sixtieth birthday of Prof. G. Magnusson, and which contains 12 original articles, shows that Iceland is not only in close touch with the outside world of medicine, but is also in the van of research. A paper by Dr. A. Arnason deals with the notifications of tuberculosis in a country district in the period 1890–1922, and the earlier date shows that, in the matter of notification, Iceland has been no laggard in the administrative control of tuberculosis. Approximately a quarter of the 102 tuberculous patients had tuberculous parents, and the majority had tuberculous brothers or sisters. One-half of the married tuberculous patients had children suffering from the same disease, but among the 30 married patients there was only one instance of tuberculosis in both husband and wife. At Dr. Arnason's instigation, a veterinary surgeon tested with tuberculin all the cattle (80 to 90) in a parish where the disease was most prevalent, but in no case was a positive reaction obtained. In an anthropological paper by Dr. G. Hannesson, who has carried out certain measurements of 844 Icelanders between the ages of 20 and 40, it is pointed out that the Icelanders are among the tallest people in Europe. All the hardships, poverty, bad housing, and the like, "which we have suffered ever since the country was first inhabited, have not been able to lower our stature. After a thousand years of adversities in darkness and cold on the verge of the Arctic zone the Nordic race still carries its head high and claims kinship with its neighbours on the eastern side of the ocean." A paper on 66 cases of placenta prævia by Dr. G. Thoroddsen is followed by a paper by Dr. G. Claessen on radiography. In a paper by Dr. G. Porsteinsson an account is given of 11 patients suffering from echinococcus of the liver. This would seem to be a common complaint in Iceland, and in another paper on the same subject by Dr. M. Einarsson it is pointed out that echinococcosis is fast disappearing in Iceland, and that for every 100 cases occurring 60 years ago there are now only 15. But there is evidently still much room for improvement, for in the period 1905–1923 he operated on 134 cases. A short paper on leprosy by Dr. S. Bjarnhjedinsson brings out the point that perforation of the palate is not a rare sequel to this disease. A paper by Dr. P. Sveinsson is a plea for influencing the subconscious mind of lunatics and habitual drunkards by means of fasting and drinking hot water, which cause the mind to concentrate on the sensation of hunger, diverting it from morbid notions and the craving for alcohol. This symposium of Icelandic medicine is highly creditable to its authors.

BONE NECROSIS AFTER AVULSION OF THE SCALP.

Dr. Erich Düttmann,[1] of Giessen, reports the case of a child aged 9, who was brought into the hospital with the history that eight days previously she had caught her hair in a machine in her father's mill, with the result that the whole scalp, together with the right ear muscles, were torn off. She was dressed by a doctor with trypaflavine, and this dressing was left in place until she was sent to the hospital. The case is reported to illustrate two methods of treating the necrosis that followed. A month after admission patches of granulations were present, but most of the cranium was uncovered by periosteum and necrosed. As the general condition of the child was very poor, and she complained of severe headache, it was determined to operate. On the left side the necrosed bone was removed with a flat chisel until bleeding points were reached, while on the right side multiple fine holes of 2 mm. diameter were drilled into the bone at a distance of 0·5 cm. from each other until bleeding occurred, care being taken not to injure the dura. Fourteen days later the chiselled portion was almost completely covered with healthy granulations, while on the opposite side granulations were only just beginning to appear out of the drill holes. As the child still complained of headache, and the bone between the holes was very tender, the remainder of the necrosed bone was removed with a chisel five days later. The spongiosa was found infiltrated with pus. After a somewhat stormy course, during which multiple small sequestra were extruded from the drilled side, the skull was eventually covered with granulations in about six weeks, and Thiersch's skin-grafting was performed. The child was discharged with the head finally covered with healthy skin about seven months after admission. In discussing the course of the case, Dr. Düttmann expresses the opinion that the trypaflavine was a contributing cause of the extensive necrosis, and quotes observations that have been made to show the destruction of tissue caused by that substance. The experiment of treating part of the necrosed area with removal by chiselling and part with drilling holes is instructive. The operation of chiselling was easy to carry out and relatively without danger to the patient, and the result in this case was perfect, whereas on the drilled side the procedure was difficult, it took much longer, and there was great danger of boring through the skull and of injuring the dura. The granulations which grew in the drill holes appeared to block the exit of pus from the spongiosa, and convalescence was delayed by the frequent extrusion of sequestra. Dr. Düttmann strongly advises against the method of drilling.

PNEUMOCOCCAL MYELITIS.

In referring last week to the work of the Institut Pasteur on lesions of the nervous system, we called attention to the possibility that certain cases of myelitis might prove to be of infectious origin. In his inaugural thesis Dr. Moïse Zissu[1] considers pneumococcal myelitis, of which he has collected 19 examples from the literature, including two original cases observed in Dr. Lemierre's service at the Andral Hospital, Paris. As regards the ætiology, age plays an important part, for of the 19 cases 13 occurred in adults, three in children, two in adolescents, and one in an old man; 15 were in males and four in females. The attack of pneumonia was severe in the majority of cases. Like the other extra-pulmonary localisations of pneumococcal infection pneumococcal myelitis may precede the pneumonia, develop simultaneously with it, occur at the height of the disease, or first appear in convalescence several days after the crisis. No examples have hitherto been recorded of the occurrence of pneumococcal myelitis, apart from a pulmonary localisation of the infection. Dr. Zissu has drawn up the following classification of the clinical forms of pneumococcal myelitis: (1) Circumscribed lumbo-sacral myelitis, of which there is a mild and a severe form, characterised by paraplegia, sensory and sphincter disturbances, and loss or exaggeration of the tendon and cutaneous reflexes. (2) Disseminated myelitis, in which in addition to the above symptoms there is paralysis in the upper limbs. (3) Meningomyelitis, in which the symptoms of myelitis are associated with signs of meningeal irritation. (4) Poliomyelitis manifested by paralysis and muscular atrophy of the lower limbs. (5) Acute ascending paralysis with or without sensory and sphincter disturbances. (6) Diffuse chronic myelitis, with paresis of all four limbs, contractures, exaggeration of the reflexes and muscular atrophy. Pneumococcal myelitis, though a serious condition, is not so fatal as other forms of infective myelitis. Nine of the 19 cases recovered, and ten died after an illness ranging from five to 25 days.

TOMARKIN'S "ANTIMICROBUM."

Some rather remarkable statistics have recently been published in Italy[2] on the results of treatment of acute pneumonia by a chemical compound produced by Dr. Leandro Tomarkin. The therapeutical product obtained by chemical synthesis, and called "antimicrobum," has a definite composition which is indicated by the name amino-orthobenzoyl-sulpho-isoamylo-hydrocupro-nuclein-formate of soda, and is prepared in two forms, monobasic and bibasic. Both of these are in the form of a greyish-brown powder. The bibasic combination is readily soluble in cold water, sparingly so in alcohol, and insoluble in ether. It is decomposed at a temperature of 50° C., and when heated to 70° C. gives off irritating gases. The monobasic form is insoluble in cold water, ether, and alcohol, and only slightly soluble in warm water. It also decomposes at 70° C. Twenty-five cases of pneumonia, chiefly lobar, treated in the San-Spirito Hospital at Rome during March, April, and May by antimicrobum, gave a mortality of only 4 per cent., whereas 50 patients treated during the same period with the usual symptomatic treatment showed a mortality of 40 per cent. In other wards of the same hospital the mortality was 55 per cent. and 38 per cent. with the usual symptomatic treatment. All forms treated with antimicrobum therapy were favourably influenced by it. The cases included several of exceptional severity, some bilateral with effusion. Usually resolution, either by lysis or crisis, was rapid and the disease presented a very mild course in nearly all cases, complications being rare. The drug appears to have been well tolerated in all cases, and its effect is explained as a combination of antitoxic and anti-pyogenous action, causing a biological transformation of the products of bacterial scission (endotoxins) and decomposing the bacterial toxins by precipitating the nucleo-albumin and altering their physical and biochemical properties so as to render them easily eliminable. It has, moreover, a marked phagocytic action, causing hyperleucocytosis of preponderating mononuclear type, thus mobilising the defensive bodies of the organism. The action of the bibasic combination is mainly antitoxic, while that of the monobasic is specifically bactericidal. This circumstance determines special methods for its administration. Whenever the treatment of pneumonia is commenced early—viz., on the first or second day, when the general toxic symptoms are not as yet much developed —one gelatin capsule of the monobasic antimicrobum is given every two hours. After two days the bibasic combination is given until resolution takes place. Should the treatment be delayed to a later period when general toxic symptoms are manifest, treatment should begin by giving the bibasic combination for one day, followed by the monobasic during the second day, after which the former will be resumed for at least 8–10 days, diminishing the dose by one capsule daily. It would seem that, having regard to the greatly reduced mortality in the observations recorded, compared with other methods of treatment, antimicrobum Tomarkin may prove to be an efficacious remedy for pneumonia, and one simple to administer. Other observations will naturally be required to establish its claims, and arrangements have been made to secure a supply of the drug from Italy for use in the Italian Hospital in London. The results of treatment there will be watched with interest.

A REMARKABLE TERATOMA.

We have received from Mr. E. J. Harrison the report of an extraordinary case. He had obtained it from a paper printed in Russian, which had reprinted it from the *Novoe Vremya*, of Belgrade. The report lacks some of those details which would be supplied in a professional description. It is too long to reproduce here, but the essence of it is that a man of 22 had been troubled for nearly 20 years by an increasing swelling in the left side of his abdomen, and, on being operated upon by Prof. Kostitch, two fœtuses were removed by that surgeon from the swelling; one fœtus, 10 inches long, had a head with hair, short thick body, a left hand and a right leg, and possessed two teeth in its mouth; the other, half the size, was rather more incomplete.

There seems little doubt that the condition should be classed among the teratomata as a twin variety of a remarkably high stage of differentiation. Such growths are to be referred to abnormal development of sex-cells, are well known in the ovary, and not rare among tumours of the testis. The degree of developmental progress seems to be the extraordinary feature in this case. The sex of the possessor of a teratoma is of small importance, as the fact already mentioned about testicular tumours is enough to show. The development of the sex-cell is parthenogenetic in that there has not been any apparent syngamy, but a cell is not the less "fertile" because it develops parthenogenetically. It has been found that normal parthenogenesis, such as occurs in some of the crustacea, is autogamous, coming into operation as the result of self-fertilisation by the second polar globule. This is a secondary acquisition, but there can be little doubt that parthenogenesis, using the term in a wide sense, is a faculty inherent in the earliest and most primitive cells; it probably dies out, but it is frequently capable of being waked up before its decease. In this connexion there is an interesting possibility. Among vertebrates in general, at any rate above the cyclostomes, there seems to be a double production of gonocytes not immediately related to one another. The first formation occurs in association with the alimentary tract, and the gonocytes formed here migrate along the mesentery, to reach finally the genital ridges. Many of them disintegrate on the way, and many more seem to miss their goal, and settle down and die in other parts. The relatively few cells that reach the gonad lose their characters and, for the first time, begin to divide. At the same time, the epithelial cells covering the ridge begin to divide rapidly, thus giving rise to the cells of the second batch of gonocytes, among which are the scattered remnants of the first batch. What the difference is, if any, in the final destiny of these two groups of cells remains to be shown. Definite proof of the occurrence of two such batches of gonocytes in man and higher mammals is lacking, but certain observations point towards its truth.

The meaning of such a process is very obscure, but it seems likely that the cells of the first efflorescence are more primitive than the others, and it is at least permissible to speculate on the possibility of their possession of parthenogenetic potentialities. It may be remarked incidentally that they have been seen to exhibit some of the early nuclear phases of maturation-division before degenerating. If gonocytes of the first order are assumed to be more likely to retain parthenogenetic leanings than those of the second, it would seem to be suggested that teratomata might owe their origin most frequently to a gonocyte of the first batch that ought to have disappeared. Such a view, highly theoretical as it is, would at all events give some explanation of extra-genital teratomata, such as the Belgrade case seems to have been. In the absence of an expert report we cannot say where the seat of the tumour may have been, but we are not debarred from hazarding a guess, that it was associated with the original median mesentery or dorsal wall of the cœlomic cavity originally close to this.

KERATODERMA PUNCTATUM.

According to Dr. S. E. Sweitzer,[1] of Minneapolis, who recently reported a case at the forty-sixth annual meeting of the American Dermatological Association, keratoderma punctatum, or punctate hyperkeratosis, of the palms and soles is a rare condition, of which he has found only 18 examples on record. The earliest case appears to be that reported in 1879 by Davies-Colley, who described under the name of "disseminated clavus of hands and feet" a condition of hyperkeratotic lesions on the palms and soles, the lesions being very small and showing cupping or pitting in the centre. In making a diagnosis, clavus, psoriasis, porokeratosis Mibelli, and angiokeratoma must be excluded. The late Sir James Galloway pointed out that a punctate keratosis of the palms and soles might occur in lichen planus, arsenical keratosis, syphilis, keratosis follicularis, linear nævus, and in association with verrucæ planæ. The true keratoderma punctatum does not show a generalised hyperkeratosis, nor any erythema at the edges of the lesions. Several of the cases on record, like that described by Dr. Sweitzer, have a hereditary tendency. Dr. Sweitzer's case occurred in a woman, aged 33, in whom the condition had started in early childhood. The father and one brother were similarly affected. The skin over the general body surface was normal, only the palms and soles being affected. The lesions, which were small, horny, and papular and of a light-yellow colour, and showed slight pitting, were distributed over the thenar eminences, the palms, and palmar surface of the fingers. The soles showed a few scattered lesions on the big toe and ball of the foot. The arch of the foot was comparatively free, except towards the heel, which was studded with small horny yellowish lesions, most of which showed a central depression. Microscopical examination of a punctate lesion removed with a biopsy punch showed that the chief changes were in the horny layer, which was greatly increased in a circumscribed manner without any change in structure. There was no inflammatory infiltration in the corium.

QUOTA OF DOCTORS IN SOUTH AFRICA.

CONSIDERABLE resentment appears to have been caused in medical circles on the Witwatersrand by the appearance in the *Rand Daily Mail* of Nov. 15th of an interview with "a well-known medical man," who is alleged to have said that South Africa could do with five times the number of doctors she has at present—that is, with 10,000 instead of under 2000. In the dorps and villages, so it ran, wealthy practices are crying out for medical assistance, and many places which to-day carry only one medical practitioner could easily support three or four more, and provide them with a fair livelihood. The Witwatersrand Branch of the British Medical Association, whose regular monthly meeting happened to be held on the very day the article was published, took immediate action to prevent these statements gaining credence by passing the following resolution:—

> That the statement attributed to a "leading medical man" published in the *Rand Daily Mail* on Nov. 15th to the effect that South Africa can find remunerative openings for 8000 medical practitioners, is incorrect, misleading, and calculated to do a great deal of harm by encouraging immigration to this country of medical men from overseas, and by encouraging an unnecessarily large number of men in this country to take up the study of medicine. It is the opinion of this branch that South Africa is not at present in a position adequately to support more than the approximately 1800 practitioners it already has, and that, as a matter of fact, many well qualified and competent medical men in South Africa even now find great difficulty in making both ends meet.

A few days after this a letter, published by the journal which first gave prominence to the subject, effectually disposed of any arguments supporting a theory of shortage of doctors in South Africa. This letter was signed by Dr. A. J. Orenstein, who is entitled to speak with some authority on the medical situation in South Africa. He points out that there are in South Africa some 1,700,000 whites and 6,500,000 natives. Most of the natives live in kraals and are semi-savage. Their earning power—expressed in cash—is very low. Their ability to pay for medical attendance is practically nil. The ability of the native population to support medical men in private practice can be considered as negligible. Native medical services have to be provided by the Government, and it will be long before any government is able to provide a greatly increased medical service for natives. The European population of South Africa practically unaided now supports some 1800 practitioners, either directly or indirectly. There is to-day in South Africa one medical man per 1000 Europeans, compared with England 1 to 1000; Germany 1 to 1940; Austria 1 to 2120; France 1 to 2834 (pre-war figures). Dr. Orenstein's considered view amounts clearly to this: that for many years to come South Africa will not be in a position to support more than approximately the 1800 medical men it has now, and medical schools and parents would do well to bear this fact in mind. People in large centres of population are apt to be blinded to the true condition of affairs by observing a few prosperous medical men in their midst. The bulk of the medical men in South Africa earn but a bare living. An advertisement in that country for a full-time medical man at a salary of a thousand or thereabouts brings scores of eager applicants. Would that be the case, asks Dr. Orenstein, if this country had only one-quarter the medical men it actually requires?

We sympathise with the anxiety of medical men in South Africa to prevent further congestion in a professional community which already meets the effective demand, but when we read carefully the article which caused this anxiety we are inclined to doubt whether it is likely to mislead the public. More than two-thirds of its contents are filled with eulogies of the medical school of the Witwatersrand University, and reads more like a patriotic appeal for support of this school than a serious attempt to induce British medical men to come to South Africa in search of an easy livelihood. At any rate, the prompt disclaimers from authoritative sources carry conviction and will prevent men from going to South Africa in the hope of readily establishing a lucrative practice.

THE ANNUAL DINNER OF THE ROYAL SOCIETY OF MEDICINE.

OVER 500 Fellows and Members of the Royal Society of Medicine, out of a roll of 4000 or so, dined together at the Hotel Victoria, Northumberland-avenue, on Tuesday, Dec. 11th. Sir William Hale-White was in the chair, and opportunity was taken to welcome H.R.H. the Prince of Wales as newly elected Honorary Fellow of the Society. Vice-chairmen were the principal office-bearers of the Society along with the representatives of various Sections—namely: Mr. Douglas Gabell (Odontology), Dr. R. J. Reece (Epidemiology), Mr. C. A. R. Nitch (Surgery), Dr. Farquhar Buzzard (Hon. Treas.), Dr. A. M. H. Gray (Hon. Sec.), Sir John MacAlister (Secretary), Mr. W. Girling Ball (Hon. Sec.), Mr. C. H. Fagge (Hon. Treas.), Dr. Robert Hutchison (Medicine), Dr. Cuthbert Lockyer (Obstetrics), Mr. H. J. Banks-Davis (Laryngology), and Sir Layton Blenkinsop (Comparative Medicine). The official guests were the Archbishop of Canterbury, Viscount Haldane, and the Minister of Health. After the loyal toasts had been honoured, the Prince proposed the Royal Society of Medicine. Following the advice of Sir Benjamin Brodie "to abstain from medical politics" he spoke of the merciless law of survival of the fittest in its application to learned bodies and gracefully acknowledged the privilege of belonging to a Society with such an old and honourable tradition. He paid a tribute to the energy and perseverance of Sir John MacAlister in building up the constituent units of the Society into a united whole. Sir William Hale-White, in responding, enumerated the evidences of active life in the Society, the library of which now numbered 120,000 volumes and sent out yearly 3000 parcels of books to Fellows in the country or abroad. The collection of over 4000 medical prints, remounted and catalogued by Dr. Arnold Chaplin, would, he said, soon be accessible for reference. In two directions new ground was being broken: combined meetings of allied Sections and meetings of the whole Society were being arranged for the discussion of topics of more than sectional interest; and a new and active Section of Comparative Medicine had been founded under the presidency of Sir Clifford Allbutt. The toast of "The Guests" was proposed in a racy speech by Dr. Herbert Williamson, to which Lord Haldane and Sir William Joynson-Hicks responded. The latter voiced his satisfaction at the fact that medicine was broadening its scope to take in the diseases of animals. He hoped that help might speedily be given him to deal with the problem of foot-and-mouth disease. The country was paying £70,000 a day for the slaughter of affected animals and a Cabinet Committee had been appointed that very day to consider the very serious situation. A programme of music was provided by Mons. Dore's orchestra, and the success of the evening was largely ascribed to the arrangements made by Mr. Girling Ball.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XLIX.—THE TREATMENT OF PROLAPSE.

PROLAPSE is a comprehensive term which covers a variety of lesions differing in their ætiology and pathology. Before its treatment is attempted the practitioner must satisfy himself by careful local examination, vaginal, and also rectal and vesical if necessary, not only that he is actually dealing with a case of prolapse, but which of the following conditions are present:—

(*a*) The anterior wall of the vagina may have prolapsed with bladder (cystocele), or urethra (urethrocele), or both, the uterus itself occupying its normal position. The displacement implies stretching or atrophy of the muscular sheet and fascia supporting the bladder and vaginal wall.

(*b*) The uterus may be retroverted and displaced from above downwards on expulsive effort, owing to relaxation of its parametric supports. This displacement is usually complicated by cystocele. It is important to distinguish between a uterus which is merely retroverted and a uterus which is retroverted and also descends.

(*c*) The vagina may be completely everted, a further stage of (*b*). Complete uterine prolapse or "procidentia" is a hernia through the pelvic floor, facilitated by stretching or atrophy of the muscle in the uterine parametria. The sac of the hernia is constituted by the vaginal walls and the contents by the uterus and its appendages. The anterior vaginal wall contains the prolapsed bladder. The posterior wall frequently involves prolongation and descent of Douglas's pouch. The rectum is not prolapsed.

(*d*) The cervix uteri may be elongated, and hypertrophic, either in its vaginal or supra-vaginal portions or both, without any descent of the uterine body. Elongation of the supra-vaginal portion inverts the vagina from above.

(*e*) The posterior vaginal wall may be adherent to the anterior rectal wall, and prolapsed with a pouch of the anal canal as a "rectocele." The uterus itself is not involved.

Various combinations of these pathological lesions co-exist. Backward displacement of the uterus does not signify prolapse unless it is associated with cystocele and descent of the organ on expulsive effort. In nulliparæ practically the only type of prolapse seen is inversion of the vagina from above, with hypertrophic elongation of the supra-vaginal cervix. In some women with very lax tissues, a general downward displacement of the pelvic floor occurs without any dislocation of its individual units. This appears as a general bulging of the perineum upon downward pressure.

The therapeutics of genital prolapse are best considered under the following sections: (1) Prophylactic, (2) operative, and (3) palliative measures.

Prophylactic Treatment.—The great majority of cases of prolapse are attributable to, and the result of, factors intimately bound up with pregnancy and labour. In the first place, pregnancy too often and too frequently repeated is a fertile source of laxity of the parametrium. Involution is not only confined to the uterus, but also involves the muscular fibres of the pelvic parametric tissues. If involution is excessive and the involuntary muscle of the parametria is replaced by fat or fibrous tissue, tone is lost, and the uterus, whether large or small, tends to prolapse. A heavy bulky uterus dragging upon such weakened supports naturally tends to descend more rapidly, although a small organ is not immune. Similarly a constantly distended bladder under the same conditions produces further dislocation and the formation of a cystocele. Numerous pregnancies and the resumption of hard manual work account for much of the prolapse met with in hospital and panel practice.

Another factor is the application of forceps before cervical dilatation is complete. A great deal has recently been said and thought about the use and abuse of the obstetric forceps, and it is not necessary here to labour the point. All that need be said is that if "high" forceps are applied and traction exerted before the passages are sufficiently dilated, so that the uterus as well as the fœtal head is dragged down, that uterus will surely descend in later years. Subsequent involution can never restore to normal a parametrium artificially stretched to such an extent. The tissues of individuals vary considerably. Some are congenitally strong and withstand trauma both natural and artificial; others are congenitally weak and cannot resist even slight stress; others tear easily and do not stretch, and yet others stretch and do not tear. Inasmuch as it is impossible to foretell the type of masonry with which the human frame is constructed, the obstetrician should, whenever possible, apply patience before forceps.

Finally, the influence of sepsis must not be forgotten. An infected perineal laceration, even if the tear subsequently heals satisfactorily, may lead to adhesion between the walls of the vaginal and anal canals. This is the prime factor, if not the only one, in the production of rectocele. The prevention of rectocele therefore lies in the immediate and accurate suture of perineal tears, and the adoption of antiseptic measures. It is impossible to suture a perineum accurately with the patient lying on her left side. She should be placed in the lithotomy position and the laceration thoroughly exposed. The surface is then cleansed, blood-clot removed, and the vaginal edges approximated. Buried sutures are used to draw together the deep perineal tissues, and so form a good pad of tissue between the vaginal and anal canals. This is the important factor in the prevention of subsequent rectocele. Finally, the skin edges of the perineum are brought together, and the whole thoroughly dusted with some antiseptic powder. A shot in the dark with through-and-through silkworm-gut sutures introduced with the patient in the left lateral position is a rough-and-ready method which may or may not produce an "anatomical" perineum. It certainly does not produce a "physiological" perineum, which permits of the rectal wall sliding upon the vagina during defæcation. The lesson to learn from these various observations is that indifferent midwifery to-day may be responsible for the production of prolapse ten years hence.

Operative Treatment.—Within recent years the tendency has been to relegate more and more the treatment of genital prolapse to the surgeon. There is no doubt that the results of modern surgical technique in this connexion, both immediate and remote, are good. Since the anatomy of the pelvic floor and the supporting structures of the female pelvic organs have been better understood, there has been a reversion from the abdominal to the vaginal route. To-day it is regarded as unnecessary and undesirable to attach a uterus that prolapses to the anterior abdominal wall. It can be cured with less risk to the patient by a vaginal operation. Also it is unnecessary and actually wrong to remove a prolapsed uterus "in toto" unless it is also the seat of some disease calling for hysterectomy. The aim of modern plastic vaginal surgery is to build up and consolidate the atrophied or stretched parametrium, and to maintain the prolapsed viscera in their normal positions. In other words treatment is conservative, and aims at a *restitutio ad integrum* rather than mutilation or the substitution of one disability for another. The older colporrhaphies failed because they were incomplete. The supporting structures of the pelvic viscera were not understood, and false reliance was placed upon the vaginal walls rather than on the underlying parametria and pelvic floor. By adopting the technique described by Fothergill, the "buttress" method of Blair Bell, or the extensive colpo-perineorrhaphy of Archibald Donald, or by a combination of these methods, the surgeon can confidently approach any degree or variety of prolapse.

Experience has proved the value of these methods in patients in whom other pregnancies are anticipated as well as in elderly women. Modern technique has quite replaced such methods of treating prolapse as those described by Le Fort and Schauta operations, which cure by substituting a deformity and which, moreover, are associated with a definite mortality.

Palliative treatment occupies a definite place in the treatment of prolapse. A well-fitting pessary relieves many a patient from her symptoms, and for women who fear or refuse operation, or for whom the latter involves some risk, such treatment is indicated. Furthermore, it is impossible with the hospital accommodation of to-day to deal surgically with all the material presented. It is important to appreciate what a pessary will and will not do. It is useless, for example, to expect relief from a pessary if the lesion consists of hypertrophic elongation of the cervix. Similarly, a pessary is of little or no avail in the treatment of rectocele, advanced cystocele, or complete procidentia. Palliative treatment should be reserved for: (1) Slight or moderate degrees of cystocele; (2) retroversion of the uterus without descent, if it is the cause of symptoms; (3) retroversion of the uterus with descent of moderate degrees; (4) prolapse of the vaginal walls during pregnancy. The treatment of severe and advanced degrees of prolapse calling for much scaffolding in the form of very large pessaries is best conducted by surgical measures.

The mechanical devices in use to-day may be classified under the following headings: (1) Self-retaining "ring" pessaries of the solid rubber, "watch-spring," or rigid vulcanite or celluloid types; (2) self-retaining "oblong" pessaries of the "Hodge" or "Albert Smith" types; (3) self-retaining pessaries of the Simpson "shelf" variety; (4) rubber "ball" pessaries; (5) "cup and stem" pessaries with outside straps; (6) perineal pads. Rubber instruments have the great disadvantage of producing irritating discharges, and require constant attention. Probably the solid rubber ring is the best all-round instrument It is comfortable and easily introduced, but the patient should be examined every two or three months, and must douche at least thrice weekly with some unirritating solution such as normal saline. "Watch-spring" pessaries are dangerous, owing to possible deterioration of the rubber covering. Rigid instruments have the disadvantage of producing vaginal ulceration if too much tension is exerted by their size or atrophy of the vaginal walls in old age. The choice between a "ring" and "Hodge" depends upon the variety of prolapse and the direction in which it is desired to produce tension of the vaginal walls. For uncomplicated cystocele a "Hodge" is often efficacious, without having recourse to either a "cradle" or "ring." In cases of inversion of the vagina from above, it will be obvious that tension must be exerted in all diameters, and therefore a "ring" must be used. Simpson's "shelf" I regard as an abomination. Its only merit is that it is efficacious in keeping a prolapsed uterus in position. Its introduction and extraction can be so painful and distasteful to the patient that a woman tends to leave the instrument in situ until its presence causes pressure symptoms. Museums contain many "shelf" pessaries, which have ulcerated into either bladder or rectum, and which have required removal with bone forceps. Collapsible "ball" pessaries and "cup and stem" instruments are sometimes useful in affording relief to women with severe procidentia where surgical treatment is refused or contra-indicated. Their disadvantages are obvious, and in all cases patients should be instructed not only how to remove them at night, but also how to keep them clean. In those cases where the pelvic floor as a whole descends any pessary is, of course, useless. The only treatment that can be given is support by a perineal pad, apart from the relief afforded by certain douches and local baths at the various spas.

In conclusion, it must be remembered that once pessary treatment is instituted, a woman in nine cases out of ten is condemned to wear an instrument all her life, unless she submits to surgical treatment. Frequently it is necessary to employ larger and larger pessaries, and in the end the patient discovers that she has not avoided but only put off the evil day, and eventually is faced with either operation or the discomforts of an instrument with straps.

RADIO-ACTIVITY IN MEDICINE.

BY SIDNEY RUSS, D.SC., F.INST.P.,
JOEL PROFESSOR OF PHYSICS, MIDDLESEX HOSPITAL.

THERE is so much difference of thought and practice about the indications, scope, and methods of application of radio-active substances in medicine that a review of the limited knowledge at our disposal may be of use in clearing the ground. The use of radio-active substances for medical purposes followed soon after the discovery and preparation of radio-active bodies. The home of the discovery in this case was France, where Henri Becquerel discovered that uranium spontaneously emits rays. It has been suggested by Regaud that the therapy in which radio-active substances are used should be known by the name Curie-therapie, thus honouring still further a name which will always be associated with a discovery of far-reaching importance, that of radium, a substance about two million times as active as uranium.

For the physicist there are two essential conditions that must be satisfied before a substance is admitted into the circle of radio-activity. One is that it must spontaneously emit rays, and the other that it must no less spontaneously change into some other substance. The rays from a few radio-active bodies have not been isolated; pending this they are called "rayless." The word spontaneous has especial weight in this connexion, for while there are many ways known by which substances may be *made* to emit rays, there is no chemical method by which the atoms of any element may be changed into another. This is the natural course of events in radio-active elements, of which there are now about 40 known. Of late years a physical method has been developed by Rutherford which does in certain instances appear to dislodge a fragment from the very interior (or nucleus) of the atom; this fragment is a hydrogen atom, which comes out at a great speed, and so we may look upon a stream of these atoms as a form of radiation strictly analogous to the alpha rays which come out at great speed from many radio-active bodies. It must be admitted that on a very restricted scale bodies can be made radio-active, but it is a very remote possibility that the natural product will ever have to give way to the manufactured article.

Local and General Action.

None of the effects which the rays from radium have upon man and the lower animals have received so little attention as the physiological ones. The subject is one which simply cries out for investigation, but the literature on the subject reveals how little is known. Yet the general effects of these radiations upon the body are profound and significant—profound enough to cause death from over-exposure, and significant enough to revolutionise in the future many methods of treatment which are now carried out without the benefit of exact knowledge. It may be regarded as almost certain that, although radium is applied quite locally, some general action always supervenes.

Two experimental facts may be mentioned which show that the general action upon the body may be completely reversed in character according to the degree of irradiation. If a piece of a tumour which has been exposed to a lethal dose is inoculated into an animal, this animal becomes immune to implantation of the same sort of tumour; when an immune condition has been set up in this way it is a very stable state and in most cases lasts the animal's life-time. If such animals are then given a heavy dose of radiation, followed by a tumour implantation, the result is often that the tumour will grow temporarily. On the other hand, if we take some animals which are normally susceptible to these tumours and put them on a course of treatment which consists of very small doses of radiation spread over several weeks or months, and then inoculate tumour into them, the result is that the tumour will not grow so readily as in the normal animal.

Of the purely local action of the rays it will perhaps be enough to say here that detailed histological studies have shown that definite changes occur in the state and structure of cells after irradiation, and that in many cases the degeneration is enough to cause the disappearance of the cells. Other changes appear to be of a much more complicated character, and the early studies of Dominici showed the significant part which the normal and apparently unaffected tissues of the host play in what may be called the sequel to irradiation.

The Criterion of Medical Utility.

Of the two conditions necessary before a body is recognised as radio-active, the important one in connexion with medicine is the emission of rays, the spontaneous change of the atoms of one element into the atoms of another having no medical import. From the medical standpoint the importance of a radio-active body depends on the kind and quantity of the rays it gives out. There are three kinds of rays given out by radio-active substances and they were called alpha, beta, and gamma rays before their true nature was recognised. Some substances emit only one variety, others two and some, as a result of their atomic instability, emit all three. The order of medical utility of these rays is probably in the reverse order from that in which they are mentioned. Gamma rays are transverse vibrations of the ether and have the smallest wave-length known; the shortest of them is about a quarter of the wave-length of the shortest X rays which can be produced at the present day. It is not likely that electro-technicians will be attracted to the problem of producing such very short wave-lengths; their production is more economically left to Nature's workshop. We may mention that some of the gamma rays from radio-active substances have the same wave-length as very hard X rays, and their identity has been firmly established. It must not be concluded that gamma rays of the shortest wave-length have the same physiological actions as X rays, for experiments have shown that X rays of different wave-lengths produce different effects upon animal tissues even though the same amount of energy is expended.

Next in importance come the beta rays, electrons of a speed only a little less than that of light, called rays before their identity with the cathode stream of the Crookes tube was disclosed; and here again we may remark on the fact that the beta rays leave the atoms with a considerably greater speed than can be artificially imposed upon electrons, as in an X ray tube. Though travelling at high speed the beta rays have not much penetrating power; half an inch of tissue would practically quench them. They give rise to an intense local action when an unfiltered source of radium is placed in the body, but this can be avoided by the use of silver or platinum screens.

The alpha rays are atoms of helium; they are very high-speed gas particles which, however, have so little penetrating power that a sheet of notepaper can stop them; their medical use is very limited, though where they do act their effect may be very intense. When judging the medical utility of radio-active substances in a general way the two things to consider are—does it give out gamma and beta rays and does it give them in large quantities? Radium is without doubt the most extensively used radio-active substance in medicine and yet it gives out neither gamma nor beta rays. To explain this paradox we must here make a digression.

The Emanation.

One of the most surprising discoveries in radio-activity was that a "something" was given off by some of these substances which resembled a gas. When Rutherford discovered this was the case with thorium he had natural hesitation in calling it a gas, and in fact he called it an emanation. When Dorn followed up this discovery by showing that radium also liberated a gas, this was called radium emanation. Further researches showed that these emanations were true gases in the ordinary meaning of the word, but they were also radio-active, which distinguished them from the other gases known to the chemist. There is one other emanation known called actinium emanation, but radium emanation is the only one of medical utility. Ramsay suggested that this should be called niton (the shining one), but the original name has generally been maintained, and it does not appear to be too big a strain on general courtesy that the christening name suggested by a discoverer should be accepted by others.[1] The emanation is spontaneously produced from radium. The radium gets used up by this act of production, but only very slowly; an ounce would get reduced to half an ounce, a gramme to half a gramme, a grain to half a grain in about 2000 years. It is to be noticed that whatever quantity may be taken to start with, half of it always gets used up in the same time. This time is called the time-period and the same sort of process runs through all the radio-active bodies. They all have different time-periods and in all cases this term is used to indicate the time taken for one half the quantity present to change into something else. The emanation half vanishes in 3·85 days, it goes on half-vanishing every additional 3·85 days, so that in about a month there will be less than 1 per cent. of what there was to begin with. As it vanishes it emits alpha rays and changes into a substance known as the active deposit.

The Active Deposit.

The active deposit is so-called because it sticks to the surface of things; it is no longer gaseous but solid. It is really a very complicated mixture, the details of which cannot here be dealt with; the important thing about it for our present purpose is that it emits gamma and beta rays in large quantities. Here, then, is the explanation of the paradox, for though radium itself emits none of these rays, its products do. If radium is sealed up in a tube, it at once begins to produce the emanation; this in turn produces the active deposit, which gives the main radiation. Since radium is, practically speaking, a permanent radio-active body, the yield of rays goes on indefinitely and the more radium there is in the tube, the more rays we get from it.

It is, of course, quite a different matter if the emanation is pumped off from the radium and collected in a tube. To do this some radium chloride or bromide is dissolved in hydrochloric or hydrobromic acid and run into a flask which is then sealed on to a mercury pump. As the emanation is produced from the parent substance it is pumped off, purified of any contaminating gases and condensed by means of liquid air into a tube or other device. The volume of pure emanation which one could collect from so large a quantity as 1 gram of radium would not be so much as a cubic millimetre. Hence it is possible to get a very intense radio-active source by condensing the emanation into a minute glass tube; in this case the active deposit will in due course be produced and we shall get the appropriate amount of gamma and beta rays, but it will gradually decline in strength according to the half-value rule mentioned above. Therefore, when the emanation is used medically there is a little more trouble in specifying the actual strength of the source that is used. In this country we generally reckon the

---

[1] An International Committee on Chemical Elements, 1923, has recently suggested that radium emanation should be called radon.

average strength of the tube during the time it is used. The French school has adopted a quantity which depends on the number of "millicuries détruits," and although this method has not yet been generally accepted there is something to be said for its adoption. The main idea of the method is based upon the argument that the effective amount of radiation obtained from a tube is proportional to the amount of emanation that is vanishing into the active deposit, and, as the emanation unit is the curie or its fraction the millicurie, the number of these "millicuries détruits" is an indirect measure of the effective radiation employed.

Radio-active Substances other than Radium.

The only substance which emits gamma and beta rays in quantity comparable with that of radium and its products is mesothorium. The gamma rays emitted by this substance are actually a little, but not much, more penetrating than those from radium, and the preparations of mesothorium are sold on the basis of radium standards. A tube of 50 mg. means a tube which gives the same amount of gamma rays as a tube containing 50 mg. of radium, and so on. The price is about one-half that of radium, mainly owing to the fact that the preparations are not permanent; they diminish in strength much more quickly than radium does and so the owner is threatened with severe capital depreciation. The preparations get a little stronger after they have been kept for a time and then they half-vanish in about ten years.

Points in Dosage.

The medical and surgical conditions for which radio-active substances are used include certain forms of malignant disease, some gynæcological conditions, and many varieties of skin affections. There is a large mass of physical data available about the rays and their properties, but it is still difficult to formulate a scheme for the use of the weapon on a strictly quantitative basis. Until such a basis is established it will remain difficult for anyone to describe his methods of using radium in such a way that other people may benefit by his experience. This obstacle cannot be overlooked and there are no successful short cuts to its solution. A typical instance of the short cut is the introduction of the term milligramme hours; this figure is obtained by multiplying the number of milligrammes of radium (or of radium salt) by the number of hours for which it is used. Nothing could be more misleading than such a term, for it is of vital importance to know the actual weight used and the time during which it is applied, and these are frequently not stated by writers. No physician would expect to be taken seriously if he specified the dose of the drug which he had used by such a term as minim months. For surgical use radium is generally sealed in platinum or other metal tubes suitable in size for the amount of radium used, and the statement of dosage must begin with a description of the tube, its length, diameter, thickness of metal, and the quantity of radium it contains, with the further information whether any additional screen was employed. The next step is where the difficulties begin; if three or four of such tubes are inserted into a growth, how can information be set down which will be quantitatively useful? Perhaps the most (and the least) that can be done is to state approximately the size of the growth in question, specify the distances separating the tubes and how far beneath the skin they are placed, and for how long they are left in position. If this is supplemented by drawings to scale, a very valuable amount of information may be got, quite enough in fact for the description of a technique that others may perhaps wish to follow. Something has to be left to the individual even with all this information before him. He has to bear in mind and attempt to visualise the variations in the strength of the radiations from point to point in the tissues, for it is impossible to get uniformity by the means described.

Selective Action.

Were it not for the fact that the rays in passing through the tissues of the body affect some of them more than others there would not be much place for radium-therapy. This selective action lies at the root of the matter, and it has been abundantly proved that in their reaction to radium rays animal tissues form a long series ranging from those which are extremely vulnerable to those which are very insusceptible. If for practical purposes of illustration we fix upon the skin as a type of tissue which is vulnerable to the rays to a medium extent, then on the side of greater vulnerability we should have to put some of the blood cells, cells of the ovary and testicle, and a few varieties of malignant cells, while at the other end of the list, as instances of tissues more resistant to the rays, we should place most varieties of malignant cells, muscle, nerve-tissue, &c.

A great deal of practical interest centres round the degree of selective action that the rays exert upon malignant and normal tissues, for it is more than probable that the series of events following irradiation is determined somewhat by the interplay of forces between them. We may in fact say that the sequel to tumour irradiation depends not only on the dose which it has received, but on the nature and extent of the reaction of the normal tissues of the host. Following the exposure of several varieties of the lower animals to the gamma rays from a large quantity of radium, Lazarus-Barlow has made a detailed study of the degree of selective action exhibited by the normal tissues. His main results are embodied in the Medical Research Council's Special Report Series, No. 62 (1922).

Lethal Action.

The chief aim in using radium in the treatment of malignant disease is to kill the malignant cells with as little damage to the healthy cells of the body as possible. The dose that will just be sufficient to prevent any further growth of cancer cells is called the lethal dose. So it follows that, if the parts of a tumour which actually get the least amount of radiation receive a lethal dose, then, in many cases, other parts receive much more than the lethal dose; in some instances the difference in the amount of radiation may be so great that actual necrosis of the tissue occurs. This is not generally considered good therapy. If less than the lethal dose is given the growth of the cells may temporarily be arrested, but almost inevitably the time comes when they will again become actively dividing and growing cells.

It is a comparatively easy matter experimentally to slow up animal tumours by doses of radiation which are less than a lethal dose, so that they grow at a half, a third, a quarter, or an even smaller fraction of the normal rate of the tumour, although there may still be no recognisable histological change in the cells. If a very small dose is given the question arises as to whether the tumour cells would grow quicker than the normal rate. It has been observed under these conditions that the tumour does grow a little quicker than usual, but it is a very difficult thing to be sure of. The whole question of the stimulating action of radiation is of great importance.

Stimulating Action of Radiation.

Perhaps no aspect of radiation therapy has met with such controversy as that generally included under the term "stimulating action." It is pretty clear that much of this controversy might have been avoided if the single term "stimulation" had not been used to cover a whole lot of phenomena which had little in common with each other. But the term has been dragged in to express equally well what happens if a tumour happens to grow faster after radiation treatment and the earlier hatching out of a batch of irradiated larvæ than the batch of controls. The word has been used with too much latitude, and it seems that as the action of radiation upon cell life yields more and more to experimental treatment, we want more explicit terms to describe the general features of the processes which are being studied. One does not, in fact, have to select such widely different examples as has been done in order to illustrate this point. The necessity is felt even if we restrict our attention to the irradiation of a tumour, for it seems that there are at least two possible ways in which the tumour, being apparently stimulated, might increase (instead of decrease) in size. If a tumour is septic the effect of a moderately big dose of radiation may be that the tumour grows faster than before; it is said to be stimulated. The general argument here could be that the normal tissues are already lowered in tone by the sepsis and, further, by the radiation, and although the tumour cells may have received a dose which under ordinary circumstances would slow them up, the normal tissue factor more than counter-balances this, and the tumour goes ahead. If this is to be considered stimulation, then it must clearly be distinguished from the possible increased rate of growth of individual cancer cells when they received 1 or 2 per cent. of the lethal dose. The importance of studying the normal tissue reaction of the host in radiological problems has not, indeed, received sufficient attention from physiologists.

Radio-activity and Spa Treatment.

It has been pointed out how little is yet known of the general effect even of irradiation carried out by applying tubes of radium or emanation to the surface of the body. What, if any, action is likely to be exerted by radio-active substances as they occur in natural waters remains highly speculative. A natural water rich in radium is still to be looked upon as an extremely weak concentration of radio-active material. It is not generally realised that there are few samples of water which do not show the presence of radium in minute quantities. When J. J. Thomson found radium in the tap-water at Cambridge many years ago this led to a very exhaustive series of measurements of the radium content of spring and river waters and the sea all over the world. It turns out to be, at one and the same time, one of the scarcest and yet one of the most far-flung elements. Some of the springs were found to contain a relatively large amount, not surprising if they are looked upon as collectors, often over large areas. Many spas published accounts of the radium content of their water, and there was a little delicate rivalry about some of the figures. Questions were raised about the possible part that this radium might all the time be playing in the treatment at these centres; suggestions, not perhaps amounting to claims, were made that such quantities of radium probably had a good deal to do with the efficacy of the waters. Others were not unmindful of the high content of other significant salts with which these waters were loaded, and the challenge was made that proof of the radium theory would be easy to establish if it could be shown that distilled water rendered radio-active to the same degree was just as efficacious as that of the waters of the spa itself. I am not aware that the challenge has ever been taken up and the true scientific foundation for spa therapy is still to seek.

MEDICINE AND THE LAW.

A JUDGE UPON EVIDENCE OF INSANITY.

TWO cases were referred to in THE LANCET of Dec. 1st, p. 1206, both tried at the Central Criminal Court, in one of which Judge Atherley Jones bound over an accused to come up for judgment if called upon in order that he might go into an institution, and in the other of which Sir Ernest Wild passed a "hard sharp sentence" in order to "teach" a young woman, who had certainly performed many criminal acts, presumably to live an honest life. In both of the above cases there was medical evidence from prisons where the accused had been confined that they were not certifiably insane but mentally defective. Since their cases were disposed of Mr. Justice Avory has had before him twice a man named Iggulden, and has sentenced him to death for the murder of a woman whom he undoubtedly killed. Iggulden cut the throat of Ethel Eliza Ireland in a taxi-cab, and at once drove to a police-station, told the police what he had done, and gave himself up. Before he was arraigned at the Central Criminal Court, counsel instructed on his behalf submitted that he was not fit to plead or to instruct counsel as to his defence. On this issue Dr. W. N. East, who had him under his charge at Brixton prison, gave a positive opinion that though the prisoner might be able to follow the proceedings, he was not fit to instruct counsel. Dr. East mentioned that Iggulden suffered from delusions, but that he would say nothing about them for fear of being brought in insane. Mr. Justice Avory, addressing the jury, after questioning Dr. East, directed them to bear in mind that "justice had to be administered according to law and not according to the view of medical men." Dr. East had expressed the opinion that the prisoner was able to follow the proceedings. If he could do that, his Lordship said, and if he understood what the witnesses said against him, it was for the jury to judge whether he was not able also to give instructions for his defence. His lordship said that he had observed that the prisoner took a lively and apparently intelligent interest in the proceedings then going on. If the jury were not satisfied that he was insane so as not to be fit to plead, the case would proceed. The jury found that the prisoner was fit to take his trial, and on the next day he pleaded "not guilty," and his trial took place, with the result that he was convicted of murder and sentenced to death. After this the jury recommended the prisoner to mercy, and were told that the recommendation would be duly forwarded to the authorities. For the defence evidence as to the prisoner's mental state had been given, witnesses, who proved that his grandmother on his mother's side was insane and an aunt and a cousin were idiots from birth, being preceded by Dr. East, who expressed the opinion that the prisoner was insane, and did not know that what he was doing was wrong when he killed his victim. Dr. T. B. Hyslop gave evidence to the same effect, and was emphatic in saying that Iggulden had no wish to escape death, and only desired to find a way out of life. This was with reference to a point which evidently weighed with Mr. Justice Avory, and to which he made reference in his summing up, advising the jury to consider that the prisoner knew that the medical men were examining whether he was sane or insane, and to judge whether in those circumstances, with a prospect of escaping death by being found insane, his statements could be relied upon. No doubt more will be heard of the case, and if the Court of Criminal Appeal uphold Mr. Justice Avory's summing up the Home Office authorities will have to consider the question of his sanity before the man can be executed. With regard to Mr. Justice Avory's statement above, that in cases of this kind justice has to be administered according to the law, none will find fault; when he adds that it is not to be done "according to the view of medical men" the question is suggested, "Then why call medical men as witnesses?" Is their evidence to be accepted only when the Judge agrees with it? And is the jury, even with the aid of the Judge, better able to ascertain the mental condition of a prisoner in the dock than medical men with training and experience to qualify them, who are able to examine him and converse with him? A prisoner, sane or insane, admittedly may try to practise deception, but the expert, it is submitted, is vastly better able to judge this than the layman.

ROYAL MEDICAL BENEVOLENT FUND.—A ball in aid of this fund will be held at the Kensington Town Hall on Feb. 5th, 1924, under the auspices of the British Medical Association (Kensington Division). Tickets 1 guinea each, or six for 5 guineas, can be obtained from the Hon. Secretary, Dr. Howard Stratford, 20, Upper Phillimore-place, Kensington, London S.W.

PARIS.

(From our own Correspondent.)

A Proposed Medical Council.

After a long inquiry judgment is about to be passed concerning the scandal of the "medical coupons," on which I commented in my letter of June 16th. Further convictions have been lodged recently in various towns of France and particularly in Paris. It will be remembered that certain officials, doctors, and pharmacists were found to have tampered to their own considerable profit with the vouchers honoured by the State in connexion with the free medical and pharmaceutical treatment of pensioners. The scandal has evoked a feeling of disgust among the medical profession generally, which has been shared by the public, but the public is apt to forget that among the 22,000 doctors practising in France a small proportion only are black sheep whose shortcomings have been emphasised and exaggerated by copy-hunting journalists. Nevertheless it cannot be denied that, besides the scandal of the medical coupons, there have been too many shady practices indulged in for greed of gain; convictions have been lodged for traffic in narcotics and for attempts on the part of proprietors of questionable cliniques to circumvent the law. The time was ripe for reconstruction and the first move was taken by the doctors' syndicate of Toulouse, which, inspired by Dr. Aversenq, proposed to create an Ordre des Médecins which would take on a disciplinary function similar to that of the existing "Ordre des Avocats"—namely, to deal with all professional delinquencies. The principal articles of the suggested council are as follows:—

Art. 3.—Local medical councils would be recognised under the law of May 12th, 1920. Each council would be administered by a committee composed of 6 if it represented 60 registered doctors, 9 for districts where 61 to 100 doctors were registered, 12 where over 100 doctors were registered, 15 where over 200 doctors were registered, and 24 in Paris. The president would have a casting vote. The committee should be elected for three years by ballot, on a clear majority of the votes of the members present, convened in general assembly, a third of its number retiring each year. The committee should elect its president annually.

Art. 4.—The electorate should consist of such doctors as have been in practice for three years in the district. This period should be extended to ten years for the first three years during which the law is in force. Doctors who have practised in the same district for ten years should be eligible for election.

Art. 5.—The committee of a local council should prosecute and punish, on its own initiative or following any complaints lodged, all infringements or errors committed by the doctors inscribed on the register or by their authorised substitutes. According to the extent of the infringement of the rules of medical ethics, the committee of the council could exercise the following disciplinary measures: (*a*) warning; (*b*) censure, with or without black-listing, with or without the suspension of the right to vote or to be elected, for a period not exceeding ten years; (*c*) fine, which may or may not be combined with the preceding penalty; (*d*) permanent or temporary suspension from the performance of any legal, medical, or educational function under State administration, in the departments, the communes, public institutions or in the public services, benevolent or mutual help societies, insurance societies, and so forth; this interdiction would be confined to one district and could only be inflicted for a second or subsequent offence; (*e*) deprivation of the privilege of practising medicine for one year or more; (*f*) erasure from the register. Suspension and erasure should be limited to one district. This penalty could only be applied in the case of a second or subsequent offence after judgment had been passed, in accordance with Art. 25 of the law of Nov. 30th, 1892. The practice of medicine during a period of suspension or after erasure from the register once judgment had been passed would be punishable as illegal practice.

Art. 8.—Petition of appeal against charges of incompetence, exceeding of duty, or violation of the law could be laid before the national medical council.

Art. 9.—There should be a national medical council, sitting in Paris, composed of 19 members. Among them should be the President of the Academy of Medicine, as President and member ex-officio, nine councillors from the Court of Appeal or from the State Council, and nine doctors elected by ballot every three years by the district councils. The national council should be recast every year up to a third of its membership, the districts being called upon in rotation to supply delegates.

The View of the Profession.

This proposal would give to the profession and to the public alike much greater satisfaction than the projected law deposited in the Chambre des Députés in February, 1923, a law which was incompatible with the traditions of liberty and independence of the French medical profession. On the other hand, many doctors are of the opinion that the medical syndicates at present existing could play a much more effective part if given adequate disciplinary powers. However that may be, the medical profession is at present agreed: 1. To strengthen its defence against the intrusion of undesirable elements whose presence would bring into discredit the vast majority of doctors who place their professional honour above every other consideration. Unworthy doctors must be struck off the lists, just as an unworthy priest is unfrocked or a dishonourable officer is cashiered from the army. 2. To create a tribunal of honour embodying the following two principles: (*a*) extension of the powers of the existing syndicates (compulsory enrolment in the syndicates), increased disciplinary powers and their effective application; (*b*) institution of a medical council on the lines of the present proposals or on some other basis. It is recognised that the doctors must take the lead in order that the law may not take the initiative against the profession.

Some decision is, anyhow, to be taken which will mark a new era in the French medical profession and will mean a radical change in existing conditions.

Radiotherapy in Cancer of the Œsophagus.

Dr. Jean Guisez, who has received part of the Prix Montyon from the Académie des Sciences, recently brought before a congress of surgeons a series of cases of œsophageal cancer which have been under his care for over a year. Some of the cases are of three to ten years' standing, yet he states that an apparently complete cure has been obtained. The patients before treatment all showed symptoms of dysphagia, but since the application of radiotherapy Dr. Guisez asserts that deglutition of all types of food has returned to normal, and that examination with the œsophagoscope showed complete disappearance of the tumour. In a few cases the results were obviously merely palliative, but in certain favourable instances the action of the radium was apparently complete and permanent. In all the patients diagnosis was based on endoscopy controlled by a microscopical examination of a section of the tumour. Two factors are necessary for successful application of treatment: (1) the tumour must be carefully defined to ensure the effective placing of the radium tubes, and (2) the lumen must admit a bougie No. 20 or 22, which contains the radium. Dr. Guisez advocates the use of the long bougie. Results have much improved since treatment was continued for longer periods (24 hours with a total of 90 hours) but given in smaller doses divided among several tubes. The platinum tube cases must be very thick, 1 to 1½ mm. Improvement in the patient's condition took place immediately; swallowing, which was previously impossible, became easy, and in many cases these results have persisted for years.

Death of Dr. Paul Oudin and Dr. P. A. Chaslin.

Dr. Paul Oudin (1851–1923) was born at Épinal and was educated in the Medical School of Strasbourg and subsequently in Paris, where he acted as interne des hôpitaux. As a pupil of Claude Bernard, he devoted himself when a young man to the study of the action of electrical currents on the organism. His work turned successively on diagnosis by electrical methods, radiotherapy, and the study of radiodermatoses. He was the first investigator in France to apply radiotherapy to the treatment of uterine hæmorrhage.—Dr. Chaslin (1857–1923), physician to the Salpêtrière, specialised from his student days in mental pathology. His work embraced chiefly semeiology and pathological psychology. He was the author of numerous publications on psychiatry, including treatises on the part played by dreams in the evolution of delirium, the relations of delirium to hallucinations, dementia præcox, and the responsibility of criminals and of the insane. His most important work is incorporated in two text-books, Mental Confusion (1895), and the Elements of Semeiology in Mental Cliniques (1912). By the death of Dr. Chaslin the psychiatric world of France has sustained a great loss, for he was a man who combined deep intuitive knowledge with a keenly developed critical faculty.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Changes in the Workmen's Insurance Act.

A RECENT government ordinance under the Emergency Power Act alters some of the provisions of the workmen's insurance law. The following are the principal provisions affecting the medical profession. A committee is to be formed for the whole Reich, consisting of five medical men, five representatives of the sick clubs, and three non-partisan members, which will be authorised to lay down general rules for the admission of medical men to club practice, for contracts between medical men and clubs, &c. The law provides for local arbitration courts, and a supreme arbitration court for disputes between the clubs and medical men. It has hitherto been a source of dissatisfaction that club patients often asked the club doctor to prescribe medicines where such were not strictly necessary, and that the medical man, to preserve or to extend his club practice, was only too often inclined to comply with the wishes of the patient, to the detriment of the club finances. Any medical man found guilty of doing so may be warned by the club, and when the warning has proved useless he may be struck from the list, even when the contract is still running. The free choice system becomes curtailed by a provision that if the number of panel doctors is greater than one for each 1000 insured, the club board is empowered to decline the admittance of more medical men to the panel. This provision is very hard for those young medical men who are waiting for admittance and are now, perhaps for a lengthy period, excluded from club practice which under present conditions means complete exclusion from medical practice. The actually diminishing numbers of medical students will be still further curtailed by this provision. When no agreement can be arranged between a club and the medical profession, the club is authorised to pay benefit money to its members at a higher rate, the members providing their own medical attendant. According to the old law, when a club had made a contract with a dispensing chemist for the supply of medicine, all the dispensing chemists of the locality had the right of making such a contract and of supplying medicine under its conditions. This provision has been repealed, so that one or more chemists may give credit to a club on the condition that the other dispensing chemists are excluded. A club may henceforth pay an additional sum to its members to buy medicine, when no agreement has taken place between the club and the local pharmacies. But in every case the individual club member is obliged to pay to the chemist 10 per cent. of the costs before the medicine is delivered to him, 90 per cent. being paid by the club. In some clubs —e.g., in the club of the Krupp works, where this procedure has already been voluntarily accepted—the result was that the club has saved about 50 per cent. of the expenses for medicine, the patients, of course, consuming much less medicine and drugs if they have to pay in cash a considerable sum. The provisions of the ordinance have caused great indignation amongst the medical profession, and a general strike is already suggested in medical circles.

Jubilee of the Deutsche Aerztevereins-Bund.

The Aerztevereins-Bund—the union of German Medical Associations—celebrated its fiftieth anniversary this year in Bremen. The union was founded in 1873 in Wiesbaden, where all the local medical associations of practitioners united under the presidency of the late Dr. Graf, a medical member of the German Parliament, who was afterwards elected chairman yearly for 20 years. The aims of the union were of an economic rather than of a scientific nature, medical legislation, hygienic questions, medical teaching, and medical examinations being the principal topics of discussion. Later on, when the sick club question became more and more urgent, the organisation of the union proved too loosely knit to engage in a successful battle. Therefore as early as 1900 a new organisation was founded by the late Dr. Hartmann, of Leipzig, its popular name being the Leipziger Verband. After the death of Dr. Hartmann the new organisation, in honour of its founder, was officially called the Hartmann-Bund. This association, which has local branches in every town and district of Germany, has adopted the methods of the trade-unions by settling with the various clubs tariffs for attendance on club members, collecting a strike fund, and organising strikes if necessary. Originally both organisations were distinctly hostile to the other, but very soon an agreement was established, and now both associations often work together, the strong organisation of the Hartmann-Bund being of great help to the older institution. The unfavourable financial situation of Germany made it impossible to convoke a general jubilee meeting because the expenses for railway fares, hotel accommodation, and so on are much too high for the average medical man and even for the delegates of the local branches. Therefore only the central committee met in Bremen, and, after disposing of current business, celebrated the fiftieth anniversary of the union.

Letters Patent for Dr. Friedmann.

In 1913 Dr. Friedmann, of Berlin, demonstrated before the Medical Society a method to cure tuberculosis by injections of turtle vaccine. His alleged favourable results were much criticised A commission instituted by the Government, under the chairmanship of Prof. Lubarsch, came to no definitive result because the opinions of the members differed too much as to the efficacy of the treatment. Dr. Friedmann had applied for a grant of letters patent for his remedy, although according to the German law a remedy itself can never be patented, a patent being granted only when the method of producing the remedy is new. In this way Ehrlich's salvarsan and Behring's diphtheria antitoxin had been patented. The granting of a patent to Dr. Friedmann had been challenged by some chemical works because, according to some, his method was not new. The Supreme Court of Leipzig has now given a verdict that the patent has been rightly given, and that two chemical works which had illegally produced the vaccine were liable to pay an indemnity. The court stated that Dr. Friedmann's process was quite a new one and that, in the opinion of many authorities, it had proved useful in the treatment of tuberculosis.

Help to the Ruhr Children.

The occupation of the Ruhr has had a bad effect on the children. They could not go regularly to school, the school premises being used as barracks for the occupying forces, while private dwellings often became insanitary through overcrowding. As child mortality and illness increased, many children were sent away to unoccupied Germany. This took place first in a rather unsystematic way, but later a committee was formed, consisting of members of the trade-unions, of benevolent societies, and of the authorities, which took the general organisation in hand. Local committees selected the children for evacuation. A distinction was, of course, made between healthy and weakly children. The healthy children were sent to country districts, where they were likely to receive an abundant supply of food, and where they might engage in some light occupation and attend the local school. The families to which they were sent were chosen by trustworthy persons, clergymen, and others. Not only in Germany, but also in some other foreign countries, Denmark, Norway, Sweden, and Switzerland, the children from the Ruhr were heartily received. Children in the second category were the weakly and the sick; they were selected by the school medical officers, and, with the help of the German Association for the Care of Children, were sent to sanatoriums, health resorts, and spas. Some 40,000 children were in this way taken out of the occupied district for several months, and then a new group was sent in their stead. The medical profession outside the occupied district took a particular interest in helping their professional brethren. The medical press published lists of medical men willing to receive in their homes children of their colleagues in the Ruhr district, in part absolutely free of charge, and in part at exceptionally low rates to cover at least a portion of the expenses which they could not bear alone under the present distressing condition of the profession.

Venereal Clinics.

According to a statistical record published by the German Health Office, there are at present 193 Advisory offices (Beratungsstellen) for venereal diseases in Germany, at which 106,753 patients received advice in the past year. This number has slightly diminished as compared to that of the preceding year, when the offices were frequented by 118,982 patients, of whom 77,307 were found to be infected. Of this number 44,000 were men and 33,000 women. 26 per cent. of the men and 15 per cent. of the women were married. Insurance under the Workmen's Insurance Act covered 62,000 cases.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Dangers of Domestic Electricity.

IN a paper read by Prof. Stephen Jellinek before the Teachers' Society the dangers involved by the extensive use of electricity in every-day life were described with a view to instructing the public on the best means of avoiding these risks. In accordance with an order by the Board of Education, instruction in domestic electricity is now compulsory in elementary schools. Prof. Jellinek pointed out that it was not the high-voltage current only which could be detrimental to the individual as was generally supposed. The ordinary household current of 110–220 volts used throughout the world for heating, lighting, and medical purposes might, under unfavourable conditions, produce a shock capable of causing serious or even fatal effects. If the person is in good conducting circuit with the earth such an occurrence is very likely to happen. Carpets or straw mats are considered a good protection, but if these happen to be wet, then the current can pass through the body. In sculleries, bathrooms, pantries, or cellars, where there are gas pipes, water pipes, or metal stoves, a person handling an electric apparatus or an electric light, always runs a certain risk. Even the touching of a cable of a lift is known to have caused a fatal injury. As the current is generally "earthed" via the legs and feet, the footwear must be carefully attended to by persons exposed to these risks. Wet shoes, or nails on the soles of an ordinary boot, or bare feet, are very dangerous in that respect. But, of course, individual tolerance plays an important part, as does also the psychical condition. An unexpected shock is much more dangerous than one which the person is expecting. Although the effects pass off very rapidly in many cases, it is important to disengage the connexion as quickly as possible, either by switching off the current or by pulling the patient away. In the latter case, the rescuer must be careful to stand on dry objects and to wrap his hand in a dry piece of cloth. If the affected person has stopped breathing artificial respiration must be instituted at once; life has been saved thus in many instances of electrocution. The burns resulting from the passage of electricity through the body are generally more or less painless and heal slowly, whilst nervous disturbances may remain.

Voluntary Workers of Welfare Centres.

A few days ago the second meeting of the above-mentioned social workers took place in Vienna, where some very interesting and useful papers were read. Thus Prof. Zappert emphasised the necessity of reinstating measles, whooping-cough, and epidemic parotitis as notifiable diseases, as thereby an enormous amount of injury to public health would be prevented. Provision for the care of infants and children suffering from epileptic seizures, from feeble-mindedness, and paralysis is quite insignificant in this country, and even more so for individuals suffering from enuresis. A widespread organisation should be instituted for these unhappy children. He also laid stress on the necessity of controlling the excessive indulgence in sports, nowadays so favourite a pastime of our youth. It may be added here that there exists a special "heart dispensary" in Vienna, under Prof. R. Kaufmann, where all members of sporting clubs can be regularly examined. Full records of many of these persons are already stored there. Dr. Moll pointed out that in spite of the sensibly diminishing general mortality-rate of infants in Vienna, the proportion of illegitimate babies is rapidly increasing. He urges the organisation of welfare-centres in the densely populated districts, and the establishment of such centres all over the country, as well as in the cities. Prof. Hamburger discussed the problem of combating tuberculosis in children. He said that infection took place only from man to man; the other possibilities hardly required consideration. In 75 per cent. of cases infection occurs through the family, by parents, other children, or nurses; in the other 25 per cent., through visitors or other household members. The age of the infected child is of utmost importance, the first year of life being the danger period. Hereditary predisposition and insanitary surroundings have much to do with the development of infection. Prof. Hamburger suggests the institution of "preventories," where children of diseased parents could be brought up or protected against infection. Dr. Smola urged the imposition of severe regulations to prohibit the sale of intoxicating liquors to juveniles, and Mr. Braunlich, the head of the Municipal Welfare Centre for Children, explained the measures adopted by the city of Vienna to ensure a stay of four to eight weeks in the country for all children pronounced below par by the municipal school doctors.

Alarming Increase of Criminal Abortion.

In a paper read before the Vienna Medical Society, dealing with the increasing frequency of intentional abortion within the last few years, Prof. Latzko stated that the records of one maternity hospital give a good insight into the actual conditions. Whilst in 1898 the ratio of abortions to births stood at 18·9 per cent., in 1908 it rose to 32 per cent., in 1913 to 57 per cent., and in 1921 it dropped to 44·8 per cent. of all births taking place in that hospital. If, however, we consider separately the married women and the single women, we find that amongst the older married women (over 25 years of age) the average number of abortions is fairly constant (10 per cent.). But amongst the younger women—under 25—the married women showed 30 per cent., the single women 90 per cent. of abortion in the year 1898. Ten years later the figure for the unmarried was 102 per cent., 1913 it was 201 per cent., and in 1921 it was 331 per cent.—i.e., more than three times as many abortions as births. In other words, the overwhelming majority of all abortions in single women must be regarded as intentional or, synonymously, criminal, whilst amongst the married women the ratio of 30 per cent.

has remained fairly constant for years. The social and economic conditions of the population (and not alone in Austria) seem to call for birth control, for it is much better to prevent pregnancy by contraceptive means than to leave the woman to take the risk of what is generally a non-medical attempt at abortion. In this country there is a strong party endeavouring to induce legislation to make artificial abortion before the third month a non-criminal procedure, and to spread the knowledge of contraceptive measures amongst the lower (poorer) classes of the population.

Convention as to Lunatic Persons.

Austria and Sweden have agreed to assist each other in helping to house or treat persons afflicted with mental disease, from one or other nation, by providing that such patients will be received in mental hospitals on the same footing as any native patient. In case such a person has to be sent back to his native country, all medical papers and histories, together with the necessary notes, will be handed over to the proper authorities. All costs and expenses incurred by one country for the subjects of the other are to be refunded in full.

Public Health Services.

SCHOOL MEDICAL SERVICES.

Gloucestershire.

The number of children on the elementary school registers in this county is 41,242; of these 11,744 were examined under the code groups, 10,752 showing defects requiring either treatment or further observation. Among the entrants 4·5 per cent. were found with seriously defective vision, nearly 3 per cent. with external eye disease, 1·5 per cent. with ear discharge, and 20 per cent. with defective conditions of the nose and throat. An effort is being made to deal with the children of pre-school age—a problem which must necessarily find a different solution in urban and rural districts. The nursing staff consists of eight whole-time county health superintendents, whose work includes health and tuberculosis visiting, and 111 district nurses. An important improvement has taken place in the cleanliness of the children, only 40 children being found with pediculi capitis for every 100 found 12 years ago. In addition there is a marked diminution in the degree of infection. Dr. J. Middleton Martin remarks that these results have been obtained only at the expense of a vast amount of work, 53,177 examinations of 43,580 children being made during 1583 visits to 516 departments. It is curious to find that the worst districts in respect of pediculosis are the purely agricultural areas in the north-east of the county; the mining area of the Forest of Dean is an area of low incidence. The new scheme at present provides treatment for school-children, those attending maternity and child welfare, and tuberculous patients. For carrying out treatment three general hospitals, five cottage hospitals, two tuberculosis dispensaries, and one specially constructed wooden building are utilised. The work is done by local practitioners and district nurses, the specialist services of the visiting staffs of the hospitals and of the county tuberculosis officer being available. Of the 11,377 children treated during the year, 7628 came under the local authorities' scheme. The arrangements whereby dental treatment is given on the same day as inspection is working smoothly, and the number of children treated has been doubled under these conditions.

Bootle.

The average attendance here is high, 11,592 out of a school roll of 12,801. Of these, 4023 were inspected in the code groups, and 2386 children were specially examined. At the routine examinations 21·3 per cent. were found without any physical defect, compared with 22·5 per cent. in 1921. Malnutrition accounted for 10·6 per cent. against 7 per cent. the previous year, defective vision for 17·2 per cent., enlarged tonsils for 16·3 per cent., adenoids for 1·5 per cent., and lung disease for 4·8 per cent. Of the entrants examined 54·2 per cent. were referred for treatment. A routine test of hearing by means of the forced whisper at a distance of 20 feet was carried out in all cases except where the noisy condition of the school premises made it impossible. In 2·6 per cent. of the boys and 2 per cent. of the girls the hearing was noted as defective. It would seem doubtful if the results obtained from the application of this rough test to all children are worth the time and energy expended on it. Forty children visited the aural and 177 the throat clinic. Altogether 1556 children made 12,783 attendances at the minor ailment clinic, and 160 children made 2312 attendances at the remedial exercises clinic, where a consulting orthopædic surgeon visits three times a year attended by an orthopædic instrument maker. Last year he examined altogether 72 children, recommending 25 for admission to hospital with a view to operative treatment, 13 for no further treatment, and the remainder for admission to or continuance at the clinic. The 160 patients attending this clinic included 58 mouth-breathers, 25 cases of round shoulders, 29 of infantile paralysis, 3 of rickets, 10 of scoliosis, and 10 recent fractures. Dr. F. T. H. Wood reports that in addition to the three special classes for dull and backward children a fourth has been established for older children, providing altogether for 90 cases. Eleven children from these classes were drafted back to the ordinary school, and 16 were pronounced to be mentally defective.

MENTAL HOSPITALS SERVICE.

By an Act of 1922 the administration of the *Three Asylums in Staffordshire* has been vested in a single authority, which has issued the annual reports of these three institutions in a single volume containing many points of interest. New visiting committees have been appointed, and the fact that two of these are composed exclusively of male members is commented on without approval by the visiting commissioners. The fact that one of these commissioners is herself a woman explains certain recommendations in their report as to the women's clothing, which argue investigations beyond the scope of masculine knowledge and interest. Apart from these criticisms, and certain references to roller-towels and scanty tooth-brushes, the commissioners have no fault to find. As regards diet, that at *Burntwood* is particularly commended; dinner in the main dining hall was "preceded by singing grace to an organ accompaniment, and music was continued during the meal." On the other hand, one searches in vain for any reference to the famous orchestra at *Cheddleton;* it is very much to be hoped that this remarkable feature of social life is being maintained in all the vigour which it displayed at the annual meeting of the Medico-Psychological Association held there in 1920.

It is left to the committees of visitors to criticise the state of the fabrics, which is evidently bad in many respects. Repairs have been neglected until not merely repainting but actual replacement has become necessary. In the case of Cheddleton some of the items in this count are startling. "The Nurses' Home, although opened in 1914, has never been painted, nor have the public rooms been furnished." "The need for new farm buildings does not grow less. The present accommodation is insufficient, necessitating an expenditure of £880 per annum on condensed milk, the shippons are dark and insanitary, tuberculosis is rife, and the subsoil is permeated with the filth of generations. The buildings remain a standing disgrace to the local authority." It is quite evident that the Staffordshire County Council must reconcile itself to immediate heavy expenditure in order to restore its property to a condition conforming to pre-war standards. This is a necessity which is being faced in some degree in institutions throughout the country, and no financial advantage appears likely to be gained by any further delay.

Each of these institutions possesses a dentist and a pathological laboratory. Burntwood is also grateful for the relief afforded by the services of a dispenser. A very notable piece of bacteriological work has been carried out at *Stafford*—namely, a determination of the effect of different methods of floor treatment on the bacterial content of the air in a ward. "For every 100 organisms deposited in ten minutes on a certain small area when a ward floor was undisturbed for three hours, 1211 were deposited 15 minutes after sweeping, 1439 after sweeping with damp sawdust and tea-leaves, 228 after polishing, and only 86 after the use of a vacuum dust extractor." The advantage of the latter method is obvious, particularly when the high rate of infection with tuberculosis in asylums is remembered. The rate of mortality from this cause at Stafford has fallen, but, as Dr. B. H. Shaw observes, it is still twenty times that of the general population. He deplores the absence of facilities for isolating tuberculous cases, and, further, the absence of separate accommodation for recent admissions. In patients suffering from severe insomnia the absence of noise is of the first importance, and "under existing conditions the exclusion of noise is impossible."

Considerable trouble has been experienced with the female nursing staff here, as elsewhere. The following observations on this subject, however, read somewhat strangely. "The Ministry of Labour, without actually refusing permits for Danish nurses to enter the country, has raised certain difficulties, in spite of representations being made that the educated class so required cannot under any circumstances enter into competition with English female manual labour." "Good wages, ample liberty, and considerate treatment have so far failed to induce them to forego the temptation of matrimony under circumstances which do not to the onlooker present any compensating advantages." Each of these statements appears to call for some further explanation. An admirable feature at Burntwood is a "Club Ward," confined however, to the male side, where selected patients are allowed special privileges.

In the annual report of the *Derby Mental Hospital* no changes of note are recorded. The superintendent is assisted by only one (temporary) colleague; it is true that much larger institutions than this (409 patients are resident at Derby) are run by a staff of three medical officers, but between three and two there is a difference much greater in asylum practice than in mathematics, and in the more prosperous times, which perhaps lie ahead, these two gentlemen will, no doubt, be grateful for the assistance of a third colleague.

MEDICAL CANDIDATES FOR PARLIAMENT:

SUCCESSFUL AND UNSUCCESSFUL.

THE complete list of medical men entitled to sit in the new House of Commons is as follows:—

Members.	*Constituency.*	*Party.*
Sir George Berry ..	.. Scottish Universities ..	C.
Dr. W. A. Chapple ..	.. Dumfries	L.
Dr. F. E. Fremantle	.. Hertford, St. Albans ..	C.
Dr. L. Haden Guest	.. Southwark, North.. ..	Lab.
Mr. Somerville Hastings	.. Reading	Lab.
Sir Sydney Russell-Wells	.. London University ..	C.
Prof. T. Sinclair ..	.. Queen's University, Belfast	C.
Dr. E. G. Spero ..	.. Stoke Newington.. ..	L.
Dr. J. H. Williams ..	.. Carmarthen, Llanelly ..	Lab.
Lieut.-Col. T. S. Beauchamp Williams.	Lambeth, Kennington ..	Lab.

C., Conservative; L., Liberal; Lab., Labour.

A list of medical candidates is here given, showing the individual position at the poll, and the number of votes registered. An asterisk indicates membership of the last House of Commons, while a dagger sign indicates that the candidate contested this or some other seat at the last general election.

List of Medical Candidates for Parliament.

Constituency.	Name.	Position at poll.	Votes registered.
Universities:			
London.	Sir S. Russell-Wells.*	1	(1) C., 4,037 (2) L., 2,593 (3) Lab., 1,420
Scottish.	Sir George Berry.*	U	—

Lanark, Lanark.	Capt. W. E. Elliot.*	2	(1) Lab., 11,384 (2) C., 11,154

U, unopposed.

There are thus ten medical Members to take the place of the twelve medical Members in the last session of Parliament. While this representation of medicine is strong and shared by the three political parties, the absence especially of Captain Elliot and Dr. Salter will be a real loss to the House of Commons, and one which we hope will soon be made good.

A SPECIAL course in Infants' Diseases for medical officers of welfare centres and others will be given at the Infants' Hospital, Vincent-square, Westminster, London, S.W., from Jan. 7th to 19th, 1924, under the auspices of the Fellowship of Medicine. Those taking part in the course will include Drs. W. E. Robinson, Norah Schuster, Eric Pritchard, Bertram Shires, Donald Paterson, Helen Mackay, Amy Hodgson, Vincent Denne, H. MacCormac, and Mr. Tyrrell Gray. Further particulars may be obtained from the Secretary to the Fellowship at 1, Wimpole-street, London, W. 1.

Correspondence.

"Audi alteram partem."

THE SHORTAGE OF NURSES.

To the Editor of THE LANCET.

SIR,—I am writing neither as an official of the College of Nursing, nor as a member of the General Nursing Council for England and Wales, but I was so interested in your article on Nursing Education in America in your issue of Dec. 1st that I should be grateful if you would permit me to offer one or two comments as one specially interested in the system prevailing in this country. I have lived in America and amongst American nurses and seen a fair amount of their hospital training schools, and although I am very willing to concede that we may learn something from America, we are, I think, at this present stage, viewing nursing from a somewhat different standpoint.

With reference to the establishment of a subsidiary service in America, I think I am correct in saying that many leaders of nursing there are viewing the results with anxiety: (1) The separation of the hospital administration from the training school administration would be an obvious improvement. At present the training school administrator is often overburdened, and the educational and personal needs of the nurses in many cases suffer accordingly. (2) I contend that a great deal of routine domestic work might be eliminated, but nursing is not only a dramatic performance of highly skilled treatments, it is the repetition of simple domestic duties performed perfectly and with understanding. This perfection cannot be attained without almost unlimited repetition, and any woman having only "a very brief training in bedside routine" cannot learn in that time to realise its significance. The medical profession may argue that the V.A.D.'s did magnificent work with their short and limited experience. There was the unique impetus of war service behind all their work, and a great number were picked women—the smallest fraction of them continued to nurse after the war, and it is nothing but the discipline of a continued training can make it possible for women to deal with the dullness of mild general sickness. (3) If the medical profession would calculate how much acute illness had been obviated by the skilful care of mild sickness by a well-trained nurse, they would look upon her as a factor in "prevention" as well as "cure." (4) To establish a subsidiary service is to risk in the future the poorer members of the community being nursed by the "aide" or "attendant," and the richer members engaging the skilled nurse.

I think the type of woman a subsidiary service with its limitations is likely to attract will not be the type of woman to answer the requirements of the medical profession, no matter how limited they may be. Unless one is actuated by some "professional" motive, by which I mean a motive of service of a high standard, nursing is often not even pleasurable. I might go as far as saying it is arduous and disagreeable. It is neither when based on knowledge and service. The State is now only requiring that nurses shall be safe to nurse the sick. The standard set by the State can never go far beyond that, because the sick *have* to be nursed, extra qualifications must be obtained after general training.

I should like to recommend that: (*a*) Before establishing a subsidiary service, let us obtain from *reliable sources* the result of the experiment in America. (*b*) Call a conference between leaders of the medical and nursing professions to ascertain the real need. (*c*) Appeal to the Ministry of Health to make a survey of the nursing services of the country, the result of which would be invaluable in arriving at the real nursing needs of the community. (*d*) Reorganise our present system in hospitals with a view to making the training more attractive. At present it is often unattractive to educated women, the initiative and mind of the woman not being allowed sufficient latitude. (*e*) Establish adequate pay and a superannuation scheme for all nurses, which will ensure educated women some provision for their later years.

I am, Sir, yours faithfully,
GERTRUDE COWLIN.

Grove End-road, N.W., Dec. 8th, 1923.

⁂ We are in substantial agreement with the proposals made by Miss Cowlin in the last paragraph of her letter, but since an organised subsidiary service on the lines suggested in the Rockefeller report has not yet been established in America a period must necessarily elapse before its results are available for consideration.—ED. L.

THE IMPORTANCE OF NASAL SINUS INFECTIONS.

To the Editor of THE LANCET.

SIR,—The case of exclusively sphenoidal sinusitis recorded by Dr. W. C. Rivers (cited in his letter in your issue of Nov. 17th) is of great interest and value as showing that a focal pyogenic infection of one of the smaller sinuses may cause just as marked pulmonary and general symptoms simulating pulmonary tuberculosis as may a maxillary or mixed sinus infection. Furthermore, as Dr. Rivers has shown, there are similar cases from sinusitis limited to the frontal or ethmoidal cells.

Dr. A. L. Yates's article and his subsequent letter in your issue of Dec. 1st suggest that it is the pus from the nose running back into the pharynx, &c., which is recovered and coughed up, and which accounts for the wasting and sometimes the febrile reaction. Yet surely it is not the spreading of pus but the spread of infection from the nasal discharge to the larynx, trachea, and bronchi that causes the bronchorrhœa and sputum. Dr. Yates has done good service in directing attention to purulent nasal sinusitis as a cause of simulated phthisis. But as he points out "by anterior rhinoscopy the nose generally appears normal and the airway as a rule is good on both sides," and thus he too finds the sinus cases with relatively scanty intranasal discharge that can only be seen by posterior rhinoscopy are those which cause spreading infection and toxæmia rather than the more typical sinusitis with nasal obstruction and profuse purulent discharge anteriorly and posteriorly.

Provided a sinus infection by pyogenic organisms has been definitely established and persistent, the more profuse the polymorphonuclear lymphocytes and the more active the phagocytosis the less the liability to spreading infection, and conversely with relative paucity of pus cells the greater the liability to the infection spreading. Hence, given such a focal infection, it is the virulence of the infecting organisms rather than the amount of pus present that is the important factor when we come to consider spread of infection. Pus is always present, sometimes obviously, often so scantily that to the naked eye the discharge seems merely mucus by the time it is recovered.

Thus I recommend the routine bacteriological examination of these discharges to confirm or refute the diagnosis. Until the lessons such examinations enforced my attitude was precisely that now adopted by Dr. Yates. If one finds to one's surprise on exploring a sphenoidal sinus in a case of canalicular optic neuritis no obvious pus but a pure culture of pyogenic cocci, and after the washing out and disinfection the visual colour fields, and vision obviously improve and sometimes become normal; if articular fibrositis similarly shows striking improvement under similar circumstances, and these happy experiences are repeated again and again, one realises that it is not only cases where pus is obvious to the naked eye that will benefit by appropriate treatment that Dr. Yates has so well emphasised. But only after years went did I learn to realise that it is the infection, not the pus, that counts and that sometimes the less the pus the more mischievous the infection. I am not referring to slight infections of the sinuses only detectable by microscopical methods and not causing serious symptoms, for many such accidental revelations of organisms being present are really immaterial and they do not warrant operative measures, if only that simple working out often suffices to remove all trace of these slight, transient, and trivial infections.

Yet we have learnt that quiescent, apical, dental sepsis only detectable by radiography may be of greater clinical import than an obviously carious tooth or even an acute periodontal abscess that declares its presence by acute local manifestations.

I am, Sir, yours faithfully,
Patrick Watson-Williams.

Clifton, Bristol, Dec. 10th, 1923.

To the Editor of The Lancet.

Sir,—In his letter commenting upon my article on Unsuspected Nasal Sinus Disease Dr. P. Watson-Williams raises points important for the rhinologist who has to investigate the extent of the sinusitis. The object of my article was to direct the attention of those engaged in general medicine and surgery to various conditions which infections of the nasal sinuses can produce and to emphasise the fact that it is by routine examination alone that we can avoid frequently missing the primary cause. For this purpose I thought it best to quote cases in which the visible pus obtained left no doubt as to the diagnosis. In the diagnosis of sphenoidal sinusitis I have found Dr. Watson-Williams's syringe of great value. But where no macroscopic pus is obtained in the fluid sucked back from the sinus I think great caution should be used in making a diagnosis from the microscopical evidence obtained. No matter what precautions one takes in applying antiseptics to the septic vestibule of the nose it is impossible to avoid contamination of the cannula passed down into the sphenoidal sinus. A rhinitis is often present in these cases, and as the investigation is done in the recumbent position infective material may pass back from the pharynx. A leucocytosis found in the fluid would be good evidence, but a positive diagnosis cannot safely be made from the finding of bacteria unless the film shows large numbers. My personal experience is that maxillary sinusitis is far more common than sphenoidal. I am, Sir, yours faithfully,

London, W., Dec. 10th, 1923. T. B. Jobson.

THE TREATMENT OF LIVER ABSCESS BY ASPIRATION.

To the Editor of The Lancet.

Sir,—In The Lancet of May 12th, 1923, there appeared an article on this subject written by Drs. P. Manson-Bahr, G. C. Low, J. J. Pratt, and A. L. Gregg. I am a Government medical officer working far from any proper hospital and with little in the way of medical equipment. Soon after reading this article I had the opportunity of treating a case of liver abscess on these lines with excellent results. In my experience liver abscess can now be treated in the out-patient department or in a dispensary with even more simple instruments than those of the London School of Tropical Medicine; in some cases not even a local anæsthetic is necessary.

On Sept. 29th, 1923, an adult male came to the dispensary here complaining of abdominal pain and swelling of legs. On examination he was thin, with normal pulse and temperature; the right side of the abdomen was occupied by a tumour, large, round, and tense—looking as though there were a child's inflated football in the abdomen—and reaching well below the umbilicus level. There was also pressure œdema of both legs. On palpation the tumour was tender, and deep fluctuation was felt.

Without employing any local anæsthetic, I passed into the tumour, at its most prominent point in the nipple line just above the umbilicus, the needle ($2\frac{1}{2}$ inches long) of an ordinary exploring syringe (capacity 2 dr.). The needle had to be pushed in right up to the hilt before the abscess cavity was reached, and then typical thick anchovy-paste liver-abscess pus came out under moderate pressure. As it took such a long time to evacuate the pus with this small syringe (I have no Potain's aspirator), by means of a small piece of rubber tubing I connected the needle with a small metal ear syringe of $1\frac{1}{2}$ oz. capacity, and by this means in about half an hour removed 35 ounces of pus. I then injected 1 g. of emetine hydrochloride intramuscularly, and repeated the injection daily for 15 days. I kept the patient under observation, but gave no other treatment.

The patient made a rapid and uneventful recovery. By the end of the first week the liver was three fingers-breadth below the costal margin, and the œdema of the legs had gone. Treatment was stopped on Oct. 13th, the fifteenth day; the liver was then normal and no longer tender, and the patient was putting on flesh. Six weeks later he was quite well.

My experience of the resistance of natives to liver abscess is the reverse of that mentioned in the paper referred to above. I do not see many cases here, and have met with none in Europeans. The case I have narrated must have had his abscess for several months, and was not acutely ill when I saw him. Ten years ago I had a similar case of seven months' history in an educated native. I operated by the transthoracic route, resecting a rib, and the man is now alive and well.—I am, Sir, yours faithfully,

M. C. F. Easmon, M.B., B.S. Lond.,
Medical Officer, Sierra Leone, W. Africa.

Nov. 26th, 1923.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Lt. F. G. Hunt to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Lt.-Cols. E. B. Knox and J. Matthews retire on ret. pay.

Capt. A. Rodd, from the half-pay list, is restd. to the estabt.

Capt. W. L. Partridge retires, receiving a gratuity.

TERRITORIAL ARMY.

Capts. R. C. Clarke and O. Teichman to be Majs.
Lt. M. D. Mackenzie is restd. to the estabt.
W. B. McCall and E. L. Hancock to be Lts.

ROYAL AIR FORCE.

Squadron Leader P. T. Rutherford is granted a permanent commission in the rank stated.

J. M. Rourke is granted a short service commission as a Flying Officer.

Cremation in Manchester.—The annual report of the Manchester Crematorium for the year ending in August, 1923, shows that 222 cremations took place as compared with 206 in the previous year and 211 in 1921. Since the opening of the crematorium in 1892 the number of cremations amounts to 3826. In Great Britain for the year just ended the total number of cremations was 1923 against 2058 in 1921–22. In Manchester the cremation fees during the year totalled £1338.

Supply of Insulin in Ireland.—In a letter to the lay press Sir John Lumsden, Vice-Chairman of the Joint Committee of the British Red Cross Society and Order of St. John, announces the steps that are being taken to provide a supply of insulin for poor patients in Ireland. Since the Free State Government finds itself unable to provide any funds at present for this purpose, the Joint Committee has made a grant of £500 and Sir John Lumsden appeals to the public to provide an equal sum. It is calculated that £1000 would provide enough insulin to supply urgent cases for a considerable time. An Irish correspondent informs us that the Connaught Laboratories at Toronto have already promised to supply insulin at very reduced prices for the use of poor patients in hospitals, and the Joint Committee hopes to be able to obtain equally generous terms. In order that the insulin may not be wasted in indiscriminate use and on unsuitable cases, the Joint Committee is establishing a small insulin committee of physicians and others interested to advise as to distribution. It is to be hoped that the sum for which Sir John Lumsden appeals may speedily be forthcoming.

Obituary.

SIR FREDERICK TREVES, BART., F.R.C.S. ENG., M.D., M.CH. (HON. CAUSA), T.C. DUB., LL.D. ABERD.

Sir Frederick Treves, whose death occurred in a nursing home at Lausanne on Dec. 7th in his seventy-first year after a brief illness from peritonitis, was a man of many-sided interests, who enjoyed a great reputation not only as a surgeon, but also as an entertaining writer of books on travel at home and abroad. He was born at Dorchester in 1853 of old Dorset yeoman stock, and after two impressionable years under the tutelage of the Rev. W. Barnes, "the Dorset poet," he entered the Merchant Taylors' School, then in Suffolk-lane in the City. His medical education began at the London Hospital, where he qualified as Licentiate of the Society of Apothecaries, and a year later, in 1875, he obtained his Membership of the Royal College of Surgeons of England, the Fellowship following in 1878.

Happy chance played a large part in selecting the path of Treves's future activities. Though intending to settle down as a general practitioner in Derbyshire, he was induced by a friend on the staff of the London Hospital to take up a hospital career. He obtained the post of surgical registrar at the London Hospital, and from that beginning he rapidly won his way to the highest staff appointments. He took an active share in the management of the medical school and was largely responsible for founding the Students' Union. In 1881 he was appointed Wilson Professor of Pathology at the Royal College of Surgeons, and five years later combined these duties with those of the Hunterian Professor of Anatomy at the same College—a striking testimony to his skill as an anatomist and as a teacher. His Hunterian lectures, based on hundreds of original dissections, shed new light on many hitherto obscure or erroneous anatomical conceptions. A "Manual of Surgical Applied Anatomy," first published in 1881, was translated into several languages and still holds a place in the regard of students. Treatises of a very practical nature followed on scrofula, hæmophilia, and hernia. Treves was one of the pioneers of abdominal surgery; at this time, before the revolution of Lister, an almost virgin field. His essay on Obstruction of the Intestine (1884) gained him the Jacksonian Prize of the Royal College of Surgeons, as well as high commendation from Sir Spencer Wells. Later on came the "Manual of Operative Surgery" and the popular students' handbook of "Surgical Operations." So great in fact was Treves's professional activity as a surgeon, a teacher, an examiner, and a steady contributor to medical literature that at the early age of 45 he found himself compelled to give up hospital practice in the interests of his private patients.

On the outbreak of the South African War Treves was appointed consulting surgeon to the Forces, and took part in the Relief of Ladysmith. Deeply impressed by the lack of efficient medical service in the field—though well-intentioned helpers were numerous enough—he became one of the founders of the British Red Cross Society, and was the first chairman of its executive committee. "The Tale of a Field Hospital" is the poignant story of his experiences in the campaign. Although he never strove for public honours, in 1900 he was appointed surgeon extraordinary to Queen Victoria, and in the following year serjeant surgeon to King Edward, from whom he received the decorations of C.B., K.C.V.O., and G.C.V.O. In June, 1902, shortly before his coronation, King Edward fell seriously ill, the condition being diagnosed as perityphlitis. Surgical interference was advised, and "to Sir Frederick Treves was committed the heavy responsibility of performing the operation."[1] The operation, as is well known, was completely successful, and as a result, Treves's reputation stood higher than ever. He was created a baronet, and his practice became little short of overwhelming. In 1908, although in full vigour, he retired from practice, feeling, doubtless, that he had reached his zenith as an operator. The key to his full and distinguished life might be put in his own words, when delivering his rectorial address at Aberdeen University in 1908: he impressed upon the students that "the real factors in success were health, serviceable knowledge, sympathy and honesty, industry being presupposed."

"H. T.," a life-long friend, writes of him: "Treves was of a nature very precise. His habit of mind was to reduce all subjects to headings, duly numbered, with the result that he often missed the delicate side of things. Nevertheless, this sense of extreme order made him one of the best teachers a medical student could have. He was therefore followed in the wards by a vast crowd, and every case made simple for the ordinary mind. With his operations he was the same—a clear exposition at first, followed by a complete success. His method of teaching was rendered more attractive by a constant flow of sarcasm directed against his dressers or even his house surgeon. At home he lived in the simplest way, everything arranged to allow him the most complete use of his time. He was up very early, doing his writing before breakfast. His happiest days were spent in and on the sea—he held himself the certificate of a master mariner—and there was between him and the sailors and fishermen some natural bond. In earlier times he might have been a great explorer; as it was, a very real gift for exact observation and discovery was turned to other uses, sometimes perhaps to his own regret."

Treves did not retire to idleness, but from 1908 up till the outbreak of the late war, he travelled and wrote widely. His books include accounts of the West Indies, Uganda, Palestine, and Italy. He spent several years at the Thatched House Lodge in Richmond Park, lent him by King Edward, whose close and confidential friend he remained, a friendship which was continued by King George. During the European war Treves again took up the burden of professional life and was appointed President of the Headquarters Board at the War Office. He was also a member of the War Office Sanitary Committee, and he devoted himself to the Red Cross to the point of seriously straining his physical powers. Since 1920 he had lived in France, writing several delightful books, including "The Riviera of the Corniche Road" and "The Lake of Geneva." His last, "The Elephant Man and Other Reminiscences" was reviewed in these columns but recently, and gives an insight into Treves's sympathy and understanding. Anyone who had worked for years, as he did, in a great hospital must have accumulated a store of facts dealing with various aspects of human nature in which the pathetic and the comic were intimately blended; but few, indeed, could put their recollections into print with the blend of humour and charity which characterised this book.

Sir Frederick Treves married in 1877 the youngest daughter of Mr. A. S. Mason, of Dorchester, by whom he had two daughters. The elder is the wife of General Sir Charles Delmé-Radcliffe; the younger died of acute appendicitis. His body was cremated at Lausanne preparatory to burial in this country.

ARTHUR WILLIAM HARE, M.B., C.M., F.R.C.S. EDIN.

ON Nov. 25th, at Gateshead-on-Tyne, the death took place from syncope following pneumonia of Arthur William Hare, sometime professor of surgery at Owens College, Manchester. Born at Darlington in 1861, he was the younger surviving son of the late Mr. Samuel Hare, private secretary to the late Mr. Arthur Pease, M.P. He was educated at Oliver's Mount School, Scarborough, and at Edinburgh University, where he graduated with honours in medicine and surgery in 1882. Subsequently he obtained the Fellowship of the Royal College of Surgeons of Edinburgh by examination. Prior to graduation Mr. Hare had been appointed resident surgeon in Edinburgh Royal Infirmary, and in preparation for the duties of the post he spent six months in the medical schools at Vienna under Prof. Bilroth and Dr. Wölfler. After visiting the surgical clinics of Halle, Leipzig, and Berlin, he returned to Edinburgh and became assistant in the Surgery Department at the University and house surgeon to the Royal Infirmary under the late Prof. Chiene. In 1883 Mr. Hare returned to Berlin at the desire of Mr. Chiene to establish a bacteriological laboratory for observation and research, and by the courtesy of the German Imperial Board of Health officials, he was enabled to study bacterial research in Koch's laboratory. He was elected senior president of the Royal Medical Society, Edinburgh, for the year 1883–84, and in 1885 he published, with the late Prof. G. Sims Woodhead, a work on the ætiology of infective diseases called "Pathological Mycology." In 1886 Mr. Hare was elected a Fellow of the Royal Society, Edinburgh, and in 1888 he was appointed professor of surgery at Owens College, Manchester. He acted as honorary surgeon to Ancoats Hospital, Manchester, and examiner in surgery at Victoria University, but owing to a breakdown in health he resigned these posts in 1893. After travelling for his health in America, Mr. Hare settled at Newquay, Cornwall, where he became widely known as a surgeon. In 1915 he took up a commission in the R.A.M.C., but was forced to resign on account of ill-health some nine months later, and soon afterwards underwent a severe operation at Newcastle-on-Tyne. On recovery he became school medical inspector for the borough of Gateshead, which position he held until his death. Mr. Hare's systematic works included "Cranial Surgery," "Bandaging," and "The Surgical Treatment of Intracranial Tumours," while he contributed articles to THE LANCET,[1] "Chambers's Encyclopædia," and other publications. As a speaker Mr. Hare possessed unusual power, and his integrity of character, his courtesy, culture, and unfailing sympathy endeared him to all with whom he came in contact. His loss will be deeply felt by a wide circle of friends.

---

[1] THE LANCET, 1902, ii., 29.

CHARLES ERNEST ASHTON, M.R.C.S. ENG.

Charles Ernest Ashton, who died at Reims on Nov. 24th, was a member of the ancient Lancashire family of that name; he was born on August 16th, 1855, the younger son of Commander Herbert Ashton, R.N., of Hefferston Grange, Cheshire. His father saw much active service afloat between the years 1808 and 1816, being present at the embarkation of Moore's army after the battle of Corunna, the siege of San Sebastian, and the passage of the Bidassoa by Wellington's army, as well as assisting at the cutting out of innumerable brigs in the Bay of Biscay. The son, Charles Ernest, was educated at the Oratory School, Edgbaston, under Cardinal Newman. Later he matriculated at the University of London and became a student at St. Bartholomew's Hospital, where he served as dresser to Mr. Callender, qualifying M.R.C.S in 1881. He spent a good many years in holding resident appointments in this country; he was assistant house surgeon to the Derby Infirmary, house surgeon to the Wolverhampton General Hospital, and resident medical officer for four years to the French Hospital, London; in 1888 he spent nine months in Dublin at the Rotunda Hospital. After this he retired from the practice of his profession and went to live in France, dividing his time between Paris and Nice; he will be much missed by his poorer neighbours, for although he did not engage in practice, he was ever ready to help with advice and gratuitous treatment. His cheerful disposition enabled him to face his last trying illness, of more than 18 months' duration, with unabated courage.

Medical News.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A variety of post-graduate courses have been arranged for January, 1924, and full particulars of each of those mentioned below can be obtained from the Secretary of the Fellowship at 1, Wimpole-street, W. A further course in children's diseases will be given at the Infants Hospital, Vincent-square, from Jan. 7th to 19th. Clinical lectures and demonstrations will be given each afternoon, and in addition visits will be paid to places of interest in connexion with infant welfare work. An intensive course in urology will be given at St. Peter's Hospital for Stone, Covent Garden, from Jan. 7th to Feb. 2nd, inclusive. The course will consist of clinical work and lecture-demonstrations by members of the staff each afternoon, covering all aspects of urinary disease. A course of lectures in the diagnosis and treatment of common diseases of the nervous system will be given at the West End Hospital for Nervous Diseases from Jan. 7th to Feb. 11th in the out-patient department. A series of eight demonstrations in the diagnosis and treatment of the acute infectious fevers will be given by Dr. Frederic Thomson at the North-Eastern Fever Hospital, Tottenham, on Wednesday and Saturday mornings at 11 A.M., from Jan. 9th to 26th.

Dr. Aubrey Montague, chief medical officer, Fiji, has been appointed a member of the executive council of the Colony.

HUNTERIAN SOCIETY.—The second dinner meeting of the Hunterian Society will be held at Simpson's Restaurant, Cheapside, on Dec. 17th, at 7.30 P.M. After dinner a discussion on the Influence of Ductless Glands in Infancy, Middle, and Old Age will be held; the following speakers will take part: (1) General, Dr. Langdon Brown; (2) Infancy and Childhood, Dr. J. H. Thursfield; (3) Middle and Old Age, Dr. Leonard Williams; (4) Psychological, Dr. Crichton Miller.

SOCIETY OF APOTHECARIES: LIVERY DINNER.—This dinner was held in the ancient hall of the Apothecaries' Society on Dec. 4th, the Master, Dr. Thomas Wakefield, presiding. Among the guests were the Medical Directors-General of Navy and Army, the Presidents of the Royal Colleges of Physicians and Surgeons, and the re-elected Member of Parliament for the University of London. The toast of "The Navy, Army, and Air Force" was proposed by the Master and responded to by Vice-Admiral J. Chambers and Sir William Leishman. "The Royal Colleges and the Universities" was proposed by Dr. A. D. Brenchley, Senior Warden, and in response Sir John Bland-Sutton devoted to the consideration of faith in drugs a witty speech in which historical knowledge, business acumen, and professional liveliness were duly blended. Sir Sydney Russell-Wells also replied. "The Society of Apothecaries of London" was proposed by Dr. T. J. Duffield, and responded to by Dr. F. Gordon Brown, Senior Past Master of the Society. Dr. T. Vincent Dickinson, Junior Warden, proposed "Our Guests." The occasion was attended with that genial solemnity and lavish hospitality that distinguishes the society's banqueting and renders public eating something more than a dull though satisfying repast. A programme of music was contributed by Miss F. Holderness, Miss W. Stocken, and Mr. George Ison.

DONATIONS AND BEQUESTS.—The late Miss Margaret Lucy Augusta Boileau, M.B., B.S., of Wymondham, Norfolk, left by will, among other bequests, £200 to the Norfolk and Norwich Staff of Nurses, Limited; £100 to the Norfolk and Norwich Hospital; £100 to the Royal Free Hospital, Gray's Inn-road, W.C.; and £100 to the Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Mr. James Smith, Kelvinside, Glasgow, left £1250 to the Royal Infirmary, Glasgow, to endow a bed in memory of his mother; £500 each to the Western Infirmary, the Victoria Infirmary and the Royal Samaritan Hospital for Women, Glasgow; £300 to the Royal Hospital for Sick Children Glasgow; £250 to the East Park Home for Infirm Children; £200 each to the Royal Maternity and Women's Hospital, and the Association for the Relief of Incurables; and £100 to the McAlpin Nursing Home, Glasgow.—By the will of the late Mr. Willsher Mannering, of Dover, the testator left £1000 to the Royal Victoria Hospital, Dover.—Sir John Bell, a former Lord Mayor of London, has given £1000 to the fund for building a new wing to the King Edward VII. Hospital as a war memorial.

---

[1] Cranial Surgery, THE LANCET, 1888, i., 207, 307, 407.

The house and library of the Royal Society of Medicine will be closed from Monday, Dec. 24th, to Thursday, Dec. 27th, both days inclusive.

Chelsea Clinical Society.—A meeting will take place at the Club Room, St. George's Hospital, on Dec. 18th, at 8.30 P.M., when a discussion on the Manipulative Treatment of Joint Diseases will be opened by Mr. Frank Romer.

A conversazione, at which the Prince of Wales will be present, will be held at the Middlesex Hospital on Dec. 18th, from 8.30 to 11 P.M. Scientific exhibits will be on view and demonstrations will be held, and research departments and new laboratories will be open for inspection.

Middlesex Hospital Medical School. — Sir James Kingston Fowler will deliver an Emeritus Lecture, illustrated by cinematograph, to-day, Friday, Dec. 14th, at 3 P.M., in the large lecture theatre of the Medical School. The subject of the lecture will be a Tuberculosis Settlement.

University of Manchester.—Prof. S. J. Hickson, M.A., F.R.S., who has occupied the Beyer Chair of Zoology since 1894, will retire at the close of the present session in September, 1924, under the age limit.

Glasgow Royal Infirmary: the Lister Ward.—At a meeting of the board of management of the infirmary it was decided by a majority to proceed with the demolition of all that portion which remains of the old infirmary buildings. This includes the Lister Ward, the preservation of which has been so strongly urged from many quarters, as reported in our columns recently.

Liverpool Psychological Society.—This society has now been inaugurated under the presidency of Prof. Alexander Mair, of the University of Liverpool, supported by Dr. Betts Taplin as Vice-President, and an influential committee. The society intends to pursue the systematic investigation of the recent developments of the science. Further information can be obtained from the Secretary of the Society, the University, Liverpool.

A Comfort for Invalids.—The combination chair for invalids devised by Sir Charles Brown, F.R.C.S., and briefly described in these columns (July 7th, p. 49) has now been presented by the inventor to the Preston Royal Infirmary, the Preston St. Joseph's Hospital, and to King's College Hospital, Denmark Hill, London, where it can be seen in use.

Small-pox in England and Wales.—The number of cases of small-pox notified in the sanitary areas of England and Wales shows a tendency to rise from week to week. During the week ended Dec. 1st, 45 cases were notified as follows: Derbyshire 12 (Heanor 4, Blackwell R.D. 8); Gloucestershire 13 (East Dean R.D.); Notts 16 (Hucknall 13, Kirkby-in-Ashfield 2, Stapleford R.D. 1); Yorks W.R. 4 (Adwick-le-Street 3, Bentley-with-Arksey 1). It will be noted that a majority of cases are occurring within certain small and restricted areas. Spain is the source of a recently imported case of small-pox in the person of a resident in Wood Green, Middlesex, who had recently been on a business visit to that country. He appears to have contracted the disease there on or about Nov. 22nd, and travelling overland to London reached this country on Dec. 7th. It is hoped that the prompt measures taken will have sufficed to check the spread of infection after his arrival at his home, but there is risk from the fact that, as his eruption came out on his way home and presumably rendered him infectious by the time he reached this country, he may have infected other people met on his journey between his port of arrival and final destination. His case is described as being not severe.

Bath Clinical Society.—A meeting was held at the Royal United Hospital on Dec. 7th, Dr. W. P. Kennedy, the President, being in the chair, when the following cases and specimens were shown:—Dr. R. G. Gordon: Osteitis Deformans and a case of Arthritis treated by Protein Shock. Dr. C. A. Marsh: Diabetes treated by Insulin. Dr. F. G. Thomson: Idiopathic Familial Muscular Atrophy. Mr. F. Fraser: (1) Repair of the Lower Eyelid by Pedicle Flap; (2) Pegging of Hip-joint for Intracapsular Fracture; (3) Elving's Operation of Sympathectomy for Progressive Gangrene of Both Lower Limbs. Mr. C. Terry showed a slide of a mixed-celled sarcoma removed from the sciatic nerve. Dr. Preston King read a paper entitled National Health. He dealt with the defects of the panel system and the necessity of a closer coöperation between the profession and the State in the province of preventive medicine.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Dec. 17th.

SPECIAL DISCUSSION: at 5 P.M.

On Chronic Abdominal Pain in Nervous Women, to be opened by Dr. Robert Hutchison, followed by Dr. Fairbairn, Dr. James Collier, Dr. Crichton Miller, Dr. E. I. Spriggs, Dr. M. Culpin, and Dr. J. A. Hadfield.

Tuesday, Dec. 18th.

GENERAL MEETING OF FELLOWS: at 5 P.M.

Ballot for election to the Fellowship. (Names already circulated.)

Wednesday, Dec. 19th.

HISTORY OF MEDICINE: at 5 P.M.

Papers:

Mr. A. G. T. Fisher: The History of Internal Derangements of the Knee-joints.

Mr. Warren R. Dawson: A Contribution to the History of Egyptian Medicine.

Thursday, Dec. 20th.

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.).

Cases:

Dr. G. Pernet: Cheilitis Glandularis (serpiginosa).

Dr. H. W. Barber: (1) Lichen Nitidus; (2) Tuberculides associated with Rheumatoid Arthritis, and Tubercular Peritonitis; (3) A Case for Diagnosis.

Friday, Dec. 21st.

ELECTRO-THERAPEUTICS: at 8.30 P.M.

Papers:

Dr. Ulysses Williams: Fallacy of the Dropped Colon.

Dr. H. A. Harris: Some Problems in Bone Growth.

Dr. R. W. A. Salmond: The Teaching of Normal Radiography and Radioscopy.

HUNTERIAN SOCIETY.

Monday, Dec. 17th.—Dinner Meeting at Simpson's Restaurant, Cheapside. Discussion on the Influence of Ductless Glands. (1) General: Dr. Langdon Brown; (2) Infancy and Childhood: Dr. Thursfield; (3) Middle- and Old-age: Dr. Leonard Williams; (4) Psychological: Dr. Crichton Miller.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday, Dec. 17th.—10 A.M., Mr. Maingot: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Bishop Harman: Eye Dept.

Tuesday.—12 noon, Dr. Burrell: Chest Cases. 2.30 P.M. Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients.

Wednesday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients.

Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Mr. Simson: Gynæcological Demonstration. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

Friday.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Mr. Endean: Venereal Diseases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

Saturday.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Throat, Nose, and Ear Operations.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

Monday, Dec. 17th.—4.30 P.M., Dr. J. Parkinson: Graphic Methods in Heart Disease.

Wednesday.—4.30 P.M., Concluding Lecture.

THE PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, Oxford-street, W.

Eight Lectures on the Mind and What We Ought to Know About It, at Hamilton House, Mabledon-place, W.C.

Wednesday, Dec. 19th.—6 P.M., Eighth Lecture, Dr. Tredgold: Mental Deficiency.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, Dec. 18th.—4.15 P.M., Dr. J. M. W. Morison: An Introduction to the Study of Radiography.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES.

TUESDAY, Dec. 18th.—3.30 P.M., Prof. Douglas: The Pathology of Pneumonia.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

FRIDAY, Dec. 21st.—(At Boscombe.) Dr. C. E. K. Herapath: Auricular Fibrillation and Flutter.

Appointments.

CAVE, P. N., M.D., B.Ch. Oxf., has been appointed Medical Officer of Health for West Kent.

CONDY, R., M.B., B.Ch. Belf., D.P.H., Assistant Medical Officer of Health for Bury, Lancs.

FORD, A. P., M.R.C.S., L.R.C.P. Lond., D.P.H., Deputy County Medical Officer of Health for Hertfordshire.

FRASER, J. A., M.B., Ch.B. Edin., Assistant Medical Officer at St. Helens.

GAFFIKIN, P. J., M.D., M.Ch. Belf., D.P.H., Medical Officer and Assistant County Medical Officer for the Urban District of Braintree and the Rural Districts of Braintree and Dunmow.

LAWSON, M. A., L.M.S.S.A., Second Medical Officer at St. Mary's Hospital, Plaistow.

LINDSAY, W. J., M.D., B.Ch. Camb., Assistant Surgeon to Out-patients, Royal Eye Hospital, Southwark.

PYE-SMITH, C. D., M.B., B.S. Lond., F.R.C.S. Eng., one of the Medical Referees under the Workmen's Compensation Act for County Court Circuit No. 12, more particularly attached to the Huddersfield County Court.

RANSOM, J. S., Medical Officer and Assistant County Medical Officer for the Urban District of Halstead and the Rural Districts of Halstead and Belchamp.

VLASTO, M., M.B., B.S. Lond., F.R.C.S. Eng., Assistant Surgeon to the Ear, Nose, and Throat Department, West London Hospital.

WILSON, H., M.D., B.S. Lond., Medical Officer of Health for Southwark.

Manchester Royal Infirmary: ROBINSON, G. T., M.B., Ch.B. Manch., House Surgeon; JONES, A. M., M.B., Ch.B. Manch., and APPLETON, J. H., M.B., Ch.B. Manch., House Physicians.

Certifying Surgeons under the Factory and Workshop Acts BARROW, R. M., M.B., B.S. Durh. (Long Sutton); COLLIER, H. E., M.B., Ch.B. Edin. (Redditch).

Vacancies.

For further information refer to the advertisement columns.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—Asst. P. 50 guineas.

Bethnal Green Board of Guardians Hospital. Cambridge-road.—Sen. Asst. M.O. £500.

Birmingham Orthopædic Centre (Ministry of Pensions).—Two Jun. M.O.'s. Each £350.

Bradford Royal Infirmary.—Pathologist. £600.

Bristol General Hospital.—Sen. Res. M.O. £250.

Cancer Hospital, Fulham-road, S.W.—H.S. £100.

Colonial Service, British Guiana.—Three Asst. Govt. M.O.'s. £500.

Dreadnought Hospital, Greenwich.—H.P. £150.

Dudley, Guest Hospital and Dispensary.—H.S. and Asst. H.S.

Dundee Royal Infirmary.—Hon. Asst. Aural S.

Eastbourne, Princess Alice Memorial Hospital.—Res. H.S. £175.

Elizabeth Garrett Anderson Hospital, Euston-road.—Clin. Assts.

Exminster, Devon Mental Hospital.—Third Asst. M.O. £300.

Harefield, Middlesex County Tuberculosis Sanatorium.—Third Asst. Res. M.O. £400.

Hastings, Royal East Sussex Hospital.—Hon. S. and Hon. P.

Hospital for Sick Children, Great Ormond-street, W.C.—Biochemist. £600.

Hull, Victoria Hospital for Sick Children, Park-street.—R.M.O. £100.

London Lock Hospital, 91, Dean-street, W.—Clin. Assistantships.

Loughborough and District General Hospital and Dispensary.—Res. H.S. £175.

Manchester Royal Eye Hospital.—H.S.

Northampton General Hospital.—Hon. Surg. to Ear, Nose, and Throat Department. H.S. £150.

Oldham Royal Infirmary.—Two H.S.'s. Each £200.

Plymouth Royal Eye Infirmary.—Hon. Anæsthetist.

Queen Mary's Hospital for the East End, Stratford, E.—Two H.S.'s. £150.

Royal Army Medical Corps.—Commissions.

Royal Naval Dental Service.—Five Dental Surgeons.

Sheffield Royal Infirmary.—Ophth. H.S. Also Asst. Cas. O. £100.

Tunbridge Wells Eye and Ear Hospital.—Hon. Aural S.

University College Hospital Medical School, W.C.—Radcliffe Crocker Travelling Scholarship in Dermatology. £280.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at St. Helens, Lancs.

Births, Marriages, and Deaths.

BIRTHS.

MOULSON.—On Dec. 7th, at Stone Field, Kidbrook-grove, Blackheath, the wife of Captain Geoffrey Moulson, R.A.M.C., of a daughter.

MARRIAGES.

BLACKWELL—RICE.—On Nov. 28th, at the Minoriten Church, Cologne, Arthur Seal Blackwell, Captain, R.A.M.C., to Mary Georgina Rice, daughter of John Rice, of Fermoy, Ireland.

DEATHS.

BURGESS.—On Dec. 3rd, at Streatham High-road, S.W., William Frederick Richardson Burgess, M.D. Lond., O.B.E., in his 75th year.

SMITH.—On Dec. 6th, at Willow-road, N.W., of pneumonia, John B. Smith, M.A., M.B., Ch.B., aged 74.

TREVES.—On Dec. 7th, of peritonitis, in a nursing home at Lausanne, after a brief illness, Sir Frederick Treves, Bart., G.C.V.O., C.B., aged 70.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE "MINTITE" PATENT FINISH HOT-WATER BOTTLE.—With reference to the notice of the "Mintite" patent finish hot-water bottle in THE LANCET of Sept. 15th, we are asked to state that manufacturing licensees are attaching a two years' guarantee to these productions. Supplies are now obtainable from many of the principal distributors, including Boots Pure Drug Co., Ltd., and the London Rubber Company's various branches.

Notes, Comments, and Abstracts.

THE LIFE AND TIMES OF WILLIAM CLIFT.[1]

BY SIR ARTHUR KEITH, M.D., LL.D. ABERD.,
F.R.C.S. ENG., F.R.S.,
CONSERVATOR OF THE MUSEUM OF THE ROYAL COLLEGE SURGEONS OF ENGLAND.

[Sir Arthur Keith began by recalling the fact that William Clift, first conservator of the Museum of the Royal College of Surgeons of England, arrived at the house of John Hunter in Leicester-square on Feb. 14th, 1792, his own seventeenth birthday and the sixty-third birthday of John Hunter. It was said that he carried with him certain indentures wherein Hunter had undertaken to teach him "in his best manner," to draw, write, and dissect. The bond between the two men was soon to be broken; Clift had only served his master for 20 months when the catastrophe at St. George's Hospital left him stranded in Hunter's derelict museum. Sir Arthur Keith continued in the following sense:—]

For fifty years William Clift was the honest steward of the great collection which Hunter left behind and the undaunted upholder of his name and fame. There was more than a mere coincidence of birthdays to link these two men together; as Clift aged those who had known Hunter saw in him a remarkable physical likeness to the master. Both were small active men; Hunter's height was only 5 ft. 2 in. To those who insinuated that this likeness was due to more than a coincidence Clift would reply: "If I thought such were true there is not a duke in London I would touch my hat to."

Parentage and Upbringing.

Clift's birthplace was a flour-mill at Bodmin, swept away when the London and South-Western Railway built its station about a mile to the west of the centre of the town. In 1775, when his youngest son William was born, the affairs of the miller, Robert Clift, were hastening from bad to worse; he had to leave the mill, and three years later died in Bodmin at the age of 58, leaving his wife, Joanna Courts, and his amily in poverty. The widow and daughters earned a precarious livelihood by carding and spinning wool in the winter and by working in the fields in other seasons—each member earning from 4*d*. to 6*d*. a day. In 1783, when Clift was 8 years of age, his mother died, and he entered the servfce of Mr. George King, a nurseryman at Bodmin, at 4*d*. a day. Two or three years later, in a drunken fit, King chased his apprentice from the nursery; Clift drew a graphic caricature of the incident, which secured his discharge from the nurseryman's employ. He tried to enlist, and then found service in Bodmin with a farmer and corn-merchant. Here he might have remained, for he had ingrained within him that spirit of timidity and tendency to self-criticism which make men eek for service rather than for command, but often makes uch men the hardest judges of their fellows; but at that ime the Priory near Bodmin Church was occupied by Major Gilbert, whose wife had been at school with Anne Home, John Hunter's wife. They knew at the Priory that Hunter's draughtsman, amanuensis and assistant in the museum, William Bell, had accepted a surgeoncy in Sumatra, and for three years Hunter had found no one fit to succeed him; upon Mrs. Gilbert's recommendation Clift was suddenly transported from a poverty-stricken home in Cornwall to ne of the most remarkable households which London has ever seen.

Hunter's House and Museum.

The household in which young Clift now found himself n inmate stretched from Leicester-square eastwards to Castle-street—now converted into Charing Cross-road. Our intimate knowledge of the shape and size of the establishment we owe to Clift; 40 years after he first entered it, he sat down late at night and drew a ground plan of Hunter's ouse. The property, which Hunter had acquired in 1783, was built on a long narrow strip of ground only 30 feet wide. At the Castle-street end in place of stables was a roomy dwelling where Hunter's five house-pupils had quarters. Here, too, was the dissecting-room, and quarters for Robert Haynes who looked after it, and the lecture-room; here, too, was Clift's abode. In the garden or yard stretching from the one house to the other Hunter had erected a building with an inside measurement 51 feet long and 28 feet wide. The ground floor was divided so as to serve as a reception-room towards the Leicester-square end and a lecture-room towards the Castle-street end. The lofty upper floor of this building served as a museum; round it ran a gallery, on the shelves of which stood Hunter's wonderful collection of physiological preparations—the part of the museum which became Clift's special pride. From the gallery a fossil- or cabinet-room opened off. Between the museum and the house on Leicester-square (No. 28) there was room for the building in which Hunter kept his collection of drawings and prints, and where his artist worked.

Clift found himself a member of a very large establishment. If we include the Earl's Court building, which was really an experimental station run in connexion with Leicester-square, there were 50 people depending on Hunter for their sustenance or pay. For Mrs. Hunter and for Miss Hunter (afterwards Lady Campbell) Clift acquired and retained an unbounded respect and devotion. With regard to the professional activities of the house, it was early in the morning before the professional round commenced, and late in the evening and night after it was finished, that William Clift had his busy time. He had to fetch, carry, inject, draw, display structures with a scalpel, write fair his master's rough notes of dissections, of clinical observations, and of new thoughts and ideas which had occurred in the course of the day's round. During the 30 years Hunter had been researching and building up his museum the subjects of his inquiry were ever broadening, new accounts had to be continually opened in his scientific ledgers, and old general accounts distributed under a series of new headings. Hunter's museum was but a concrete illustration of the contents of his manuscripts.

Mr. Everard Home.

An important inmate of Hunter's household when Clift entered it was Everard Home, brother of Mrs. Hunter and assistant surgeon to St. George's Hospital. Hunter's health had been failing for some years; his arteries had become hard and his heart filled them with difficulty. He had need of assistance; Home lived in and helped him in his operations, did the night work, read his lectures in the class-room in the Castle-street establishment and looked after the pupils. Home was a man of no mean ability; he was recognised by his contemporaries as an excellent practical surgeon and a clear-headed man of business. He was ambitious, particularly for scientific eminence; if only his discoveries had possessed the value he placed on them his career would have been one of unqualified success. His attributes must be borne in mind if we are to understand the relationship which became established between Home and Clift, ending in the tragedy of the manuscripts.

Hunter's Death.

In the spring of 1793 war had broken out with France, and Hunter was busy with his duties to the army. The income of the house was large but the expenditure was lavish. Hunter, to get a supply of ready cash, had been borrowing; he had to accommodate urgent creditors, and Clift had no pay; but Hunter, "probably to avoid having a footman in green found writing with him in his study," provided him with new clothes. With Hunter's death on Oct. 16th, 1793, the great Leicester-square establishment came down with a crash. Mrs. Hunter had to leave the house and for a time her drawing-room was occupied by lodgers. The whole staff was dismissed save two: Mrs. Adams, the housekeeper in Castle-street, and William Clift, who was at first allowed 1*s*. a day board wages to look after the museum—an allowance afterwards commuted to £21 a year. Home sought to continue Hunter's lectures which were given under the museum, but after two years he gave up, for he was an indifferent teacher. Clift attended his second course and tried to take notes from him. The care of the museum devolved on Hunter's executors, Home and Matthew Baillie, both young men struggling for practice. Home was the senior and acting executor. Immediately after Hunter's death he became most prolific in the output of papers—both scientific and surgical. He stepped into Hunter's shoes, attempting to use the museum and Clift's services just as Hunter had done. In the intervals between Home's visits Clift studied the contents of the museum and particularly Hunter's manuscripts; he copied for his own use nearly half of Hunter's writings. During the seven years which followed Hunter's death Clift's salary was £21 per annum. In 1799, when he was 25, he married; he added to his meagre income by copying manuscripts and by drawing for Baillie, whose "Morbid Anatomy" he illustrated, for Monro of Edinburgh, Hey of Leeds, Sir Joseph Banks, and many others. Home got off cheaply; all his drawings, dissections, inquiries, and odd jobs were done for a Christmas box of five guineas, but in 1800, when the museum had passed into the keeping of the College of Surgeons, a new arrangement had to be instituted. Home promised, and Clift expected, that his salary as conservator under the College would be fixed at £100 per annum, but £80 was the sum actually fixed upon. Home undertook to make the deficiency good by purchasing every Christmas £21 worth of 3 per cent. stock and placing it to

---

[1] An Abstract of the Vicary Lecture delivered in the Theatre of the Royal College of Surgeons, on Dec. 7th, 1923.

Clift's credit until the capital produced an annual income of £21, a promise which he kept—and in later years claimed thereby to have been Clift's magnificent patron. For this sum Clift supplied his patron with the splendid drawings which adorn a hundred papers published by Home in the Philosophical Transactions, besides those in the great volumes on comparative anatomy; he also carried out investigations and experiments for Home year after year, looked after his papers, and was always at his beck and call.

In 1799, just before the museum passed into the care of the College, Home ordered the manuscripts to be removed from Castle-street. Clift loaded a cart with them and conveyed them to Home's house in Sackville-street.

The Board of Curators.

When the College of Surgeons took over the care of Hunter's museum, the managing body, then known as the Court of Assistants, appointed seven of its number to form a Board of Curators to look after the new charge. In the summer of 1800 the Board met at Castle-street and amongst their instructions to their newly appointed conservator were clauses instructing him to live and sleep in the museum and to accept no gratuities from visitors. Home, although not yet a member of the Court of Assistants, was present at this early meeting and volunteered, with the aid of the conservator, to prepare a complete catalogue of the collection. By 1803 Home had been elected to the Court of Assistants, and was naturally appointed a member of the Board of Curators, thus acquiring a dominant influence in the affairs of the museum. He set Clift to compile catalogues of all sections of Hunter's collection, these catalogues being mere lists of contents, but drawn up with great care and written into folio volumes with meticulous accuracy. Home was too busy looking after his hospital, his practice, and the output of scientific and professional papers to take any part in the work of cataloguing.

The New Museum.

In the summer of 1805 the trustees appointed by Parliament to see that the College of Surgeons carried out the conditions attached to its trust, met for the first time. The trustees inquired about catalogues and about lectures and were told that the College had already spent £2547 on the collection, and that, as the lease of the Castle-street museum was almost up, the College had bought for £4600 Mr. Jenner's house (No. 42), next door to the College House (No. 41), on the south side of Lincoln's Inn Fields, as the site of a new museum. The garden of No. 42 was the actual site on which the new museum was to be built. In the spring and summer of 1806 Clift moved the Hunterian collection from Castle-street and stowed it safely away in the rooms of the museum house, until the new building was erected behind; it was not until 1813 that the museum was finished and opened to visitors. The conservator's chief duty was to conduct visitors round the museum twice daily and explain its contents to them. Of this daily duty Clift never tired.

Meanwhile Everard Home, in 1808, had been appointed Serjeant Surgeon to the King; he was elected in 1811 to give the first course of lectures on Comparative Anatomy. In 1813, having become Master of the College and a baronet, he agreed to publish these lectures and persuaded the Board of Curators to spend College money on their gratis distribution.

The Board of Trustees kept urging the need of supplying proper catalogues for the museum. In 1816 Home claimed the duty and honour of preparing these catalogues, made the conservator rearrange an important section of the museum, and wrote a short guide or synopsis for this section. In 1817 he resigned from the Board of Curators and became elected to the more influential Board of Trustees. He lost no prestige with the Court of Assistants, for in 1821, when this body became known as the Council of the College, they elected him to be their first president.

Burning of the Manuscripts.

In 1823 Home placed certain fossil bones, discovered in caverns near Plymouth, at Clift's disposal. Clift described them in a paper read before the Royal Society; Home championed his election to the Society, and on May 6th, 1823, Clift became F.R.S. The relationship between Home and Clift at this time, as shown in letters, was still that of patron and servant. In July, 1823, Home informed Clift that on the night before the conversation firemen had forced their way into his house because his chimney was on fire; the damage had been done while burning Hunter's papers. "You don't mean," said Clift to the baronet, "you have burned Hunter's manuscripts?" Home said he had done as he said, to which Clift relates that he made this reply: "Then, you may as well set fire to the museum too." Apparently nothing more happened at the time; in November Home was still addressing the conservator as "My dear Clift." At this juncture, August, 1823, Home's co-executor, Dr. Matthew Baillie, died without knowing the fate which had overtaken Hunter's manuscripts.

William Clift Turns on Home.

Clift took an early opportunity of telling the chairman of the Board of Curators, Sir William Blizard, what had happened. Nothing was done then; the first step was taken in February, 1824, when Clift was called in by the Board of Curators, which included Cline, Norris, Astley Cooper, Abernethy (Clift's particular friend), Anthony Carlisle, and Lynn. Clift enumerated the manuscripts, and rightly held them to have been an intrinsic part of Hunter's collection and essential for the preparation of a real catalogue. A month later the Board requested Sir Everard to hand over the manuscripts which they had just learned were, or ought to be, in his possession. Home replied that he had destroyed the manuscripts because they were unfinished and unfit for the public eye; further, he had extracted from them and published all that was essential, and finally, that he had closed his 30 years' executorship by destroying them, which, so he wrote, Hunter had instructed him to do! In the meantime, Clift had learned that there were still some Hunterian manuscripts in existence. To a further demand made by the Board of Curators Home replied declining further correspondence with the Board. The Curators then carried the matter to the higher authority, the Board of Trustees. In May, 1824, the trustees held a special meeting—ostensibly to consider the preparation of proper catalogues for the museum. Home, on being questioned, stated that he had destroyed the manuscripts as a duty, but that he was willing to offer all possible help in the preparation of catalogues. He did help to some extent, for to the next two meetings of the trustees he sent sealed packets which were found to contain series of Hunter's own descriptions of post-mortem examination of cases.

Home died in August, 1832. Clift, in his diary, alleged that the glowing eulogium of Home pronounced at the Royal Society on that occasion was written by the deceased gentleman himself! Six weeks later Home's son handed to Robert Keate, ex-president of the College, a bundle which was found to contain Hunter's famous folio volume on "Vegetation" and also ten separate manuscript fasciculi. Seven years later young Home produced another sealed packet, which contained Hunter's folio volume on "Fossils," wherein we learn that Hunter had been thinking 40 years ahead of the geologists of his time. The open page in the Reynolds's portrait tells us that he was 70 years ahead of his contemporary anthropologists. No further discovery of Hunterian MS. had to be reported.

Clift supposed, and his supposition has usually been accepted, that Home's motive in committing his act of vandalism was to keep the public from discovering how many discoveries and observations he had stolen from Hunter's manuscripts. I do not believe this to be the true reason. In his correspondence with the Board of Curators and trustees he not only admitted but claimed as a merit that he had extracted and published all that was of value in Hunter's manuscripts before burning them! Home was vain, ambitious, extremely conventional and orthodox in his beliefs; Hunter was heterodox, and in his writings were statements which, if published, would have made the hair of the orthodox stand on end. Home declared they were unfit for the public eye, and we may safely infer that he counted Hunter as in error when he was heterodox. Home himself saw the dire fate which overwhelmed William Lawrence when he spoke out his true thoughts concerning man's relationship to animals in the theatre of the College in 1816. Home thought he was doing his old and wayward master a true service when he destroyed his unpublished manuscripts.

Conclusion.

In 1827 Richard Owen, only 23 years of age, came to Clift's rescue and showed all the world how a catalogue of a great collection of comparative anatomy should be written. There is no space in which to tell how James Paget came in 1842 to render a similar service for the pathological side of the museum. Richard Owen married Miss Clift; his father-in-law's self-confidence declined as his own grew. Clift's nerve was sapped by the death by accident, in 1832, of his son, whom he had hoped to see as his successor. In 1842 Clift was informed that his salary of £400 per annum was to continue for the rest of his life, that he was to move out of the conservator's quarters in the College, and that Owen was to move in. He retired to Stanhope Cottage, near Mornington-crescent, off the Hampstead-road, and died there in June, 1849, in his seventy-fifth year. His wife died six weeks before him. Richard Owen inscribed on Clift's tomb in Highgate Cemetery: "He carried a child-like simplicity and singlemindedness to the close of a long and honoured career."

CIRCULATION AND ASSIMILATION IN PLANTS.

Sir Jagadis Chunder Bose, F.R.S., director of the Bose Institute, Calcutta, delivered an occasional address before the Royal Society of Medicine on Dec. 6th. The substance of his remarks was as follows :—

The movement of sap inside the tree is invisible, and no accurate means have hitherto been available for the measurement of the normal rate of ascent of sap and how that rate is affected by changes of the environment. I have overcome the difficulty by devising three different types of apparatus by which the normal rate and its modification is determined with the highest accuracy. Strasburger from his experiments imagined that poisoning did not affect the ascent of sap ; hence he inferred that the movement of sap cannot be due to the physiological action of living cells. This view, which found general acceptance, had the most disastrous effect on investigation of this intricate problem. My results completely disprove Strasburger's conclusion. The records obtained by my apparatus show that a complete arrest of ascent takes place under the action of poison. Experiments prove that a definite active tissue extends throughout the length of the tree, the cellular pulsations of which in regular sequence cause by their pumping action the propulsion of sap. In the animal the circulation is maintained by the pumping action of the throbbing heart. Since the mechanism for the movement of sap is essentially similar, the tree may be regarded as possessing an elongated " heart."

The " Heart " of a Plant.

The effects of various agents on the " heart-beats " of the tree and of the animal exhibit most astonishing similarities, of which I shall mention only a few instances. In the case of the animal it is well known that the frequency of heart-beat is quickened under a rise and slowed down under a fall of temperature, till at a sufficiently low temperature the rhythmic activity becomes arrested. Under certain abnormal conditions when the beating of the animal heart is arrested it can be renewed by adequate stimulation. Certain stimulants cause a great enhancement of the pulsatory activity while poisons arrest it. Results in every way parallel to these are observed in the cellular pulsation of the tree. Rise of temperature increasing the pulsatory activity enhances the rate of ascensional movement of the sap. Lowering of temperature, on the other hand, causes a depression of the rate, till at a critical temperature the ascent becomes arrested. A slight rise of temperature above the critical point, however, renews the ascent. Under condition of sub-tonicity the cellular activity and the resulting movement of sap become arrested. Stimulus is now found to revive the activity and renew the ascent. Very striking results are produced by the action of anæsthetics which in a small dose acts as a stimulant. A small dose of ether is thus found to enhance the cellular pulsation and cause a great increase in the rate of ascent. Chloroform causes a preliminary enhancement followed by arrest caused by the toxic effect of a large dose.

The Electric Probe for Record of the Internal Pulsation.

My experiments proved that the movement of sap is maintained by the pulsating activity of certain cells. The next problem was the localisation of the pulsating layer, and to obtain an actual record of the individual pulsation and watch its responsive variations under drugs and other agents. For this we have to get access to the smallest unit of life, the individual cell. But the pulsatory movement of a cell is ultra-microscopic and its detection may well appear to be beyond the range of possibility. This has, however, been accomplished by my electric probe in circuit with a recording galvanometer. The probe is gradually introduced across the tree, its tip thus coming in contact with successive layers of cells. The record thus obtained is thrown on the screen, from which it will be seen that the galvanometer remained quiescent till the probe came in contact with the active layer, whose throbbing pulsations gave rise to corresponding electric pulsations recorded by the galvanometer. In dicotyledenous plants it is the inner layer of cortex which functions as the organ for the propulsion of sap. Moreover, any agent which quickens or arrests the heart-beat of the animal is also found to enhance or inhibit the electric heart-beat of the tree. The fluctuations of the life-activity in the interior of the tree are revealed by the waxing and waning of its pulse-records. We are now in a position to realise the essential similarity of physiological mechanism in the maintenance of circulation in the plant and in the animal.

Assimilation in Plants.

It is through these incessant internal activities that the tree is enabled to raise large quantities of water to a height sometimes as great as 450 feet, as in the giant eucalyptus. The energy for doing this work is in the breakdown of complex chemical substances in internal combustion or respiration. The phenomenon of CO_2 assimilation in plants is of great theoretical interest as an example of the simplest type of assimilation. In normal photosynthesis a certain volume of CO_2 is absorbed and an equal volume of oxygen evolved. Photosynthetic activity may therefore be measured from the rate of absorption of CO_2 or of evolution of oxygen. I devised a photosynthetic recorder, by which the evolution of pure oxygen becomes automatically recorded. The method is automatic and so extremely sensitive that it is possible to measure photosynthetic deposit of carbohydrate as minute as a millionth of a gramme. The extreme sensitiveness and accuracy of the new method has led to the discovery of several important phenomena which otherwise would have been impossible. Stimulation is found to produce characteristic modification in the assimilation. The immediate and concrete demonstration of the effect of minute traces of chemicals—e.g., on assimilation of plants—is of special interest, since it enables us to understand the effects of ultra-measurable quantities of vitamins on general assimilation and of hormones on physiological reaction.

The " Nerves " of a Plant.

The plant is a multicellular organ and hence necessity arises for intercommunication and interaction between more or less distant organs ; this is accomplished in two different ways ; the first is exemplified by the hydraulic convection of liquids carrying chemical substances in solution such as occurs in the circulation of sap. The second mode of intercommunication is the conduction of excitatory change along certain tissues in the plant which function as nerves.

The ultimate result of investigations such as these and others which I have been able to complete is the establishment of the important generalisation of the unity of physiological mechanism in all life. For we find in the plant and in the animal similar contractile movement under stimulus, similar reaction under particular drugs, similar cell-to-cell propagation of pulsatory movement, similar circulation of fluid by pumping action, similar nervous mechanism for the transmission of excitation, and similar reflex movements at the distant effector. The simpler type of plant organisation offers an unique advantage in investigation, the pursuit of which will no doubt lead to the solution of many perplexing problems of animal life.

THE GEOGRAPHICAL METHOD.

Dr. Saleeby has invented a new method of medical research. " Being without patients and laboratories," he writes,[1] " I applied the geographical method." Put more plainly this means that Dr. Saleeby, being without clinical experience (as he himself admits more than once in this book) and without more than the rudiments of pathological knowledge, travels about visiting hospitals, sanatoriums, and laboratories, and picks up stray information here and there. Although Dr. Saleeby describes himself as a life-long student and worshipper of light, it was only two years ago that he discovered that other people had discovered the value of heliotherapy in tuberculosis. Under his very nose, so to speak, Sir Henry Gauvain had practised heliotherapy in this country, and in the same memorable year that the veil of ignorance was lifted from the eyes of Dr. Saleeby by a visit to Leysin, Sir Henry Gauvain published in our columns a paper in which he emphasised the value of heliotherapy as an important adjuvant to the treatment of tuberculosis, but not as a cure for tuberculosis. It is one of the advantages of the geographical method that it enables Dr. Saleeby to describe himself as " the person most responsible for the arrival of the sun cure in England." He is an interesting example of what the psychologists call " projection." He is under the impression that the routine treatment of surgical tuberculosis is by operation, and he projects his own ignorance on to the medical profession. He does not realise that at Leysin, as anywhere else, the principle underlying the treatment is largely rest of the affected part. " The patient is cured by the action of light on the skin " (p. 67). He himself has realised for the first time that the resistance of the patient to the infection is an important factor in the treatment of tuberculosis, and writes as though bacteriologists generally were in the same position. We get this picture of Dr. Saleeby's conceptions before his journey to Leysin : " Is it stupid or, at most, is it merely half and not whole-witted to consider only the toxicity of the guest and not the readiness to be poisoned of the host ? The bacteriologist with one eye looking at the bacteria through the microscope, and *the other shut* is the type and warning of the danger which many of us have not escaped " (p. 39).

From his wanderings Dr. Saleeby returns to London, and now—behold the results of the geographical method which dispenses with patients and laboratories. It has taught him that sunlight cures and prevents tuberculosis. He is aware that this teaching will meet with opposition, but being a practised controversialist he undermines the position of his opponents, saying: "Very formidable vested interests in the knife and the bottle will have to be combated" (p. 105). He demands an inquiry into the physiological action of light, evidently ignorant of the not inconsiderable literature on the subject which already exists. All this set forth in "words of learned length and thundering sound impressed the gazing rustics ranged around." Coincidently the Medical Research Council appointed a committee to investigate this subject. Dr. Saleeby predicts that "from the date of the appointment of the Special Committee, under the chairmanship of Sir William Bayliss, a new chapter in clinical and preventive medicine will be seen to begin."

---

[1] Sunlight and Health. By C. W. Saleeby, M.D. London: Nisbet and Co. 1923. Pp. 178. 5s.

The chapters in this book are loosely strung together and appear to have been taken from popular essays and lectures, although that is not clearly stated. In any case the writing is not that of a clinician or a scientist who pledges his reputation for the statements he makes, but that of a journalist whose gift of popular exposition, exercised doubtless with a sincere belief in the truth of what he writes, nevertheless appeals most to the reader who prefers a well-turned phrase to accuracy and to whom a stunt is the breath of life. No responsible person acquainted with the complexity of the problem involved in the ætiology of tuberculosis would be tempted even by the alliterative ring of the word to call it "a disease of darkness" and classify it with rickets. Sir Henry Gauvain states that light by itself does not cure tuberculosis. He looks upon it as an important adjuvant in the treatment. But then he has patients, and is therefore not a true disciple of the geographical method. Surely Sir William Bayliss, who contributes a preface to this book, has not accepted the geographical method as a trustworthy guide? He certainly commits himself to the statement that light can cure and prevent tuberculosis.

Now, light is a powerful weapon in our therapeutic armoury. But it is doing heliotherapy an ill-service to treat light as a patent medicine, and make exaggerated and foolish claims for it. And it is not only foolish, but mischievous to teach that tuberculosis is a disease of darkness and can be cured by light. We associate ourselves with the statement of Dr. F. E. Wynne, medical officer of health in Sheffield, which Dr. Saleeby holds up to ridicule in his book: "No one who has the true interests of our tuberculous population at heart can fail to regret Dr. Saleeby's suggestion that sunshine can cure tuberculosis."

PUBLIC HEALTH IN INDIA.

Hospital and Prison Administration in the United Provinces.

The Civil Hospitals and Dispensaries in the United Provinces numbered 661 at the beginning of 1921; six were closed and five new institutions opened during the year. The patients treated (5,718,724) showed a decrease of 70,207 on the figures for 1920, but were more numerous than in any of the five years preceding. The cases of cholera and dysentery numbered 11,372 and 127,142 respectively, both much in excess of those in 1920; malaria (1,242,208 cases), rheumatism, and venereal diseases showed a considerable decrease. Plague caused 24,009 deaths in the province, a slight decrease on the mortality (24,872) of the previous year; only 16 cases were admitted to hospital, of whom six died. The number of inoculations performed was 14,906, compared with 36,453 in 1920, efforts having been concentrated on an anti-rat campaign. Colonel J. K. Close, I.M.S., Inspector-General of Civil Hospitals for the province, notes in his report [1] that the system of charging patients able to pay has continued to act satisfactorily, and that no complaints have been received as to charges made; the total sum realised was Rs.32,645.

In his report on the administration of the jails [1] in the United Provinces, for 1921, Lieut.-Colonel J. M. Woolley, I.M.S., Inspector-General of Prisons for the province, notes that, on the occasion of the visit of H.R.H. the Prince of Wales, 3804 convicts were released, and that a considerable number were given remission of sentences; but, on account of the admission of a large number of political prisoners, very heavy extra work had been thrown on the department; moreover, the unhealthy conditions during the autumn and widespread epidemic diseases, following a period of intense heat, had a prejudicial effect on the health of the prisoners. The total number of prisoners that passed through the jails during the year was 109,130, as compared with 103,366 in the previous year; the daily average present being 25,164, an increase of 356 over the jail population in 1920. Transportation convicts are now detained in the Central Prisons, consequent on the abolition of transportation; a proposal for a special jail for this class of prisoners is now under consideration. As regards the health of the prisoners, the admissions to hospital were 607·8, the average daily sick 23·5, and the deaths 21·4 per 1000, as compared with 588·6, 22·6, and 17·0 in the previous year; the increase in mortality was chiefly due to pulmonary tuberculosis (79 deaths, compared with 64 in 1920), pneumonia (76 against 63), and heat-stroke (26). This last mortality is unusually high; it occurred throughout the province, mostly in mid-June; in many jails hard labour was curtailed in the middle of the day. There were 47 admissions to hospital for cholera, of which 22 ended fatally. Of the 42,827 convicts discharged during the year no less than 65·83 per cent. had gained weight, and only 9·58 per cent. lost weight. Lieut.-Colonel Woolley notes that "the year has been remarkable for the large number of political prisoners admitted . . . under the Criminal Law Amendment Act. . . . The spirit of lawlessness was noticeable even among ordinary prisoners, and the officials dealt with it firmly and with much tact and patience."

WHAT IS A MOSQUITO?

There has been a widespread idea that a mosquito is a particular species of insect inhabiting the tropics. And this harmful idea the third edition of Mr. F. W. Edwards's admirable little pamphlet on "Mosquitoes and their Relation to Disease" will greatly help to dispel. The pamphlet is No. 4 of an Economic Series issued by the trustees of the British Museum (Natural History) and is designed to be of use to those who visit the museum as well as to a wider public whose safety lies in a knowledge of the life-history, habits, and control of the mosquito. A short bibliography is attached to the pamphlet, the price of which is 4*d*.

THE KIND OF NURSE SHE WANTS.

To the Editor of The Lancet.

Sir,—It is pleasing to know that "A Middle-class Patient" agrees that nurses are entitled to a high standard of comfort. She need not have worried about extra accommodation, as there are visiting nurses in London and other towns in the provinces who would attend to her physical needs once or twice daily for a very moderate fee. These nurses are well trained, and work under the direction of the family practitioner. The patient will find in the Telephone Buff Book the names and addresses of over 200 visiting nurses in London. I am, Sir, yours faithfully,

Christine S. Crawford,
Visiting Nurse.

London, Dec. 8th, 1923.

CROSSED KNEES AND VARICOSE VEINS.

To the Editor of The Lancet.

Sir,—I suggest that one of the earliest factors operating in the causation of varicose veins of the legs is the habit of crossing one knee over the other. I can conceive no position better calculated to retard the normal flow of blood in the superficial veins of the lower extremities. The pressure catches the internal saphenous vein where it passes slightly behind the knee-joint, while the external vein is blocked by the pressure in the popliteal space. No wonder their valves become disorganised in the course of years.

I am, Sir, yours faithfully,

Henry Geo. Dixon, M.R.C.S., &c.

City-road, London, E.C., Dec. 3rd, 1923.

*** The thesis would be strengthened by some evidence that venous compression does actually take place.—Ed. L.

A HANDY TABLE OF FOOD VALUES.

Insulin, however useful it may be, does not, of course, do away with the necessity for dietetic restriction. After the initial fast it is usual to place the diabetic patient upon a diet of about 12 calories to each pound of body-weight, with definite proportions of protein and carbohydrate, fat then being added to make up the proposed total. To carry this out with success requires accurate knowledge of foodstuffs and their caloric values, and Dr. Sinclair Miller and Dr. F. B. Smith, of the Clinical Laboratory, Harrogate, have compiled some useful Tables of Food Values to assist in securing accurate dietetic control. It is obviously desirable to make a patient's diet as variable and attractive as possible within the limits prescribed, and by the use of these tables alternative diets of fixed food value can be arranged in considerable variety. Three tables are given dealing with foods containing chiefly carbohydrates, proteins, and fats respectively, arranged in alphabetical order. In each case the content of the foodstuff in grammes of carbohydrate, protein, and fat, with the total calories, is immediately to be found. The price is 1s., and the publishers Messrs R. R. Browne and Co., Belfast.

An Address
ON THE
CHRONIC DYSPEPSIAS OF WOMEN.

Delivered at the Annual Meeting of the Norfolk and Norwich Medico-Chirurgical Society.

BY A. J. WALTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON, LONDON HOSPITAL.

IT is becoming more and more evident that the estimation of surgical skill is to be based rather upon the surgeon's knowledge of the type of case on which to operate than upon his method of operating. Almost anyone can, with a little practice, become sufficiently expert to perform complicated operations, but only those who have had wide experience and training can determine when such an operation should be carried out. Nearly all modern disasters of surgery are due not so much to errors of technique as to the fact that a certain operation is performed on the wrong type of patient. If asked what is the type of case which to-day gives me the greatest difficulty in making up my mind whether or not to operate, I have a ready answer. The greater part of my consulting practice is made up of patients, often women, who are suffering from chronic dyspepsia, generally of many years standing, the symptoms of which do not actually fit in with those of any organic disease of the stomach, duodenum, gall-bladder, or pancreas, and yet superficially resemble these conditions. They have also often had a long course of medical treatment with little or no benefit. Two questions at once present themselves: Are such patients suffering from an organic lesion as well as their chronic dyspepsia; and if it be certain that they have no organic lesion, should they be treated by operation? These questions are to-day enormously exercising the medical profession; large numbers of these cases are seen by all surgeons who are doing much work on the abdomen. As I have been for many years devoting considerable attention to this question, and have had an opportunity of watching the results of many forms of treatment in a well-equipped follow-up department, I have arrived at certain conclusions here published. These conclusions, however, are not yet fixed, and it is quite possible that in a few years' time they may alter considerably.

A TYPICAL CASE OF CHRONIC DYSPEPSIA.

I will first describe a typical example of such a case, one which will be widely recognised. The patient, usually a woman between the ages of 20 and 30, seeks advice for long-continued dyspepsia, which, on careful questioning, is found to date back to between the ages of 12 and 15. She will usually state that this has been continuous, but often there are intervals of two or three days' relative freedom. Even during these periods she will have to exercise care in her diet or the symptoms will return. In later years they have progressed and become much more severe, until she is no longer able to lead a normal life, to take a natural diet, or to perform her usual duties. Her chief complaint will be of severe pain, usually commencing in the epigastrium and passing round to the back. It is increased by food and usually comes on shortly after the ingestion of a meal, so that not only has she modified her diet considerably, but in many cases has cut it down to a minimum and has therefore lost considerable weight. As a general rule the pain is increased by exercise, is worse at the end of the day, and is sometimes relieved by lying down. In the more severe attacks it is associated with frequent vomiting, and the patient will not uncommonly state that she vomits everything that she takes; this is manifestly an exaggeration, for the patient may be in good condition, not showing the evidences of profound wasting and collapse which would be the accompaniment of such symptoms. The appetite is poor, and, in fact, the patient frequently has an entire distaste for food. At times there may be attacks of sharp hæmatemesis with the vomiting, which will considerably strengthen the belief that a gastric ulcer is present. Constipation is usually a marked feature, so that the majority of such patients habitually take aperients. Physical examination will reveal certain characteristics which will help in the diagnosis.

PATHOLOGY OF THE CONDITION.

Although such is a very common example of the type of case under discussion there are others in whom the symptoms differ considerably, so that the resemblance will not be so close a one to that of gastric ulcer as to that of chronic appendicitis or to gall-stones. The severity of the pain, the long-continued symptoms, and the general deterioration in the health of these patients has in the past led many of them to be subjected to operative treatment, and to the astonishment of the surgeons no definite organic lesion has been discovered. The enormous amount of work which has recently been done upon this type of case has now, however, shown very clearly that there is a very definite pathology. This is widespread in its effects and is shown by (1) localised abnormalities in the intestinal tract, (2) changes in the general body structure, (3) alterations in the nervous system. It must be clearly understood, however, that the extent of these different changes varies very considerably, and only by a careful consideration of them all can one arrive at a correct diagnosis. I propose very briefly to consider them one by one.

LOCALISED CHANGES IN THE INTESTINAL TRACT.

Although perhaps not of the greatest importance, the presence of localised changes in the intestinal tract gives rise to the symptoms we are considering.

FIG. 1.

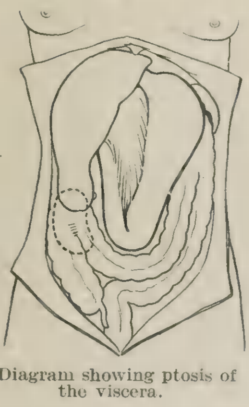

Diagram showing ptosis of the viscera.

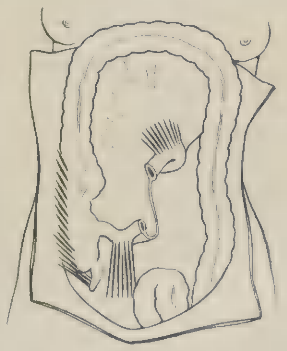
FIG. 2.

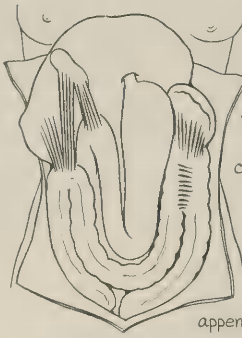


Lane's kink, Jackson's membrane, and the mesocolic fold.

The first most constant change is one of abnormal mobility and general dropping of the viscera. (Fig. 1.) The stomach and transverse colon are low, the cæcum is displaced downwards and freely movable and has a long mesentery. The right kidney passes down with the cæcum, to which it is generally adherent. The liver is low and rotates to the right, and often shows secondary changes in its contour. The uterus is retroverted and prolapsed, and the coils of the small intestine are sunk low into the pelvis. Although both increased mobility and ptosis are always found in patients with these symptoms, the former may be unexpectedly found at an operation for some other condition, and may give rise to no symptoms; even a profound degree of ptosis may be present and cause the patient no inconvenience. I have seen a large number of cases, some of them indeed my own personal friends, upon whom an operation for some acute condition such as appendicitis disclosed a freely mobile and low cæcum and transverse colon, and yet in after-life no further symptoms have developed.

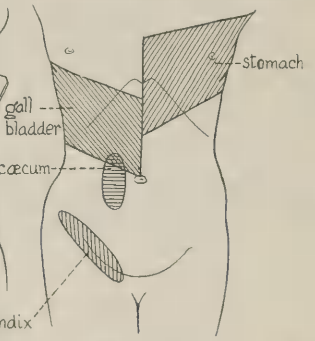
The second change is the presence of abnormal bands and membranes, usually most marked in the situation where the long mesenteries are evident. The nature of these membranes and bands are shown diagrammatically in the illustrations I present. There is a thin membranous sheet (usually described as Jackson's membrane) passing from the outer side of the cæcum and ascending colon to the right parietal wall and often upwards to the liver. There is a band on the under surface of the mesentery of the lower ileum trying this latter structure, in a small part of its course, down to the posterior abdominal wall and causing a kink of the ileum known as Lane's kink. (Fig. 2.) There is a membranous band, passing from the under surface of the mesocolon to the first few inches of the jejunum, known as the mesocolic fold. From the gall-bladder run membranes passing to the duodenum and to the hepatic flexure, known respectively as the cystico-duodenal and cystico-colic folds. There are thickened bands passing from the splenic flexure to the spleen and across from the distal end of the transverse colon to the first part of the descending colon, binding these two structures together and kinking them. (Fig. 3.) There is yet a further membrane, known as Toldt's membrane, which lies on the outer side of the pelvic colon and binds it down to the left iliac fossa.

Fig. 3.



The cystico-colic and duodenal folds and Payr's membrane.

Fig. 4.



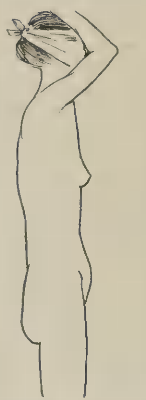
Areas of hyperæsthesia with visceral disease.

As with the case of the ptosis, these membranes and bands are often accidentally found and have given rise to no symptoms. It has been shown to my own mind conclusively that they are present in quite young children and may even be found in the fœtus, so that they must be regarded as congenital in nature. It is, however, when such membranes and bands are found in association with ptosis that symptoms begin to appear. In the later stages there is evidence of dilatation, of atony, and sometimes indeed of inflammatory changes in the walls of the intestine, especially in those of the cæcum and colon.

Changes in General Body Structure and in Mentality.

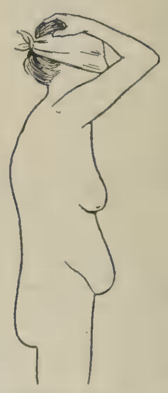
The changes in general body structure are often distinctive, and are divided into two groups known as virginal and maternal ptosis. The virginal type is very characteristic, and I have represented its most marked changes in Fig. 5. The patient is thin, sometimes wasted, she appears to be relatively tall, the tissues are soft and relaxed, and the whole body is poorly developed. These changes are sometimes evident even in quite young children, although they become more distinctive after the age of puberty. The thorax is narrow and shallow from before backwards. The lower ribs slant rapidly downwards, and there is a narrow epigastric angle. The shoulders are bent, the dorsal curve is exaggerated, and the lumbar curve absent. The upper abdomen is narrow and the waist long; the pelvis appears too wide for the body. The condition may be associated with flat-feet, "genu valgum," and sometimes with scoliosis. At times this change shows a distinct hereditary tendency. The second or maternal type (Fig. 6) is a patient who may have wide shoulders and a well-developed thorax and upper abdomen but the abdominal walls are soft and flabby owing to the patient's having had many children, and all the viscera have been allowed to drop. The lumbar curve may have disappeared and the shoulders may have become rounded.

Fig. 5.



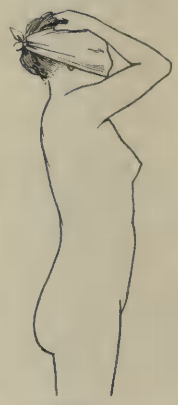
Virginal ptosis.

Fig. 6.



Maternal ptosis.

Fig. 7.



Ideal female type.

The changes in the nervous system, or rather in the mentality of these patients, are well known; owing to them a diagnosis of hysteria is frequently made. The changes consist chiefly of a lack of interest in their surroundings, of an abnormal concentration of their attention upon their symptoms, and, in fact, of a general melancholia. I have pointed out that changes in the body structure are often little in evidence, and the same is true of the mental changes. The description given above applies to an advanced case, but it cannot be too clearly realised that some of the patients with well-defined symptoms are apparently bright and healthy girls, with normal body structure, whose ptosis and intestinal changes are only recognised at operation or on X ray investigation; sometimes, indeed, these patients are good athletes, and in such the greater difficulty will arise in making a correct diagnosis.

Ætiology.

Before we consider the question of symptoms and treatment it will be necessary for me very briefly to discuss the ætiology of this condition. As you are all aware, there has been an enormous amount of theoretical discussion as to which is the primary factor. I have on many occasions discussed the evidence in favour of one or other of the views advanced, and will here simply state my own views as to the cause of the condition, and the evidence in support of these views. The mobility of the intestines, which is due to the presence of long mesenteries, is manifestly congenital, and the amount of mobility varies considerably in practically all people. If a series of normal people be investigated by the X rays the cæcum is usually lower in females than in males, but even in such normal people 50 per cent. or more may show viscera so low that symptoms would be expected to occur, and yet they have never been in evidence. The membranes and bands I also firmly believe are congenital in origin, and are not due to any reactionary change that attempts to overcome the mobility. They have been found on many occasions in quite young infants, and even in the fœtus at term. I believe that they are as common as the increased mobility, and, in fact, I have never yet seen a case with abnormally long mesenteries which has not shown some or other membrane formation. It therefore appears to me perfectly clear that a very high percentage of the human race, perhaps even indeed 50 per cent., have viscera which show a mobility and an excess in membrane formation which is usually regarded as abnormal.

Any theory to be satisfactory will have to explain why such a condition is so much more common in the female sex, for it is agreed by all observers that at least 80 per cent. of the patients are females. Although many of us may not believe in the equality of the sexes, we cannot seriously contend that woman is so much lower in the evolutionary scale that she tends to maintain the viscera of the quadruped. My own experience has shown clearly that the mobility and membrane formation is as common in males as in females; there must therefore be some other factor which makes the symptoms more common in women. This in many cases is manifestly the change in the body structure. Although a hereditary factor is sometimes found, there is as a rule in quite young children no difference between the body structure of the boys and girls. This change must therefore largely be acquired. Now it is found that these cases are much more common in women who have an unsuitable environment. It is more common in those who from an early age have to earn their own living, who have had to work for prolonged hours, often in insanitary surroundings and with little or no open-air exercise, and it is under exactly such conditions that a poor body structure would be expected to develop, leading in time to the changes in the vertebræ and thorax; it will be seen how much more likely these changes are to occur in those who show a faulty hereditary muscular tone. In the maternal type the factor is somewhat different. There is not the general loss of muscular tone, but there is the destruction of the support of the abdominal muscles and the loss of the lumbar curve.

This view will, however, still leave unexplained that group of cases where definite symptoms occur in apparently normal and well-developed women and men who have capacious upper abdomens and a well-shaped thorax. Sherrington has, however, supplied the explanation for this variety. He has shown clearly that there are two distinct groups of muscular activity, the one concerned with voluntary movements and the other with posture. Postural activity is characterised by the fact that it can be maintained for prolonged periods without fatigue. It is acquired in early life and is apparently largely the result of training. At first the various postures of the body can only be maintained by voluntary effort which is tiring and irksome, but later it becomes unconscious and can be maintained for long periods. The large number of people who were drilled in the recent war will realise how a correct stance is at first difficult to maintain, but later becomes automatic and unconscious. Now it has been recognised by many observers that many of the more athletic girls of to-day have an extremely poor carriage. They have, perhaps, developed their voluntary muscles to an extreme degree, but have entirely neglected their postural activities. Hence, although sturdy and apparently well-developed, they may have little or no tone in their abdominal or lumbar muscles, so that their viscera are allowed to drop. Moreover, loss of muscular tone is dependent upon mental fatigue, and hence is much more likely to occur in those people who have a poor mental capacity; thus it would seem that the mental changes so commonly found in these people are to a large extent primary, and that they are people who are less likely to make the mental efforts necessary to overcome their physical disabilities. In the later stages it is probable that the long continuation of their symptoms exaggerates their mental changes. It would thus seem that both increased mobility and membrane and band formation are congenital changes, which, after all, are of no importance, which exist equally in the male and female and which give rise to no symptoms; but it is the supervention of a poor muscular tone and a badly-shaped body which will allow these freely mobile viscera to drop, to become kinked, and in turn to be rendered atonic. I believe that this view is the only one which will explain the much greater frequency of this condition in women, and the fact that mobility and membrane formation is often found in patients who have little or no symptoms. It is also realised that in some of the most advanced cases of maternal ptosis no symptoms at all may be found. In such cases operation will reveal the fact that there is no membrane and band formation.

Symptoms.

It is manifest that if one viscera or one portion of the intestinal tract be more mobile or more kinked than another symptoms may be mainly directed to that portion, and thus it is that these cases come to us with a superficial resemblance to a gastric or duodenal ulcer, to gall-stones, or to appendicitis; but there are many characteristics common to all which will help to distinguish the case from one of these organic lesions. With the exception of the less common maternal type—and the relatively rare variety, starting in men about the age of 40, which may therefore resemble carcinoma of the stomach—there is, as a rule, a long history which dates back to the time the patient was at school. The patient will describe how during this long period there have been definite attacks, but careful investigation will show that she has never been perfectly free between; this fact alone will give rise to the suspicion of the underlying cause, being very different from the clear periodicity which is so evident with a gastric or duodenal ulcer. The attacks themselves are usually short, persisting as a rule only for a few days, and followed by a period of relative freedom which is often of short duration and rarely exceeds one or two weeks. Moreover, the attacks, if progressive in their severity, are only so to a very slight degree, and thus differ considerably from the attacks found with a chronic appendicitis. It is a difficult thing to visualise any pathological process within the appendix which could recur some 15 or 16 times and yet never would have led to an abscess or severe inflammatory change.

The pain is often described as "severe," but since our judgment of its severity is based on the patient's statement it is difficult to determine its degree; it is, however, manifestly not so disabling as the severe pain of an ulcer or of a gall-stone colic. It is frequently wide and diffused over the abdomen, although its point of greatest severity may be in the epigastrium in the gastric cases, or in the right iliac fossa in the pseudo-appendix cases. In the former it will not have the same definite relationship to food as with a gastric ulcer, or if made worse by food the increase will be noted almost as soon as the food is ingested. Another characteristic fact is that it is usually better in the morning and increases as the day goes on, generally to be relieved again when the patient lies down in bed. This dependance upon the patient's position, although not absolutely constant, is usually a marked feature, and one of my patients—an intelligent woman—had learned to stand on her head during her severe attacks and gained almost immediate relief thereby. In a similar way it is frequently noted that after a tiring or exhausting day the symptoms are more manifest. In the right iliac fossa, again, it is often noted that there is an exacerbation with each menstrual period, probably owing to the increased congestion of the pelvic viscera, and it is probably for this reason that so many of these patients have been operated upon for ovarian trouble.

The vomiting is generally a marked feature, much more so than in the case of an organic lesion. It is often present several times in the day, and in the younger women especially may continue for two or three weeks at a time. It is such conditions which are often diagnosed as chronic gastric ulcer; but it must be remembered that gastric ulcer cases usually only vomit in occasional attacks, and even if they do so the vomiting is rarely severe. The nature of this symptom is also sometimes helpful in the diagnosis of acute appendicitis, for in this condition a patient, as a rule, only vomits once at the onset of an attack. The act of vomiting often gives little or no relief, such as it does with gastric lesions other than carcinoma.

Hæmatemesis is a frequent symptom in the gastric type, especially in the younger women. In my own experience some 50 per cent. of the cases have had a sharp loss of blood at some time or other in the course of their disease. The loss of blood is manifestly due to the supervention of small gastric erosions in a dropped stomach. The appetite nearly always shows a characteristic change. There is a very definite loss during the attack, and this may indeed be as marked as the change which is seen in cases of carcinoma. Generally, however, there will have been the long history of many years attacks with severe loss of appetite in each. Even between the acute attacks the appetite is capricious; the patient will often state that she has little or no desire to eat, and that she has to be careful in the choice of diet lest severe symptoms be induced. Constipation is a frequent concomitant, and in fact many observers regard this as the primary cause. The majority of such patients will state that they rarely have a movement of the bowels without some aperient, but some will state that they are better when the bowels are freely moved, others that they are not so well. It must be remembered here that in the long-standing cases, where the stasis is advanced, there may be diarrhœa instead of constipation, owing to the onset of colitis from the previous stagnation.

In addition to these general symptoms the patients will often state that they have a feeling of general malaise, of lack of interest in their occupation, and of general inertia. In fact, it is a very frequent thing to find young women presenting no physical signs of any gross disease who have been unable to carry out any employment, or indeed to lead a life other than that of a semi-invalid, for many years.

On physical examination the types vary enormously. An extreme case will show the typical changes of mental depression, the characteristic features of the "ptosis habitus," and evidences of dilated and dropped viscera. Such conditions can hardly be overlooked if their possibility is remembered, but it is in the more intelligent type of patient who has a better physical development that difficulties in diagnosis are more manifest. In them a careful outlook will have to be maintained for the presence of positive physical signs. It is well to remember that unless there are complications a patient with gastric or duodenal ulcer or gallstones will show little or nothing beyond a localised area of deep tenderness. A patient with ptosis, although perhaps having a well-shaped abdomen, will generally manifest evidence of loss of tone, so that in the erect posture there will be a sinking-in of the upper abdomen and a protrusion of the lower portion. Not infrequently definite areas of hyperæsthesia give a clue to the correct diagnosis, and Fig. 4 shows the areas of hyperæsthesia associated with gastric dilatation or acute ulceration, and of dilatation of the cæcum, which are to be contrasted with those of a dilated and diseased gall-bladder or appendix. A chronic gastric or duodenal ulcer is never associated with areas of hyperæsthesia. On abdominal palpation the deep tenderness in a case of ptosis is more widely diffused, corresponding either to the whole area of the stomach or cæcum or being manifest over the whole lower abdomen. The dilated stomach and cæcum are frequently palpable, for distinct splashing may be obtained over either viscus on palpation. Attention should always be directed to the right kidney, which is often abnormally mobile. The examination of the test-meal is often of little value, for although in the majority of cases both free hydrochloric acid and total acid are much diminished, in some cases they are well above normal and may indeed be as high as those found in a duodenal ulcer. X ray examination, if conducted by one well skilled in this branch of work, is often of value. There will be the absence of the positive signs of a gastric or duodenal ulcer, the stomach, the colon, and the cæcum will frequently be abnormally low, and, what is perhaps of more importance, they will show a definite delay in emptying. It must be remembered that this delay is often associated with abnormally active movements, so that irregular areas of spasm and contraction are seen, but they do not empty the viscus. General constitutional changes, to which Sir Arbuthnot Lane has directed so much attention, such as a sallow complexion, foul breath, chronic mastitis, and areas of pigmentation, are usually only seen in late and advanced cases when the diagnosis presents little if any difficulty.

TREATMENT.

It is well to remember that the primary treatment of this condition is essentially medical. The congenital factors of abnormally long mesenteries and membrane formation, although an important part of the disease, will give rise to no symptoms unless the loss of muscular tone be superadded. Such loss of tone with its consequent alteration in the body structure cannot be overcome by operative treatment. Often, indeed, it is so advanced that even a complete alteration in the patient's manner of life and the most careful medical treatment will fail to overcome the established deformities. The essential fault to remedy, however, is the carrying out of surgical treatment in the belief that a definite organic lesion is present. The details of medical treatment which should be carried out in these cases I shall not enter into here, but they will always be prolonged and tedious, and will include careful attention to physical exercises combined with rest, general hygiene, dieting, and medical treatment. Since the patient's condition of life is such that she often can give neither the time nor the money for such a course of treatment, it is manifest how difficult is the cure. Only after such a course of medical treatment should any question of operative interference be considered. A large number of operative measures have been put forward from time to time as a cure for this distressing complaint, but the value of every one has in the past been grossly exaggerated; one has only to remember how widespread are the changes to realise that any form of operation will fail to overcome them all, and it must therefore be clearly understood by the physician or surgeon—and should, indeed, be explained to the patient—that any form of operation can at best give partial relief, and will have later to be combined with medical treatment. In other words, if the medical treatment alone has failed, an operation may be added in order to make that medical treatment more successful.

The next factor on which personally I lay great stress when deciding to operate is the localisation of symptoms. If these are diffuse, if there is much mental change and a poor body structure, it is evident that any operative treatment that hopes to be successful would have to include a widening of the lower thorax, a restoration of the lumbar curve, a fixation of all the affected viscera, and a return of the muscle tone. Such an operation is, of course, impossible, and the best results, therefore, are likely to accrue when one viscus is not alone at fault but is the only one sufficiently abnormal to give rise to symptoms. Thus, if the patient complains almost wholly of gastric symptoms, attention can be directed to this viscus with every hope of amelioration, and the same is true with right-sided symptoms limited to the cæcum and ascending colon, but it must be clearly realised that claims which have been made that the mobility of one viscus is the cause of the widespread symptoms are incorrect. No primary mobility of the cæcum could possibly give rise to the secondary mental changes and dropping of the transverse colon and stomach, or to the increased length of the pelvic mesentery. It is also manifestly incorrect that a mobile cæcum is the cause of chronic gastric and duodenal ulcer, for all observers are agreed that although ptosis is a very common condition, and is often mistaken for these lesions, it is but rarely found associated with them. Ptosis is a disease of relatively young women, gastric and duodenal ulcers are much more common in adult men.

The actual steps in treatment will be two-fold. Any obstruction of the viscus from kinking by bands or membranes will have to be overcome. This may be accomplished by division of the bands, or in some cases, as in chronic duodenal ileus, an anastomosis will be necessary. Remember, however, that a gastro-enterostomy for a dropped stomach is almost certain to be unsatisfactory, probably because the tone of the gastric muscle is much below normal. When all the kinks and obstructions are overcome it will be necessary to fix the dropped viscus. The technical methods of performing such a step I shall not enter into to-day, but the fixation should be such that it interferes as little as possible with the motility of the viscus and causes little or no deformity. The viscera to which such fixation has been most successful are the right kidney, the cæcum and ascending colon, the stomach, and the transverse colon, but my own experience has been that a measure of relief is only afforded if the symptoms are almost wholly limited to one or other of these viscera, and even when such an operation has been performed medical treatment must be carefully continued, and the conditions of life of these patients, which preclude the possibility of adequate exercises, will often necessitate the use of some abdominal binder or support.

Resection of some portion of the intestinal tract, whether of the cæcum alone or of the whole colon, is tending to have a more and more limited field ; like many other surgeons, I find that I am performing this operation very infrequently. In my opinion, it should be limited to extreme cases in which the colon is not only low, but also very atonic. It is an operation which is associated with a considerable mortality, and therefore it will not often be justified as a form of treatment foı a condition which, although very disabling, does not in itself lead to the death of the patient.

THE THYROID APPARATUS IN MAN.[*]

By G. SCOTT WILLIAMSON, *M.C.*, M.B.,
Ch.B. Edin.

(From the Department of Pathology, Royal Free Hospital, London.)

The first application of the recently published work on the structure and physiology of the thyroid gland is to review the integration of the various organs associated with the thyroid gland function. Launoy[1] has very completely reviewed the facts in favour of considering the thymus, thyroid, and parathyroid, not merely as associated structures, but as one functional apparatus. Critical examination of material from 2000 post-mortems affords considerable substantiation of the point and perhaps affords a guide to the specific function of the apparatus.

Anatomical Features of the Thyroid Apparatus.

The Thyroid Organ.—The thyroid organ consists of two compact lateral lobes. The upper pole of each lobe is marked off by a constriction below which lies the bulk of the lobe. Immediately below this constriction a band of thyroid tissue projects across the middle line from each lobe to form an isthmus, or from each side it extends up the neck along the line of the thyro-glossal duct to form a pyramidal lobe or lobes. The lobes of the gland have no capsule proper ; they lie in a special compartment of the fascia of the neck. This fascial compartment is usually shut off from the mediastinum on each side by a fibrous tissue diaphragm. Each lobe has a hilus, where the loose fascia dips into the gland substance to become the interstitial tissue of the organ. The hilus lies posteriorly on the mesial surface of each lobe under cover of the base of the isthmus or pyramidal lobe. The large inferior thyroid artery enters the lobe at the lower end of the hilus, and the smaller superior thyroid artery at the upper end, these arteries are usually united by a communicating vessel that occupies the length of the hilus. Only small venæ comites emerge from the lobe at the hilus. The veins and lymphatics emerge at the surface of the lobes and unite in the loose fascia to form a plexus of veins and lymphatics which is continuous in the fascial compartment with a similar plexus from the thymus. The vascular supply within the lobes is characterised by a considerable capillary anastomosis between arteries and veins in the interstitial tissue of the lobe, providing, as it were, a short circuit, before the very specialised capillaries of the functional unit are given off. (Kidney and liver present a similar arrangement.) Certain anomalies in the gross anatomy must be noted. Accessory lobes are a frequent occurrence, most commonly at the lower pole of the lobe. An accessory lobe may lie in the mediastinum beyond the fibrous diaphragm. The upper pole may constitute one of these accessory lobes. The compact gland may give place to a multilobar gland, the small independent lobes being scattered in the fascial plane from the hyoid bone to the root of the great vessels in the mediastinum, there being no fibrous tissue diaphragm separating the thyroid and thymus tissue. The isthmic tissue may be absent on one or both sides. The arteries are the subject of great variation. The superior artery may be the larger or the only vessel, or may be absent. Very frequently both arteries break up on entering the fascial compartment into numerous branches, which enter the hilus independently, so that neither superior nor inferior thyroid can be recognised in the hilus. (Fig. 1.)

Microscopic Anatomy of Thyroid.[2]—The lobes of the thyroid organ are divided up by interstitial tissue septæ into lobules. The lobules consist of a collection of gland units having a specific structure. Each gland unit is enclosed in a fibro-elastic tissue capsule, giving support to the endothelium of a lymphatic sinusoid, which is an expansion of the intralobular lymphatics. Within the sinusoid lie coiled columns of epithelium. The columns of epithelium are surrounded by a peculiar ladder-like plexus of capillaries, their walls of endothelium are unsupported by any fibrous tissue. These capillaries emerge at two or three points, penetrate the endothelium of the sinusoid, and become the intralobular vessels—artery and vein being indistinguishable within the limit of the lobule.

Thyroid Epithelium.—The appearances presented by this epithelium will vary with the phase of physiological activity. The architecture of the epithelium is seen only in the indifferent phase. In this phase the epithelium, seen in section, corresponds to the "interfollicular tissue" of the literature, about which controversy has raged. The existence of a system of micro-capillaries in the substance of the epithelial column[2] serves to distinguish it from parathyroid tissue and to identify it with the general body of the gland in the other phases of activity. In this phase the column of epithelium seems solid. The central zone of the column is demarcated by the system of micro-capillaries. The central core of the zone contains a homogeneous protoplasm continuous through the mesh of the micro-capillary system with the protoplasm of the periphery. The nuclei lie in a central position near the closed mesh of the micro-capillary system. The epithelium has all the appearance of a syncytium, and contains no colloid, no secretion, and there is no granular matter in its protoplasm. The opaque areas to which particular attention has been called[3] may be made up of epithelium in this phase.

Parathyroid Bodies.—The parathyroid bodies, two in number, lie at the upper and lower ends of the hilus in each lobe, in close association with the superior and inferior thyroid arteries. They are bean-shaped bodies, having a soft, almost diffluent consistency. In the cadaver they are pigmented bodies often indistinguishable from the pigmented fat in which they lie. In life, neither the pigment nor the fat with which they are associated is obvious. They are not to be confused with the special lymphatic glands that also constantly occupy the region of the hilus. Each parathyroid body draws its arterial supply from the associated thyroid artery. The venous return drains into a specially large vein, which joins the plexus on the surface of the thyroid gland. A considerable branch from the sympathetic is lost in the substance of each parathyroid body. Anomalies in the structure and distribution of the parathyroid bodies are common; there is, however, a definite relation between them and certain anomalies already noted in the thyroid. They each vary in size with similar variations in the size of their associated superior and inferior arteries. When there is only one artery entering the hilus of the lobe, there is only one parathyroid body, proportionately larger in size. When the arteries break up and enter the thyroid gland as independent twigs, there is no macroscopic evidence of a formed parathyroid body; microscopically, the tissue is spread out over the extent of the hilus. In the multilobar state of the thyroid no parathyroid tissue is to be found. When there is a single large parathyroid, the branch from the sympathetic trunk is a very obvious macroscopic structure, and is seen to end in the substance of the large body.

---

[*] Assisted by a grant from the Medical Research Council.

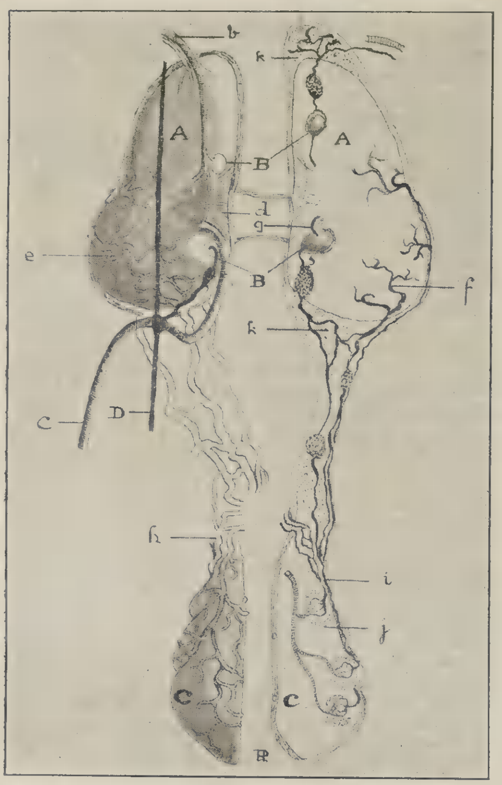


Fig. 1.—Schematic drawing of the thyroid apparatus.

A, thyroid gland: (a) hilus, (b) superior thyroid artery with parathyroid branch, (c) inferior thyroid with branch to parathyroid body, (d) intercommunicating artery, (e) capsular veins, (f) capsular lymphatic plexus.
B, parathyroid bodies: (g) ancillary lymphatic.
C, thymus: (h) venous plexus, (i) afferent lymph channels, (j) thymic lymph nodes, (k) superior and inferior (thymic) lymph-fat-gland bodies.
D, sympathetic trunk with parathyroid branch.

Microscopic Anatomy of Parathyroid Bodies.—The parathyroid bodies are composed of a series of systems of tubes. The tubes usually appear as columns of cells generally cubical in shape. The first part of their course is more or less radial. Centrally, they are coiled and convoluted, and when empty their appearance suggests a sponge work. Fibrous tissue accompanies the radial portion of the tubes, but only the capillaries penetrate to the central spongy zone. The lining cells of the tubes are subtended by a reticulum of large granular polygonal cells. Nerve fibres run in this reticulum. Granules of refractile, yellow-brown pigment occupy the clear cytoplasm of the cells lining the tube; this is more abundant, as a rule, in the radial portion of the tube. Certain anomalies are of interest. The body may be divided up by fibrous tissue septæ, so that there is no discernible spongy centre, each member of the series of systems of tubes being more or less a separate entity. Frequently the systems that compose the body occur scattered independently through the fatty tissue in the hilus of the gland, the compact nature of the body being lost; this occurs when the thyroid arteries enter the hilus as a congerie of branches. The degree of scattering that occurs in the multilobar thyroid may explain the inability to find parathyroid tissue.

The Thymus.—The thymus lies in a special fascial compartment in the mediastinum, separated from the thyroid compartment by a fibrous diaphragm. It is composed of two leaves of tissue, each with a central branched stalk of fibrous tissue. In the fibrous tissue stalk and its branches run numerous arteries which end as glomerular tufts. About the glomerular tufts lie the reticulum cells of the thymus tissue. The blood leaves the gland at its surface by numerous veins which join the venous plexus of the thyroid gland. Large lymphatics run with the veins and form a plexus continuous with that of the thyroid gland. There are numerous lymphatic glands at the root of the neck within the thyroid-thymus fascial compartment associated with this plexus. In a generalised pigmentation of the deep and superficial cervical, the mediastinal and bronchial lymph glands, this system of lymphatic vessels and glands escapes pigmentation; it is, in fact, peculiar to the thyroid and thymus. The characteristic Hassall corpuscles lie in the fibrous tissue stalk or in its branches; they seem unconnected with the thymic reticulum, and are the only vestigial tissue in the thymus. Thymic tissue proper does not atrophy, but undergoes a very characteristic metatrophy. The lymph glands and fat in the hilus of the thyroid lobe present certain peculiarities. The lymph gland has no capsule, so that its reticulum is apparently continuous with that of the reticular mesh containing the fat. The colour of the fat varies with the colour of the thymic fat. As a rare occurrence this lymph-fat-gland tissue contains concentric bodies having the characters of Hassall corpuscles. This applies also to other lymph-fat-gland tissue encountered at the upper and lower pole of the thyroid lobe, each of them being constant structures. These appear to be part of the special lymphatic system more or less peculiar to the thyroid apparatus. This is often very strikingly brought out, in cases where the whole of the lymph glands of the neck, deep and superficial, are deeply stained with carbon-pigment. The glands of the thyroid apparatus remain as definite flesh-coloured structures devoid of pigment. This also applies to the thymic lymph-fat-gland tissue. The writer is of the opinion that these lymph-fat-gland bodies are essentially thymus tissue.

Anomalies.—The fibrous tissue diaphragm is commonly drawn up as a funicular extension attached to the lower pole of the thyroid lobe; in this lie the lymphatic plexus and lymph glands. The fascial compartment of the thymus is very frequently common to thymus and thyroid. Thymus tissue may be encountered anywhere within the compass of distribution of thyroid tissue in its anomalies. That applies not only to the endothelioid element but to the Hassall corpuscle element. In the multilobar form of thyroid the thymus and thyroid are inextricably mixed up. We have encountered an entire absence of medastinal thymus with hypertrophy of the neck nodes. The branches of the fibrous stalk may penetrate to the surface of the gland and isolate each glomerulo-reticular zone, resulting in the thymus appearing as a collection of discrete units not unlike a bunch of grapes. (Fig. 2.)

Physiological Features of the Thyroid Apparatus.

The architecture of the thyroid apparatus, as set out above, is modified in quite definite directions by the furniture of physiological occupation. In the thyroid gland two cycles of operation present themselves: (1) a secretory phase; (2) a vesicular colloid phase. Neither can change over to the other without passing through the indifferent phase already noted.

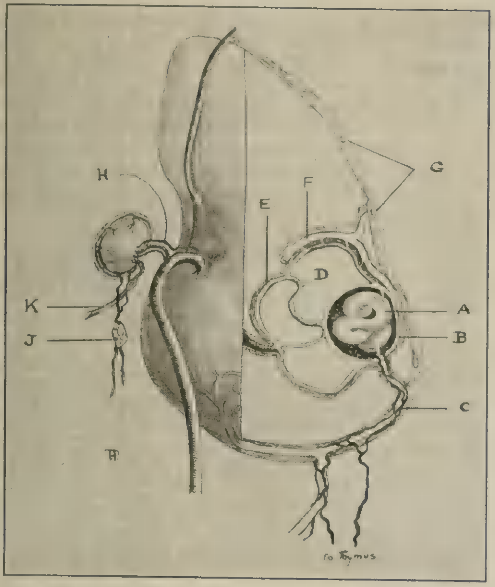

FIG. 2.—Schematic drawing of thyroid mechanism showing its connexions.

A, epithelial unit lying in B, the lymph sinusoid, draining into C, capsular lymphatics; D, arterio-venous vascular supply arising from E, interlobular artery which communicates with F, the interlobular vein, which empties into G, the capsular plexus; H, ancillary lymph channels emerging from the hilus to enter I, the parathyroid body from which they emerge and enter J, lymph-fat-gland tissue (? thymus); K, branch from sympathetic.

The Secretory Phase in the Thyroid Gland.—This is an active process in which the epithelium, the sinusoid, and all the endothelium of the gland units participate. In all its stages it gives the opaque appearance on macroscopic inspection that is also a feature of the indifferent phase. The details of this process of secretion are set forth in the original communication, from which the following summary is taken. The sequence of events is: (1) the opening up of the potential space of the lymphatic sinusoid by fluid matter; (2) a change in the endothelial cells lining the sinusoid associated with which lymphocytes appear in the intralobular lymph channels, and frequently also in the sinusoidal space; (3) swelling of the epithelium, migration of the nuclei to the extreme periphery, and the appearance of two orders of granules; (4) vacuolation of the protoplasm and partial solution of the granular matter in the fluid of the vacuoles; (5) lacunation of the epithelium by the accumulation of the contents of the vacuoles in the central core of the column of epithelium; (6) the tubules in the protoplasm of the epithelium appear to swell and conduct granular fluid; the radial branches become quite turgid.

Changes in the parathyroid bodies are definitely related to the nature and quantity of the secretory phase in the thyroid gland. The commonest condition is associated with the presence of fluid matter in the sinusoids of the thyroid gland during the course of secretory activity. The fluid matter (not colloid) can be traced directly to the tubes of the parathyroid bodies, giving to these structures a pseudo-vesicular appearance which has led to the confusing of thyroid and parathyroid tissue. One other feature of active secretion, more particularly associated with its lacunar phase, is the aggregation of lymphocytes in the sinusoids and lymphatic channels. These also overflow into the parathyroid bodies—so much so that they can completely obscure the architecture of the bodies. The lymphocytes are found, not only in the lumen of the tubes, but also in the inter-tubal tissue among the polygonal cells. These changes are proportionate to the amount of activity in the thyroid gland. The secretory activity of the thyroid gland is as intimately associated with changes in the thymus. Any increase in the secretory activity is invariably associated with an increase in the quantity of the lymphocytic element in the thymus; any decrease is associated with fat accumulation at the expense of lymphocytes. In favourable cases the fluid which we have seen in the sinusoid during activity in the thyroid gland can be traced, almost in continuity, to the lymph channels in the surface of the organ, and from thence through the plexus to the thymus. Little pools of this fluid are often found in the thymus tissue. Active changes in the endothelial element of the thymus are associated with the accumulation of lymphocytes in the tissue. It is possible to gauge the stage of secretory activity in the thyroid by studying the relation of lymphocytic accumulation in the thymus and in normal individuals the reverse is also true (this last does not hold in certain pathological states). As the lymphocytic change appears, the stored fat disappears, and there is evidence that the fat is actually used in the making of the lymphocytes—the change in the thymus from a fat to a lymphoid organ is, in fact, a metatrophy and not an atrophy, and it is the prevalence of secretory activity in the thyroid gland which determines this in health. The secretory phase in the thyroid gland is a most variable quantity. In fœtal life it is present to some degree in the midst of the indifferent tissue. In infancy it definitely increases in amount and continues to do so to about 9 years of age, and from that age remains stationary in quantity up to puberty; after puberty it increases, but not in any degree of disproportion, since the whole gland hypertrophies in a balanced manner—secretory, vesicular, and indifferent tissue in mutual relationship; after 18 to 20 years it diminishes in amount and colloid increases in amount. It cannot be sufficiently emphasised, however, that this age variation in the quantity of secretory activity is large, and difficult to estimate because each individual seems to be a law unto himself as regards the degree to which he depends on secretory activity of the gland. Further, it is very probable that each individual has seasonal as well as decadal variations. Nevertheless, the above facts stand out in an analysis of 2000 cases with considerable emphasis.

Response of Thyroid Apparatus to Age Variations.

The whole apparatus responds to these variations; thus the thymus would begin as a mixture of fat and lymphoid in the fœtus, and gradually acquire more lymphoid element at the expense of the fat up to 9 to 10 years, thereafter remaining stationary to puberty. With the hypertrophy of the thyroid and the consequent increase of secretory activity the lymphoid element would increase and the fat disappear, but without any actual increase in the bulk of the organ. When, on the other hand, the individual shows little increase in secretory activity and much colloid storage, the fat tends to disappear as well as the lymphoid tissue. At 18 to 20, when the thyroid is set as a nearly pure colloid storage, again fat perceptibly increases in the thymus, and this increase again is more related to the extent of the decrease in secretory activity than to the actual colloid storage.

In general disease, I am of opinion that the variations seen are no greater than those encountered in health. Rupert Farrant's[4] study of the thyroid gland in acute specific fevers becomes therefore a description of the very protean nature of the gland encountered in children of the fever age. Certain specific diseases still further emphasise this relationship of thyroid and thymus. Secretory activity is linked up to the lymphoid states, such as acute lymphatic leukæmia (in children), myasthenia gravis, certain intestinal lymphoid hypertrophies extraordinarily common in infants and children, either generalised in lymph-nodes or focal, as at the appendix and pyloric antrum, and in persistent thymus and status lymphaticus. In all these states a pathological degree of secretory activity is evident in the thyroid gland.

In other conditions in which the thyroid gland shows secretory activity—as in eclampsia, status epilepticus, rickets, and the adenoid state in children—the lymphatic tissue, including the tonsils and lymphatic glands, shows a loss, often complete, of any lymphocytic activity. The thymus in these states is a simple endothelioid organ without fat and without lymphocytes—exhaustion best describes the condition. In a few cases of diabetes this condition of affairs also prevails. It is only necessary to recall the fact that a considerable school of observers look upon exophthalmic goitre as a thymic disease to emphasise the inter-relation of these two organs in that heterotrophic state in the thyroid gland.

Vesicular Colloid Phase in the Thyroid Gland.—The summary of this phase is taken from the original paper, and is as follows: (1) Vesiculation occurs in definite areas of the epithelial columns of the gland-unit; (2) vesiculation leads to the fragmentation of the columns into discrete spheroidal vesicles; (3) vesiculation is not accompanied by any demonstrable biochemical disturbance of the nuclei or protoplasm of the epithelium; (4) the gland-unit passively suffers distension and distortion to the extent of losing its identity under the process.

In the normal individual stored colloid varies inversely with the secretory activity in the gland up to a point. This is not invariably so, for in marasmus colloid disappears without any increase in secretory activity—i.e., there is a reversal towards the fœtal state in the gland. Thymic fat does not necessarily disappear in these conditions, but there is no increase in the lymphoid element. Even in children and young adults, vesicular goitre is associated with a fat-laden thymus, and this may have some specific significance. For the rest, stored colloid is almost a measure of thyroid inactivity, but so long as metabolism has a maintenance value secretory activity does not follow colloid depletion.

Conclusions.

The thyroid gland, the parathyroid bodies, and the thymus are intimately related anatomically, physiologically, and pathologically. They constitute an apparatus probably engaged in the conduct of some specific function. The thyroid gland is the main organ. The parathyroid is a sentinel gland of neuro-lymphatic nature, set in the course of the effluent, probably engaged in measuring the efficiency of the thyroid gland, and through the sympathetic nervous system adjusting its operation to the needs of the body. In the experience of the writer, certain pathological conditions of the kidney—or renal apparatus—indicate a similar relationship between the kidney and suprarenal body—the term neurotrodal gland would indicate the significance of such structures on the analogy of the electrode.

The thymus is a reservoir for the effluent—which, according to its nature is stored either as fat or in the lymphocytes. This must not be taken to imply a movement of lymphocytes into the blood or lymph; the probability is that they are manufactured in situ, and absorbed in situ. (See also Cramer's work on the possible significance of the blood platelets.[5])

The fact that colloid usually disappears to give place to any secretory activity, and the fact that it need not be so associated as in marasmus and in early fœtal active glands, make it probable that the colloid is exercising some vehicular function analogous to some of the constituents of bile. It is only passively concerned in the operation of the thyroid apparatus.

The most important feature of these conclusions is the implication of the lymphocytes in the operation of the thyroid apparatus. It presents the most promising line of investigating the function of this apparatus. Indeed, I approached the whole problem from a study of the inter-relation of purin-creatin and amino-acid nitrogen in intestinal disease of children, and was led from that to the heterotrophic lymphoid conditions, local and general, and through them to the thyroid gland.

Certain preliminary chemical studies—more particularly directed to the problem of the ætiology of gastric ulcer[6] and appendicitis—fix upon nitrogen carriage as the significant function of the lymphocyte, and this from the point of view not so much of total nitrogen as of the nature of the nitrogen (nucleo-protein, purin, amino-acid, peptide), so that the writer is working on the hypothesis that the thyroid apparatus is primarily concerned in controlling the direction of protein synthesis within the body—making it either a synthesis of plastic nitrogen, or trophic nitrogen, as the case may demand, the thymus being the reserve store of such nitrogen. Even the fat phase in the thymus yields nitrogen values for the tissue that are significant. Jackson[7] has already published observations which implicate secretory activity in the thyroid with protein metabolism, and Noel Paton's work,[8] looked at from a point of view not so exclusively endocrine, would have the same significance if lymphocytes, being the nitrogen carriers, varied their nitrogen partition from purin to non-purin according to need. Cramer's[9] work, and that of Cramer, Drew, and Mottram[10] on the lymphocyte, may have a similar significance.

Experimental work in this direction will further demand that some note be taken of the excretion of nitrogen other than the end-products of completed katabolism. This probably takes place through the gonads, making them, as it were, the kidneys of the plastic phase of metabolism, through which are excreted the end-products of completed anabolism. Protein metabolism (perhaps all metabolism) being a completely reversible chemical reaction, katabolism at the one end and anabolism at the other end, each implying complete catathesis of the substrate, the excreted end-products differing with the *direction* of the reaction.

A consideration of the significance of the conclusions in experimental ablation of the various parts of the thyroid apparatus is necessary. Clearly the effect of ablation may depend largely upon the relation of the individual to the secretory activity of the thyroid. This is the most variable feature of the gland. Thus it becomes necessary to postulate that in any experiments of that nature it will be necessary to reduce the individual to a definite dependency on secretory activity in the thyroid gland. Jackson and Mellanby's[11] work points to a means of achieving this, so that it may become possible to reconcile the contradictions which are the only striking results to date from experiments of this nature. The same criticism applies to the various thyroid extracts. Any extract of an average normal gland will largely consist of colloid extractives plus any constant peculiar to thyroid tissue, and the most variable quantity of traces of an active secretion. Here, also, it will be necessary to consider the thyroid gland as a resting organ in the indifferent phase, as a colloid storage organ, and as a secretory gland, and each of these in the lymphoid, fat, and exhausted stage of the thymic store, before we can hope to solve the problem of any autocoid activity the apparatus may possess.

ON IMMUNO-TRANSFUSION.

By LEONARD COLEBROOK, M.B., B.S. Lond.,
ASSISTANT, BACTERIOLOGICAL DEPARTMENT, MEDICAL RESEARCH COUNCIL;
AND
E. J. STORER, M.R.C.S.,
ASSISTANT, INOCULATION DEPARTMENT, ST. MARY'S HOSPITAL, LONDON.
(From the Inoculation Department, St. Mary's Hospital.)

In the course of a lecture on the treatment of infected war wounds[1] in 1919, Sir Almroth Wright advocated the transfusion, in certain cases, of immunised blood. This procedure, to which he applied the term "Immuno-transfusion" affords a last resource, he said, for patients suffering from septicæmia, when all that the surgeon can do has been done and when no response can be obtained to the inoculation of vaccines. He did not advocate simple transfusion because he had found that the normal blood-fluids contained, as a rule, less protective substances than those of the infected patient. As a matter of fact, simple transfusion had already been tried and had proved unavailing. The immunised blood, which Sir Almroth Wright proposed to employ, was blood taken from a healthy donor and subsequently inoculated in vitro with such a quantum of vaccine as would suffice to render its plasma bactericidal for the microbe with which the patient was infected. As an example of what can be achieved by such a procedure Sir Almroth Wright gave a brief account of a desperate case of wound infection which had been successfully treated on these lines.

During the four years which have elapsed since this lecture was given certain new facts have come to light which serve to reinforce the suggestion that this method of treatment will prove to be of great value. We have learned—by simple experiments which were fully set out in a recent paper by Wright, Colebrook, and Storer[2]—why it is that immunising responses cannot be obtained in the very heavy bacterial infections which Sir Almroth Wright had in mind. The experiments show that the patient's leucocytes are chiefly at fault. Although in respect of numbers, they are not usually deficient, yet in respect of bactericidal functions they are often far below the normal level. They fail to furnish protective substances—i.e., to make an immunising response—when brought in contact with microbes outside the body, and their phagocytic power, and their power of killing microbes extracellularly are also reduced. It is not surprising that patients whose blood shows such defects should, if left to themselves, go from bad to worse. The infecting bacteria multiply and produce toxic substances, while the leucocytes, poisoned by these toxic substances, are unable to destroy the bacteria. Further, in such circumstances, it will be clearly useless to inoculate the patient with vaccine—he is unable to respond to it and will only be harmed. We may, however, sometimes be able to turn the scale in his favour if we can confer upon him a temporary passive immunity, as Sir Almroth Wright proposed, by means of the bactericidal plasma we inject, and if, in addition, we furnish him with a large body of normal leucocytes, capable of making an active immunising response. This is what we seek to do by immuno-transfusion.

Procedure for Carrying Out an Immuno-transfusion.

Our chief aim in this paper is to set out what has been learned from the treatment of a number of patients by this method. The problems of procedure may conveniently be dealt with under the following headings:—

1. Tests which enable us to determine whether an individual patient ought to be treated by the inoculation of vaccine or by immuno-transfusion.
2. Choice of a donor.
3. Immunisation of the donor's blood.
4. Considerations which make us elect to use defibrinated blood rather than unaltered blood or blood in which clotting has been prevented by the addition of decalcifying agents.
5. Procedure for drawing off the blood from the donor and defibrinating it.
6. Study of the question whether, when circumstances require it, the donor's blood may be kept for a few hours before it is injected into the patient.
7. Procedure for injecting the blood into the patient.

Tests to Determine whether a Patient should be Treated by Inoculation of Vaccine or by Immuno-transfusion.

In view of what has already been said it will be clear that what we most want to know about every patient who is suffering from a heavy bacterial infection and is not doing well, is whether his leucocytes are capable of making immunising responses. The direct way to ascertain this is by carrying out a vaccine-response test. For this purpose we take about 1 c.cm. of the patient's blood, defibrinate it, and then, keeping one portion as a control, add to several other portions progressive amounts of any bacterial vaccine which we know to be a satisfactory antigen. After incubation of the bloods for half an hour or so at 37° C., we centrifuge them and test the opsonic powers of the several sera, using for this purpose a staphylococcal or any other suitable bacterial emulsion.

If, on counting the phagocytic intake, we find that the serum derived from one or more of the vaccinated bloods has a notably higher opsonic power than that of the control serum, we conclude that the leucocytes have made an immunising response to the quantum of dead microbes added to those bloods, and we infer from the in vitro experiment that they will also in vivo respond to that quantum of dead microbes (vaccine) when injected directly into the blood-stream. Immuno-transfusion, for the time being, at any rate, is not required for this patient. If, on the other hand, our test shows that vaccination of the blood has not resulted in any increase of opsonic power we infer that the patient's leucocytes are so poisoned as to be incapable of making responses and that immuno-transfusion is indicated.

It will be said, however, and rightly, that the carrying out of a vaccine-response test of this kind takes more time than can usually be devoted to an individual patient. Happily we can substitute for it simpler tests which can be carried out in a few minutes by anyone familiar with "opsonic" technique. Simplest of all will be the evaluation of the phagocytic (not the opsonic) power of the patient's blood. For that purpose all we require to do is to obtain small samples of blood from the patient and a normal individual—two or three drops from the finger will suffice—defibrinate each of them, and then put up phagocytic mixtures consisting of:—

(*a*) 2 vols. of the patient's blood + 1 vol. of a staphylococcal or other suitable bacterial suspension.
(*b*) 2 vols. of the normal blood + 1 vol. of the same suspension.

After incubation of these mixtures for 15 to 20 minutes the phagocytic intake occurring in each is counted in the usual manner. The amount of phagocytosis found in the two specimens will depend, of course, upon the operation of two factors in each sample of blood—viz., the opsonic power of the serum and the activity of the leucocytes. Experience has shown, however, that where a very low phagocytic count is obtained with the patient's blood—say one-third or less of that obtained with the normal blood—this will very seldom be due to a serious deficiency of the opsonic power of the serum: almost always it will be due to a diminished activity of the leucocytes. Further, experience has shown that if the blood of such a patient be submitted to a vaccine-response test we shall obtain only a negative result. We may take it, then, as a rough working rule that where the phagocytic intake obtained with the patient's blood is one third or less of that obtained with the normal blood, the patient's leucocytes will be incapable of making satisfactory immunising responses to injection of a vaccine, and that immuno-transfusion is indicated.

Where the laboratory worker has rather more time at his command than is required for the very simple test just described he may with advantage evaluate separately the opsonic power of the patient's serum and his leuco-phagocytic efficiency. This constitutes the "chiastic test" (Wright[2]). Small samples of defibrinated blood are obtained as before from the patient and a normal individual (preferably one whose blood is of the same group as that of the patient, in order to avoid agglutination of the red corpuscles in the phagocytic mixtures). The two samples are centrifuged and the serum removed from each; the corpuscles are next washed in two changes of physiological salt solution, and a suitably diluted bacterial suspension prepared. The following phagocytic mixtures are then put up in opsonic pipettes:—

(*a*) 1 vol. of washed corpuscles prepared from the patient's blood + 1 vol. of normal serum + 1 vol. of the bacterial suspension.

(*b*) 1 vol. of washed corpuscles prepared from normal blood + 1 vol. of normal serum + 1 vol. of the bacterial suspension.

(*c*) 1 vol. of washed corpuscles prepared from normal blood + 1 vol. of the patient's serum + 1 vol. of the bacterial suspension.

After incubation of these mixtures at 37° C. for 15 to 20 minutes opsonic films are prepared and the phagocytic intake in each is counted. The ratio of the count obtained in mixture (*a*) to that in the control mixture (*b*) will give us a value for the "leuco-phagocytic efficiency" of the patient's blood. The ratio of the count obtained in (*c*) to that obtained in (*b*) will give us the *opsonic index* of the patient's serum. And, by putting up one more phagocytic mixture, in which both washed corpuscles and serum are derived from the patient's blood we may obtain also—by comparison with the count obtained in mixture (*b*)—a value for the total *phagocytic index* of the patient's blood. Where this "chiastic test" is carried out we apply the same working rule as was suggested above—viz., that if the leucocytic efficiency of the patient's blood is reduced to one-third or less of that of the normal blood, he is incapable of making immunising responses, and stands in need of immuno-transfusion.

In conclusion, we may perhaps recall Sir Almroth Wright's dictum, quoted in the first paragraph of this paper, that immuno-transfusion commends itself especially when all that the surgeon can do has been done. If a large abscess remains undrained, or tissues are retained which are so extensively infected as to flood the blood-stream continuously with overwhelming doses of bacterial toxins, we cannot expect to save the patient by a vaccine or by immuno-transfusion—or, indeed, by any method.

Choice of a Donor.

The requirements of immuno-transfusion do not differ from those of simple blood transfusion in this respect. For both purposes we employ a healthy individual, free from syphilitic, malarial, or tuberculous infection, having first determined that his or her blood is compatible with that of the patient—that is to say, that his or her red corpuscles fail to agglutinate when mixed with the serum of the patient. To test this we have only to obtain a very small drop of blood from the donor's finger, dilute it with three or four times its bulk of salt solution and mix with it a small drop of the patient's serum. If after three or four minutes the mixture still remains a homogeneous emulsion of corpuscles, we judge the donor's blood to be compatible with that of the patient; if, on the other hand, the red corpuscles have run together into clumps easily visible to the naked eye, we reject that donor and test another.

If circumstances prevent our thus matching the donor's blood directly against the patient's serum two courses are open to us. We may either employ any donor whose blood conforms to the characters of group 4 (Moss[*])—for the red corpuscles of this type of blood are not agglutinated by any normal serum—or, where it is known that the patient's blood belongs to a particular group, we may seek for a donor whose blood is of the same group. Although in theory there is nothing to choose between these two practices, it has been stated by some who have had considerable experience of transfusions that febrile "reactions" are less commonly seen after the injection of blood from donors of the same group as the patient.

Before leaving this subject it may be well to mention that we have sometimes heard doubt cast upon the necessity for testing the blood of the donor as to its "compatibility" with that of the patient. Medical men naturally hesitate to report unpleasant or disastrous results of treatment, with the result that it may occasionally happen that the dangers attendant upon a certain course of action are not widely realised. Transfusion of blood incompatible with that of the recipient patient is perhaps a case in which dangerous reticence has been practised. We therefore think it well to record the following experience. A patient who had twice been transfused with blood from compatible donors and had borne the transfusions well, required a third transfusion. As soon as the injection began—before even 20 c.cm. of blood had been given—he became very uneasy, complaining of severe burning pain all over. The breathing also became difficult. As these symptoms increased to an alarming extent and were accompanied by some collapse the injection was discontinued. The patient gradually recovered. On inquiry being made as to the cause of this untoward occurrence it transpired that in determining the group of two possible donors, the labels on the two samples of blood had been inadvertently transposed, with the result that a donor whose blood was incompatible with that of the patient was chosen. The conclusion that the symptoms observed were due to this incompatibility of the blood injected was substantiated by the fact that, a week later, after a trial injection of 20 c.cm., the patient was again transfused with blood of a compatible type and showed no symptoms either at the time or subsequently. We have had reported to us also another case where serious symptoms followed the injection of blood taken from a donor of incompatible group. We are not, however, in possession of complete details.

Immunisation of the Donor's Blood.

A word of introduction will perhaps help to explain our procedure. The old idea that a patient suffering from a very severe microbic infection might derive benefit from the transfusion of blood taken from a patient who had recently recovered from a similar infection has been revived during the last few years in a slightly modified form. Instead of taking the blood from the convalescent patient it has been proposed to take it from a healthy donor previously immunised by one or more inoculations of vaccine—either a vaccine prepared from the microbe infecting the patient, or the homologous stock vaccine. The assumption is made, of course, that the blood of the donor, when withdrawn for the transfusion, is richly endowed with "antibodies" having a specific (and destructive) affinity for the microbe infecting the patient. Cases treated in this way have been reported by Hooker,[3] Libman and Ottenberg[4] (1917), Fry,[5] Little[6] (1920). The chief defect of this method is that the donor has been inoculated without any previous test, and apart from such test it is impossible to say that the blood which has been used for the transfusion is in any sense immunised blood. It will be a matter for future investigation whether blood obtained in this way, and verified to contain protective substances, may not find useful application in the treatment of protracted septicæmic infections—e.g., cases of malignant endocarditis.

---

[*] The method of ascertaining the blood group of any individual has been described by many authors; the reader may be referred to papers by Lee: Brit. Med. Jour., 1917, ii., 686; or Fleming and Porteous, The Lancet, 1919, i., 973.

The method of immuno-transfusion suggested by Sir Almroth Wright differs in several respects from that to which we have just referred. It took origin in the observation that the addition of an appropriate quantum of certain vaccines to blood in vitro, or in vivo, resulted in the elaboration of protective substances (as shown by increased bactericidal as well as opsonic power) *within a period of a few minutes to an hour or so.* These protective substances were derived from the leucocytes and were non-specific in character—i.e., they were effective upon all the ordinary pathogenic microbes—and not only upon that one species with which the blood had been vaccinated. It was this non-specific and rapidly evolved immunity which Sir Almroth Wright proposed to exploit for the purpose of immuno-transfusion.

We come now to the practical application of this proposal. Originally, as described by Sir Almroth Wright, we took a preliminary sample of the donor's blood and carried out with it a "vaccine-response test" in order to determine the dose required to evoke an optimum immunising response. Having obtained this information we drew off the half litre or more of blood required for the transfusion, added to it the appropriate quantity of vaccine and, after incubation for an hour, injected it into the patient. Early in 1922, with the gradual development of improved methods of testing the bactericidal power of the whole blood, we learned that immunisation was obtained somewhat more regularly, and in larger measure, if we incorporated the vaccine into the donor's blood in vivo (by intravenous inoculation) and waited one to two hours before drawing off the blood in bulk. More recently still we have ascertained that the subcutaneous inoculation of certain vaccines (staphylococcus, streptococcus, and *B. typhosus*) evokes within four or five hours in normal persons just as striking an immunisation of the blood as is obtained by intravenous inoculation.

† Tests put up in duplicate. ‡ Tests put up in triplicate.

The experiments shown in Table I. will serve to illustrate this immunisation. In experiments 1 to 7 a series of normal individuals were inoculated subcutaneously with doses of vaccine as shown in the table. Samples of blood were taken from a vein in each case before the inoculation and at stated intervals after. Each sample was at once defibrinated. In order to compare the bactericidal power of the bloods taken before and after inoculation several 50 c.mm. volumes of each were mixed with 2·5 c.mm. volumes of a graduated series of dilutions of a staphylococcus broth culture, and then transferred to "slide cells," as described by Wright, Colebrook, and Storer.[2] After 24 hours' incubation in these cells at 37° C. the number of colonies which had grown in the blood was counted. They may be taken to represent the number of cocci which survived the bactericidal effect of the blood. Comparison of the number of these survivors with that of the cocci originally implanted, as shown in the table, will indicate the bactericidal effect achieved by each sample of blood.

The experiment given in Table II. is also quoted in order to illustrate a somewhat different procedure for comparing the bactericidal power of the bloods taken before and after inoculation. In this experiment mixtures of each sample of blood with living Staphylococci were prepared, as in experiments 1 to 7, but instead of incubating them for 24 hours in slide cells, each mixture was "explanted," after two hours' incubation, into melted agar at 47° C. and the latter poured into sterile Petri dishes. The advantage of this procedure is that it allows us to test the hæmo-bactericidal power upon microbes such as *B. typhosus* which do not grow into visible colonies in blood. We are indebted to our colleague, Dr. H. B. Maitland, for the record of this experiment and of experiments 3 and 4 above.

TABLE II.

Experiment No.	Blood of—	Vaccine and dose.	No. of microbes implanted in each sample of blood as shown by agar counts.	No. of colonies which grew in the agar infected with blood taken— Before inoc. Staph.	Before inoc. *B. typh*	5 hr. after inoc. Staph	5 hr. after inoc. *B. typh.*
8	J. K. C.	Stock *B. typh.* 100 mill.	297 133	165 51		91 31	
			724 238		160 73		40 35

If we total up the figures obtained with Staphylococci and *B. typhosus* respectively in this experiment, and work out the ratio of the number of survivors to the number of microbes implanted in the blood, we get the following result :—

	Staph.	*B. typh.*
With blood taken before the inoculation ..	50 %	24 %
,, ,, ,, 5 hrs. after ,, ..	28 %	8 %

By these and other similar experiments it has been demonstrated that :—

1. Within one to five hours after the subcutaneous inoculation of a normal individual with appropriate

doses of staphylococcus, streptococcus, and *B. typhosus* vaccines, the blood acquires a considerably increased hæmo-bactericidal power.

2. This increased power exerts its effect non-specifically. In experiments 5, 6, and 8 in which *B. typhosus* vaccine was inoculated, and also in experiment 7 in which streptococcus vaccine was employed, the blood shows increased power of killing Staphylococci. (Possibly this general statement will need some qualification. In one experiment—not quoted—after an inoculation of staphylococcus vaccine the blood showed only a very slightly increased power of killing *B. typhosus.*)

3. The development of the increased hæmo-bactericidal power seems to vary with the dose of vaccine. Using 1000 millions of staphylococcus vaccine, satisfactory results were obtained in every instance four or five hours after the inoculation, and in one case (but not in others) so soon as two hours after. (Possibly a somewhat smaller dose of this vaccine would immunise the donor as effectively and more rapidly.) When 250 millions of *B. typhosus* vaccine was inoculated there followed a period of one and a half hours at least in which the hæmo-bactericidal power to staphylococcus was diminished.

4. The increased hæmo-bactericidal power following inoculation has generally disappeared after 48 hours—sometimes after 24 hours. This is not shown in the experimental records quoted, but in one of them (experiment 7) it will be seen that after a very small dose of streptococcus vaccine the increased power was already waning after five hours.

In consideration of these findings we have, for the past few months, adopted the routine procedure of inoculating donors subcutaneously with 1000 millions of our stock staphylococcus vaccine,† and drawing off the blood after a period of four to five hours. Typhoid vaccine (100 millions) is apparently just as effective, but will occasionally induce a slight febrile disturbance in the donor.

Considerations which Favour the Use of Defibrinated Blood Rather than Unaltered Blood or Blood in which Clotting has been Prevented by the Addition of Decalcifying Agents.

In the course of recent work which will shortly be published,[7] the present authors have shown that an addition of sodium citrate, ammonium oxalate, or sodium phosphate to normal blood, in amount sufficient to prevent clotting, considerably reduces its power to kill Staphylococci and Streptococci, this result being brought about by impairment of some of the functions of the leucocytes. The same result is obtained with blood taken from an individual who has made an immunising response to vaccine. In view of this reduction of its bactericidal efficiency we concluded that blood to which decalcifying agents had been added should not be employed for the purpose of immuno-transfusion.

We come, then, to the question which of the two alternatives is best suited to this purpose, unaltered blood or defibrinated blood. Evidently unaltered blood has this in its favour, that it has lost none of its leucocytes; in defibrinated blood, however carefully the fibrin meshwork is collected, we never find more than 70 to 75 per cent. of the number present in the unaltered blood. It would seem, however, that this loss of 25 to 30 per cent. of its leucocytes makes but little difference to the bactericidal power of the blood. In the following table are set out the results of several experiments in which comparison was made between the bactericidal effects obtained with unaltered blood and defibrinated blood respectively.

In these experiments 50 c.mm. volumes of blood were implanted with 2·5 c.mm. volumes of a diluted broth culture of Staphylococci, and incubated for 24 hours in slide cells. The number of cocci which survived and grew out into colonies was as shown in Table III.

TABLE III.

Exp.	Blood of—	No. of Staph. implanted in each sample of blood.	No. of colonies which grew in the—	
			Unaltered blood.	Defibrinated blood.
• 1	A. F.	460	(3 tests) $\left.\begin{matrix}2\\7\\11\end{matrix}\right\}$ aver. 6·6	5
2	A. F. H.	318	(2 tests) $\left.\begin{matrix}3\\1\end{matrix}\right\}$ aver. 2	3
3	L. C.	130 approx.	0	2

It would appear, then, that from the point of view of providing the patient with efficient leucocytes it matters little or nothing whether we use unaltered blood or defibrinated blood for immuno-transfusion. Nor is there anything to choose between these alternatives in respect of the bactericidal power of their *fluids*. When the blood fluid has the power to kill Staphylococci this is found to be the same for the plasma and the serum.

When, however, we look at the question from the standpoint of ease and convenience in carrying out the transfusion our choice is no longer in doubt—we elect to use defibrinated blood. By doing so—in the manner to be described in the next sections—we avoid all difficulties which arise from the tendency of the unaltered blood to clot (and it follows that we can carry out the injection into the patient as slowly as we wish); we avoid the dissecting out and exposure of the veins of either donor or patient; and, finally, we do not require to have the donor in the immediate vicinity of the patient—indeed, he may be miles away. In a word, all the advantages which have been claimed in the past for the transfusion of citrated blood can now be claimed for the use of defibrinated blood: the one is just as easy as the other.

A theoretical objection to the use of defibrinated blood may occur to the reader. Remembering that for a short time after it is collected defibrinated blood contains active fibrin ferment (as shown by the rapid clotting of fresh blood to which a drop of defibrinated blood has been added) he may fear that the transfusion of blood of this kind might lead to intravascular clotting. This, however, is not the case, for it was established many years ago that fibrin ferment is quite inactive upon blood in vivo. The experiments which proved this were conducted, of course, upon animals, but there is no reason to doubt that they apply equally to man. As a matter of fact, transfusions of defibrinated blood have often been successfully carried out in the past (Bischoff, Halstead, Moss, and others); and during the past 12 months on more than 100 occasions by our colleagues and ourselves without the occurrence in any case of symptoms pointing to intravascular clotting.

(*To be concluded*)

ROYAL SUSSEX COUNTY HOSPITAL.—On Dec. 13th Lady George Nevill opened the new orthopædic and X ray department at this hospital. The department was presented by the Joint War Committee of the British Red Cross Society and the Order of St. John of Jerusalem, and others, the main equipment having been provided by the transference of the valuable appliances from Lady George Nevill's war hospital at Hove. The announcement was made by Sir William B. Gentle that a sum of money would be devoted to presenting to the hospital a cardiographic department and to endowing the maintenance of the plant for the purpose, to be called the "Lord George Nevill Department."

† Retailed by Messrs. Parke, Davis and Co.

ON THE USE OF OPIUM IN CARDIAC DYSPNŒA.*

BY CLAUDE WILSON, M.D. EDIN.

IN an extensive, though hardly an exhaustive, search through the literature of the subject, sundry notes have been found recalling the value of opium in various forms of cardiac distress, and a statement by Mackenzie that small doses at bedtime may avert attacks of cardiac asthma, but I have failed to find a record of cases analogous to those which I subjoin, while the fact that Prof. J. C. Meakins does not allude to opium at all in his recent B.M.A. lecture, at Dundee, on the Treatment of Dyspnœa in Cardio-Vascular Disease,[1] would seem to imply that its importance is not generally recognised.

Two Types of Dyspnœa.

Dyspnœa of cardiac origin may be divided clinically into two distinct types: Firstly, the ordinary dyspnœa as an immediate consequence of exertion is present in more or less degree in every case of heart disease. In intensity it may vary from a trifling augmentation of the ordinary breathlessness that any healthy subject may get on undertaking unusual effort, to an extreme condition when slight movements in bed produce breathlessness. Its mechanism is simple and well understood, and its amelioration depends on such general measures as may improve the cardiac condition, with additional relief from oxygen inhalation in extreme cases. Opium is in this condition a somewhat dangerous drug. In the lesser phases it is seldom called for; while in extreme degrees, though it may produce restful sleep, and consequent improvement, its administration may terminate in euthanasia. Still, there are cases where the risk may seem justified.

The second division of cardiac dyspnœa—quite different from the first, though commonly overlapping it—comprises two sub-types, both of them paroxysmal in incidence, seldom initiated, though often revived by immediate effort, and certainly differing in mechanism from the ordinary dyspnœa of exertion. How far the ætiology of these—Cheyne-Stokes breathing and cardiac asthma, so different in clinical picture—may possess a common factor, is for physiologists to determine; but that there is a common factor seems likely from the fact that the therapeutics of each is so similar. Oxygen administered in either case, and in sufficient quantity, will not only very generally give speedy relief, but if continued long enough will often terminate the vicious circle which has somehow been established and the normal respiratory rhythm will reassert itself. But, apart from well-equipped institutions, it is only in exceptional conditions that oxygen is quickly available —at any rate, in sufficient quantity to allow of anything like its adequate exhibition, and the object of this communication is to call attention to the fact, which does not appear to be widely known, that opium is not only in many cases an efficient substitute, but perhaps the treatment of choice. The method of administration has generally been hypodermic, not only to secure a more rapid effect, but because the gastric functions in these cases are usually so much disturbed that absorption by the oral route is uncertain. Morphine and omnopon have proved equally efficacious hypodermically, and occasionally tablets have been supplied to a patient to dissolve under the tongue.

In both of these varieties of paroxysmal cardiac dyspnœa, the cases in which I first used opium were such as presented symptoms so distressing and so alarming that the risk of death while under the influence of the narcotic appeared to be not only justifiable but a necessary one to incur. Since then I have used the drug in many cases of Cheyne-Stokes breathing, and in a still larger number of instances of cardiac asthma, and though the number is not sufficient to generalise upon, I have almost invariably found that a very moderate dose, and often a very small one, not only restored the normal respiratory rhythm—sometimes very quickly—but that orthopnœa was lessened or abolished, that the fluid exuded into the bronchi in the asthma cases was absorbed, and that these improvements endured for periods varying from days to months. Of course, general treatment, including restriction of effort and often digitalis, has been resorted to in each case between the attacks, but details of such measures are omitted from these notes, the object of which is to show the effect of opium on the paroxysms.

Opium in Cheyne-Stokes Respiration.

Cheyne-Stokes respiration varies from a slight undulation of the respiratory rhythm, occurring sometimes only during sleep, and seldom observed unless carefully looked for, to a rare and extreme degree in which the suffering from air-hunger during the height of the active phase becomes almost unbearable. My first was a case of this kind—an old gentleman of 94 years, who had suffered from symptoms of cardiac failure for some years, and had several times had mild bouts of Cheyne-Stokes breathing. On this occasion I called in by chance about noon to find him leaning forwards with staring eyes and open mouth, grasping the arms of his chair and gasping for breath. The gasps reduced in volume and intensity and died away, and there followed a few moments of apnœa when the patient leant back and closed his eyes. Then again began the active phase, and the eyes opened in terror and appeal for relief from the oncoming agony. I had morphine with me and injected a quarter of a grain; then left, paid a neighbouring visit, and came back 20 minutes later with a second dose ready to administer. But I found the sufferer leaning back on his cushions asleep, and breathing quietly and regularly. He slept for four hours, woke up and asked for tea. When I saw him later on he was in bed, feeling quite comfortable, and there was no further attack of Cheyne-Stokes for many weeks. By that time the nurse had both oxygen and morphine available, but the latter was never required, while the first was used but sparingly. He never had another severe attack.

I have seen but two cases of Cheyne-Stokes where the active distress of dyspnœa called for immediate relief, but I have given morphine to several patients for the relief of other symptoms, who, at the time of the injection, showed the respiratory undulations of minor Cheyne-Stokes; and I think in every case, as drowsiness supervened, the abnormal rhythm has been replaced by regular breathing.

In one case of advanced heart failure, both opium and oxygen failed to abolish the periodic rhythm, at any rate, more than temporarily. Oxygen, except for occasional short spells, seemed to worry the patient, but morphine brought sleep, relieved the orthopnœa, and reduced the Cheyne-Stokes rhythm from a major to a minor type. During the sleep induced by opium a mild stream of oxygen was allowed to play below the mouth and nostrils, and the breathing became so nearly regular that the wave character had to be looked for to be recognised, though with slight exertion on waking it became obvious. These conditions continued for two or three weeks. Oxygen was later on given pure or in high concentration from a nitrous-oxide mask, and by catheter in mouth or nostril during sleep for hours at a time. It seldom modified the wave character of the breathing, and never more than temporarily, while an attempt to influence the reflex by rebreathing, thus supplying a mixture of oxygen and CO_2, was resented by the patient, who knocked the mask away with his hand. As general signs of cardiac failure increased, and a fatal issue became obvious, morphine, the only drug which was found to give quiet sleep, was pushed till, near the end, when the Cheyne-Stokes character had assumed a major phase, and became a matter of obvious distress, 1 gr. doses were given every four hours. Under these large doses the wave character disappeared, and during the last 12 hours of life the breathing was regular in rhythm. Mucus, which during the Cheyne-Stokes phase had never caused râles, now accumulated in the lungs, and death appeared to be due to a lack of aeration, from semi-drowning.

* Being one of the opening papers in a discussion on Cardiac Dyspnœa held at the Section of Therapeutics of the Royal Society of Medicine on Dec. 11th, 1923.

[1] Brit. Med. Jour., June 23rd, 1923.

Opium in Cardiac Asthma.

In cardiac asthma, though attacks vary much in intensity, the urgent call for relief of distress is often much more imperious than is common in cases of Cheyne-Stokes. I cannot doubt that morphine must frequently have been used in these circumstances, and that many practitioners must be aware of its signal value, but apparently very little has been put on record, though its effect in cases of "renal asthma" is, I believe, recognised. In two of the cases subjoined there was obvious Bright's disease, but it will be noted that the attacks of "asthma" did not develop until a definite cardiac element supervened.

My first case was recorded.[2] I append an abstract:—

CASE 1.—A gouty and nephritic retired clergyman of 71 years; breathless on mounting stairs for some years. Heart sounds pure, pulse regular—80–90. B.P. (systolic) 160–180. Sudden angina a month ago, with one or two recurrences. Other usual signs of cardiac failure. Without warning or obvious cause, one night, at 1 A.M., cardiac asthma suddenly developed. Arriving at 1.40 I found the family and two nurses assembled in the room or just outside anticipating death. The patient was raised on a pile of pillows; face and neck congested and cyanosed; hands and forearms cold, pale, and clammy; respirations 48 per minute—gasping; and pulse uncountable and very irregular. Heart in condition of "delirium cordis," no murmurs. Coarse mucous râles all over both lungs. 1.45 A.M.: Morphine gr. 1/3, with strychnine and digitalin, āā gr. 1/60, injected subcutaneously and oxygen administered from cylinder which had been got in for occasional relief of ordinary dyspnœa. 1.55: Aspect easier; respirations 36. 2.10: Comfortable; respirations 28; pulse about 100 and nearly regular. Slept or dozed all night. 8.0: Moving easily in bed without assistance. Pulse 82, regular; respirations 18; no râles anywhere.

Here we have obviously to do with a case of temporary auricular fibrillation, and I have seen other cases since in which the first attack of cardiac asthma apparently coincided with the onset of fibrillation. The therapy in this case was mixed, and the satisfactory result may have been due to more than one element; but subsequent experience makes me feel very sure that the most important factor was the morphine.

CASE 2.—Is of a different character. A spare ascetic man of 64, with a greatly enlarged heart and puffing murmurs accompanying both sounds, but not replacing either, and heard all over the heart. Pulse about 80 and regular. Blood pressure: systolic, 145; diastolic, 70. No albuminuria; attack of cardiac asthma of moderate severity developed suddenly about 2 A.M. When I saw him he was propped on pillows and very restless. Respirations 40; pulse about 100; frequent extra-systoles. Moist râles all over both lungs. Morphine gr. ¼ soon procured easier breathing, which in half an hour came down to 22 per minute, and the râles disappeared. He shortly lay down and went to sleep, and woke up quite comfortable in the morning. Similar attack a week later followed a similar course. It will be noted that no other drug was used, and that the rapid breathing, the orthopnœa, and the râles, along with the great restlessness and appearance of distress, subsided quickly under the influence of a small dose of morphine.

These attacks occurred in November, 1921, but only once since has he had an attack of the asthmatic type, and that a slight one, which again yielded promptly to the same treatment.

CASE 3.—An old lady of 76. Heart disease for years and fibrillating for over a year, but doing well on digitalis. No albuminuria; sudden attack of cardiac asthma about 10 P.M. without obvious cause. Urgent summons by telephone. Found patient propped on pillows, fighting for breath. Respirations 42; pulse about 90 and fairly regular; râles all over both lungs. Morphine gr. 1/6 injected, and in 20 minutes the respirations were down to 30. The discomfort gradually lessened, and in an hour and a half the patient went to sleep and slept well till morning, when she was found lying flat with two pillows. Pulse 74 and apparently regular; respirations 20 and no râles. That was three months ago and there has been no return of dyspnœa.

CASE 4.—A banker, about 54; renal disease of four or five years' duration. Blood pressure: systolic, 240–270; diastolic, 120–160; going about his business and sleeping well. Suddenly, about 5 P.M., developed auricular fibrillation and an attack of cardiac (and ? renal) asthma; orthopnœa; leaning forward in chair gasping. Pulse very rapid and irregular; respirations very rapid, about 45; râles all over both lungs. Morphine gr. 1/3, gradual relief; slept well. In morning was found sleeping with two pillows only. Respiration easy; no râles; pulse got steady and slow under strophanthus. This was four months ago and there has been no further attack of asthma, though ordinary dyspnœa is present on slight exertion, while orthopnœa and insomnia are always present unless controlled by opium. Morphine or omnopon (gr. 1/3) always gives a good night and abolishes the orthopnœa, and this is followed by two or three equally good nights. Then comes the gradual return of insomnia and orthopnœa, till on the sixth and seventh nights he sometimes fails to get any sleep at all, and lies propped up on pillows. Then he has another hypodermic, gets three or four good nights, and the process is repeated.

The above four cases are examples of cardiac asthma in somewhat different types of heart disease, in all of which brief notes were made at the time. They are sufficient to illustrate the effect of opium in these cases; but I have seen several others in which the same marked benefit has followed the same treatment; and such is my confidence in the happy effect, that were I ever to develop such a condition myself I should immediately inject morphine, were I well enough to do so.

Conclusion.

Since I wrote this paper it has been pointed out to me that in all the four cases recorded above mucous râles were noted, and indeed I purposely emphasised this element to show that opium was not, as used to be thought, contra-indicated in such cases. But the suggestion has been made that these cases may be properly described as acute pulmonary œdema, in which morphine seems now to be the accepted treatment. I would, however, submit that my cases are properly described as cardiac asthma. Minor cases occur with few, if any, râles; the cases are obviously of cardiac origin; the paroxysms, which commonly occur at night, are of asthmatic type; there is always orthopnœa; the dyspnœa, I feel pretty sure, precedes the moist râle; and the hyperpnœa is generally far in excess of what the bronchial exudation will account for.

Postscript.

In Sir James Mackenzie's book on "Angina Pectoris," published after this paper was completed, I find the first definite statement that a hypodermic injection of morphine may bring relief in cases of cardiac asthma—"as in the common forms of asthma"—the suggestion being that its action is the same in both cases. Of this I am not very sure. But another statement which appears to me to be of great interest follows (p. 109):—

> Many years ago I had an opportunity of seeing a number of these cases, and observed that before they went to sleep they had a tendency to Cheyne-Stokes breathing, and in one or two instances the attacks of asthma came on at the end of a long period of apnœa. It occurred to me that probably the cardiac asthma was merely an advanced stage of Cheyne-Stokes respiration. A careful study of my cases in subsequent years has convinced me that this is true, although I am not prepared to say that it is true in every case.

Though I have seen both types of dyspnœa in the same patient, I have not personally noticed this close conjunction, but I can well believe it is so; and the suggestion would seem not only to link up the two conditions, and help to explain the success of a common therapy, but also to throw light on the differences in the clinical picture. In Cheyne-Stokes breathing it is, I believe, generally accepted that the phases depend on alternate excess of oxygen and CO_2 in the blood: and, so far as I have noticed, there are few, if any, râles present. With the exudation that occurs in cardiac asthma—if of more than very short duration—there will be a physical impediment to hyperoxygenation, and consequently the hyperpnœic phase will persist, and not become automatically limited.

Clinical and Laboratory Notes.

THE TEMPERATURE OF THE SKIN OVER LIPOMATA.

By Harold Burrows, C.B.E., F.R.C.S. Eng.

It is common knowledge that when a fatty tumour is palpated a sensation of fluctuation may be produced which is indistinguishable from that caused by a collection of fluid. A confused or mistaken diagnosis may arise from this cause if on account of its depth or for any other reason the lipoma cannot be readily recognised as such by inspection. For this reason any additional means which will help us to distinguish a fatty tumour from other swellings will be acceptable, and it is on this account that I wish to call attention to the fact that the temperature of the skin over a lipoma is constantly reduced when a comparison is made with due attention to symmetry and conditions of exposure. The relative coolness of the skin overlying a lipoma, as compared with that of a similar area on the opposite side of the body, is so considerable that it can be appreciated readily by palpation with the palm of the hand; and as a diagnostic aid is reliable.

As the test is by contrast only, care, of course, must be taken to make the comparison a proper one both as regards the parts which are compared and the time during which they have been exposed to the air prior to the examination, and it is especially to be remembered that appreciable differences of surface temperature are noticeable in different parts of the same limb. For example, the skin over the patella, in health and in natural conditions, is cooler than that over the quadriceps muscle; while the back of the calf is distinctly warmer to the touch than the skin where the tibia is subcutaneous. The reason for these differences is obvious enough, but they must be borne in mind when inferences are to be drawn from the results of palpation.

I suppose some apology ought to be made for calling attention to such a simple diagnostic aid. Probably generations of surgeons have employed it. Nevertheless I have failed to find any reference to the matter in print, and every help towards a correct recognition of the nature of a tumour may be of value.

Portsmouth.

A CASE OF RUPTURE OF THE HEART.

By J. Knox Thompson, M.B., B.Ch., B.A.O. R.U.I.

A male, aged 71, an inmate of Belmont-road Institution, Liverpool, complained on Oct. 12th last of gastric symptoms and debility. I sent him into hospital on that day, and he remained there until the 16th. When he got up on the 17th he asked to be allowed to go back to the house as he was feeling better. About midday he was sitting on a chair in the tailor's shop when he suddenly collapsed and died. At the post-mortem examination on the morning of the 18th I found the pericardial cavity filled with blood-clot, which was adherent to a small linear area on the anterior surface of the left ventricle, and when the clot was removed the breach in the wall of the left ventricle was marked by a few threads of clot adhering to it. The large blood-vessels and the valves were found to be intact, and no aneurysm was present. The heart was about normal in size, but the wall of the left ventricle was perhaps a shade yellower than normal. The rupture was not a straight cut through the wall; the channel was zig-zagged between muscular bundles on its way from the cavity of the ventricle to the surface of the heart, and the aperture was narrower on the inner side than the outer side. The liver was hob-nailed, and there was some sclerosis of the kidneys. The brain was normal.

ROYAL SOCIETY OF MEDICINE.

Special Discussion on Chronic Abdominal Pain in Nervous Women.

A special discussion on this subject was held on Dec. 17th, Sir William Hale-White presiding.

Introductory Remarks.

Dr. R. Hutchison said that the cases under discussion did not exemplify any definite disease, but constituted rather what was generally known as a "clinical syndrome." He had described them as those of the chronic abdomen, and Dr. H. Cabot[1] had lately spoken of them as "those painful women." It had been difficult to decide on a title for the discussion; the one eventually chosen implied that the patient was a woman who complained of constantly recurring abdominal aches and pains, often referred to the right iliac fossa. She suffered also from dyspepsia, was profoundly constipated, and often passed mucus in the motions. Her menstrual functions were often deranged. In addition there were remote symptoms of various sorts—headache, "rheumatic" pains, tiredness, nervousness, and insomnia. The mental aspect of the case was often even more pronounced. The patient was depressed, introspective, self-centred, and peevish; was always dwelling upon and magnifying her symptoms, and had an insatiable craving for sympathy. She was a connoisseur in doctors, specialists, and "treatments"; she had often acquired the operation habit, and although any new therapeutic plan usually relieved her for a time the relief was always short-lived. The patient was undernourished, often of a bad colour, and exhibited a greater or less degree of visceroptosis. The stomach was usually atonic, and the gastric secretion rather subacid. There was delay in the passage of the contents through the intestine, especially in the pelvic colon. Displacements of the uterus were common, but the other organs usually presented no signs of disease.

The patient usually belonged to the upper classes; she was rarely met with in hospital practice. She was generally unmarried, or if married, childless, and there was often in her immediate environment some relative who ministered to her constant demand for sympathy. She would have seen many doctors, had probably had several operations, and would have undergone a great many more or less elaborate and expensive treatments without permanent relief to her symptoms.

Dr. Hutchison suggested that the discussion should be restricted to certain definite lines of inquiry, as follows: (1) To what extent were the abdominal pains in these women due to an organic cause, such as dragging upon nerves, kinks, and so forth? The results of surgical treatment should help us here. If the pains could be definitely and *permanently* relieved by operation, it was presumptive evidence that its cause was organic. (2) If not always or not entirely of organic origin, what was the cause of the abdominal sensations? Were they due to a low threshold for pain in these patients so that slight discomforts became magnified in consciousness, and, if so, how was this brought about? Or were they hysterical, a form of "convenient arrangement" as Adler had called it, the result of a subconscious desire for sympathy? The psychologists should be able to throw light on this aspect of the subject. (3) What was the relation of the physical to the mental state in these patients? Was the mental side of the case the result of the physical or was it primary? For example, was it the depressed emotional state in these patients that caused atony of the stomach and intestines, or did visceroptosis and atony lead to emotional depression? If the latter, why did many women with visceroptosis fail to exhibit any mental symptoms? The part played by the patient's environment in the development of the mental symptoms had also to be considered. Did these symptoms only appear in an atmosphere of idleness and aimlessness, or where there was an excess of sympathy on the part of relatives? It would be profitable to inquire also to what extent, if any, the artificial menopause which many of these patients had suffered was responsible for some of the mental symptoms. Gynæcological experience would be of value on this point. Or had the mental trauma inflicted by repeated abdominal operations anything to do with them? (4) As regards treatment, he thought there would be agreement as to the general medical lines to be pursued, especially as to the importance of recognising these cases in their initial stage, of subjecting them to a suitable fattening cure, with the provision afterwards of an efficient abdominal support, of avoiding drastic aperients, and so on. As regards drug treatment, everyone would admit the utility of the bromides, but he would like to raise the question whether anything could be done for these patients by the use of endocrine preparations. Here he confessed himself highly sceptical. As to surgical treatment, what needed discussion was the degree of *permanent* benefit to be obtained from the fixation of organs, and especially from colopexy. Finally, there was the question of psychotherapy. We wanted to know to what extent psychotherapists found these patients benefited by psychotherapeutic treatment, and what form of it was best suited to their needs.

---

[1] Medical Clinics of North America, March, 1923.

The Tired Mother.

Dr. J. S. **FAIRBAIRN** said that his experience of abdominal women did not differ from Dr. Hutchison's, except in a few minor points. Besides spinsters or childless married women, he saw many with small or large families and some who could not be said to be comfortably off, with symptoms like those described. In addition to a general abdominal enteroptosis, there was, in women who had borne children, also some degree of pelvic floor weakness, but with subjective sensations of prolapse out of all proportion to the degree of prolapse actually present. Laxity of the abdominal and pelvic floor muscles though common was not invariably present. Constipation and mucous colitis were also frequent. These patients suffered also from over-doctoring and especially from having had fancy operations and fancy treatment practised on them. It was difficult to form a just perspective of the physical and psychical elements in these cases. They were regarded from almost as many aspects as there were healers of the body. The mechanical school would find an explanation in some usual or unusual position of the uterus or other organ; the chemical school would look for and find an auto-intoxication or some disturbance of metabolism; the Freudian psychologist would discover some repression or conflict. As to the mechanical school, their vision was confined to the anatomical position of organs and was blind to physiology. That school was the curse of gynæcology and was represented by those who did constant fixation operations and hysteropexies; nowadays, however, most gynæcologists admitted the large part played by the mental factor in making women over-sensitive to bodily sensations of a disagreeable kind. Spinsters and childless married women had, owing to our social system, been denied the exercise of the sexual and reproductive function and that in itself must have far-reaching effects, especially if there was no adequate complemental interest to take its place. But there was also another class, the women with children but with little help in caring for them. Long-continued impressions of the same kind without sufficient relief or distraction by other impressions of a totally different type were especially productive of fatigue. For example, the tired mother of four or five young children with little or no help in the house had few holidays, and they were but a change from her own house to rooms at the seaside, where escape from the children was even more difficult than at home. If in addition she had anxiety and sleepless nights nursing sick children or a sick husband, all the factors, mental and physical, were present for the production of chronic fatigue of the higher centres. Another type was that of the woman who after bearing her first child was described by her distracted husband as "never the same woman since her baby was born." She was of the disgruntled order, had abdomino-pelvic pains of varied kinds, and was incapable of exertion and particularly of doing anything she did not want to do, because it always aggravated her troubles. Such patients seemed to divide their anxieties between themselves and their one child, and though Dr. Fairbairn often advised another child, the advice was usually badly received. His experience led him to think that incapacitating abdomino-pelvic sensations of the same type might result in spinsters or childless married women from lack of complemental interests to make up for the absence of sexual and reproductive function, and in married women with children from mental fatigue, and further, that though the incapacity is often determined by muscular weakness it might be present without it. The gynæcologist had no statistical evidence of the proportion of women in whom the uterus lay backward, and hence its ætiological moment could not be estimated accurately. Many women had the uterus lying back with no symptoms, and many women with what was thought by the mechanistic school to be the symptom-complex of that position had the uterus in the normal anteverted position. These women for their restoration to efficiency required reassurance, relief from exacting duties, or fresh interests. The early years of the war with its new impressions temporarily cured many. Operations gave temporary benefit because rest and relief from everyday duties were then secured and an operation had an enormous suggestive effect. Physical exercises and improvement of the physique appeared to Dr. Fairbairn all-important. There was no royal road or dramatic cure, but much might be done by those prepared to give the necessary time and individual attention required.

A Neurological Classification.

Dr. J. **COLLIER** said that learned neurologists in the past had made an attempt to divide these cases into the following four groups: (1) Those in which the condition is without any other basis than the hysterical state; (2) those in which the condition includes a delusion of the insane type; (3) those in which the natural physical state is one of continual vigilance, apprehension, and fear and attention as regards bodily health; and (4) those in which there is a primary and real bodily cause for the trouble. The three last-named groups might overlap, but the hysterical group was, he submitted, quite distinct from the other groups. In his opinion the majority of the cases fell into the last group, in which a real physical cause existed. The hysterical cases were distinguished by the presence of the definite stigmata of hysteria, and however long lasting they were curable; when successfully cured they did not relapse. Dr. Collier quoted as an example a girl, aged 20, at present under his care, who had suffered over a term of years successively from hysterical hemiplegia, severe abdominal pain, vomiting, hæmatemesis, severe general wasting, and marked acidosis. Operation was contemplated, but Dr. Collier, called in at this stage, ordered instead careful watching night and day. It soon transpired that this patient lived much of her time with two fingers down her throat, with which she scratched her lower pharyngeal veins. The discovery of the fraud and the threat of forcible feeding if vomiting continued produced no resentment, but seemed to relieve the patient's mind, and she made a rapid and complete recovery. The most interesting point about this case was the loss of the deep reflexes from the bodily dyscrasia resulting from starvation. The cases with insane delusions were not very common. The group of cases where habitual self-vigilance and anxiety, without adequate cause, was the chief condition present were easy to distinguish. Hereditary and familial tendency was often strong, and an easily excitable temperament was always present. The subjects were usually careful livers, even valetudinarians, and might be able and successful workers. Their especial characteristic was the ease with which their symptoms could be temporarily removed by the assurance of any dominant personality for whom they had liking and confidence. The last group, from their symptoms and signs, impelled the conclusion that there was something wrong with the splanchnic region of the anatomy. It was, Dr. Collier submitted, universally accepted that all consciousness of well-being, all feelings of happiness, joy, and elation, of fear, anger, and sorrow, were derived from sensations in the area of the splanchnic viscera, nose, eyes, and possibly meninges; that these sensations were produced by definite bodily reactions, which could in some instances be perceived and registered by electrical methods. If the bodily reaction which depended upon the functional integrity of the organs in which it occurred did not take place, no feeling rose into consciousness, no emotion occurred. The importance of these emotions as the interests and stimuli of our daily lives was incalculable. Their importance in aiding a healthy action of our vegetative organs were doubtless equally important. Dr. Collier suggested that partial failure of the reactions in the splanchnic organs, and especially disorder in the normal production of these reactions, produced the almost ceaseless abdominal unrest and discomfort, the pain, cramps, disordered action, and secondary anatomical changes which were met with in the disease under discussion. The mental effect of these was immensely more important than that of common bodily disorders of sensation in that the former were disorders of the integral mechanism by which well-being, satisfaction, and peace in consciousness were maintained. The cause of such disorder was hypothetical and still to be sought, but Dr. Collier suggested that a metabolic dyscrasia with disorder of activation of the many elements concerned was likely to be responsible rather than any local abdominal condition, intoxication, or derangement of the nervous system.

Maladjustments.

Dr. **Crichton Miller** said that the phrase " nervous women " was vague in connotation, and unhappily extensive in denotation; it included some of the most exasperating cases we were called upon to treat. He did not propose to consider cases in which an anatomical factor might be ætiological, but before passing to the strictly psychogenic to refer to three groups that for convenience might be classed as functional. These might be referred to as the physically maladjusted. The first of these groups was the amyotonic; such women were apt to suffer from every variety of visceroptosis and therefore from many manifestations of chronic abdominal pain. Therapeutically they react well to rest and massage, but tend to relapse quickly after resuming a normal life and posture. Anchoring operations were only palliative, and in so far as the real ætiology of the condition was concerned had no therapeutic value. It might be that a failure of calcium metabolism was the central pathogenic feature; if this was so, the administration of calcium and parathyroid might be useful. The second group was the vagotonic—those in whom a chronic failure of the adrenal function produced a permanent dominance of the parasympathetic over the sympathetic, resulting in inadequate thyroid activity, loss of tone, low blood pressure, and what might roughly be described as " low vitality." The improvement of an impaired adrenal function appeared to Dr. Miller the primary indication in many nervous women. The third group was the sympathicotonic. In these an increased adrenal activity stimulated the thyroid unduly, all muscular tissue was overactive, and relaxation difficult. The treatment indicated for this group appeared to him pre-eminently psychological. An overactive adrenal function depended on emotional maladjustment, and implied, to his mind, repression with a strong fear affect that was continually stimulating the " fight or flight " mechanism. There remained the cases of psychological maladjustment. The conception of any sort of pain as " all imagination," even if true, was not a particularly helpful one from a therapeutic point of view. If a pain was " all due to the imagination " it was a hallucination, and people who suffered from hallucinations were entitled to treatment as much as those who suffered from a frankly organic condition. A diseased imagination was a morbid entity requiring treatment. There was no problem on which more light had been thrown by recent advances in psychology than on this. It was only by studying the unconscious mechanisms of patients that we could apprehend at all adequately the profound significance of pain as a defence mechanism. An incidental attack of gastritis or dysmenorrhœa might offer a defence of such value to the patient that she perpetuates the pain. To describe this as " all imagination " was grossly misleading, and to infer that by an effort of will the pain could be dispelled was grossly unjust. In certain cases pain served to perpetuate a state of dependence and self-pity as against the state of independence and self-help. Pain might serve as a defence for the married woman against sexual intercourse or parturition. Dr. Miller's experience had shown that at least an appreciable percentage of cases of chronic abdominal pain in nervous women benefited by being treated on analytical lines.

Experience at Duff House.

Dr. E. I. **Spriggs** said that on looking through his cases it appeared that out of 988 women patients admitted at Duff House, Banff, and at Ruthin Castle, in the last ten years, 82 were recorded as having been nervous and having complained of abdominal pain, roughly 8 per cent.; 31 of these had undergone one or more abdominal operations. From the 82 cases he had selected 54 in whom both nervousness and pain were specially prominent, and in whom a cause for the pain was not clinically obvious; and it was upon a review of these 54 cases that he proposed to found his remarks. His conclusion was that, even in very nervous, neurotic, or neurasthenic women, if the complaint of pain was definite, consistent, and persistent, and if, after watching the patient, he believed in the pain, then there was cause for it which sooner or later is found. A diagnosis of neurasthenia as an explanation of pain was generally wrong and always dangerous. Nervousness, of course, might be and often was a result of pain. Another diagnosis, almost as likely to prove wrong, was that of auto-intoxication, since it did not go back far enough. In a large proportion of cases named auto-intoxication, a definite mechanical or inflammatory cause was found. In no less than 32 out of these 54 patients, many of whom had been regarded as neurasthenic for years, some definite condition was found sooner or later to explain the pain. The series did not include patients with visceroptosis and constipation. In six cases adhesions were definitely present in the abdomen. Massage sometimes helped these patients, and also mild aperients with oil enemas. They were difficult to improve by operation. In a number of cases there was general loss of tone, constipation, sometimes with resulting colitis and visceroptosis, of varying degree. Dr. Spriggs did not think that the low position of viscera was the cause of the constipation, &c., but that both were attributable to the poor nervous and muscular tone; we should not, therefore, expect an artificial fixation to cure the condition; and, in his experience, it did not. In the first place these operations were frequently ineffective. That the pain, nervousness, and auto-intoxication were commonly due rather to the lack of function or irregular function of the bowel than to its dropped position was shown in two ways. Firstly, by the result of treatment. It was remarkable how much could be done for these sufferers if time enough was given. The first step in the cure was the elimination, so far as possible, of the suspicion of more serious causes of pain; this alone gives the patient help and freedom from anxiety. Then came rest, fresh air, an anti-constipation diet, the inculcation of a proper habit, gastric or intestinal lavage, as the case may be, massage, abdominal exercises, sometimes the faradic current, suitable medicine, but not chemical aperients, and in due course increasing outdoor exercise. The first step towards recovery was the relief of constipation without drugs, other than paraffin. The answer to the contention that many people are not able to give the time or bear the expense of investigation or such prolonged treatment was that other and ineffective methods cost in the end more. Patients continually spent more time and money on visits to foreign resorts, voyages, special treatments, and operations of various kinds than it would take for them to be treated by their medical advisers at home or in a hospital continuously, perhaps monotonously, but effectively. In those rare cases of constipation and visceroptosis who did not yield to treatment, the bowel having lost its power of recovery, Dr. Spriggs considered the excision of the inactive part of the large intestine. Of two such patients in this series, one was found to have the muscle of the ascending colon largely replaced by fibrous tissues; she received much benefit from removal of the ascending and most of the transverse colon. The other patient, who was the subject of great visceroptosis and a constipation which proved intractable, unfortunately died from pulmonary embolism after colectomy. Even in the group of cases, of which there were five examples in this series, of women whose nervous and physical state was the direct result of psychical over-strain, it was remarkable how much good could be done by rest and treatment of physical disorders of the abdominal viscera. In conclusion, he suggested that no patient should be branded as primarily psychopathic or mental until physical causes of ill-health had been eliminated. If some definite disease not curable by medical means were found, the surgeon's help should be obtained at once, as a continuance of pain which could not be otherwise relieved added to the neurosis. It was wrong, however, to operate first and investigate after, since ineffective operations made these people worse. He held strongly that operation should not be advised for constipation and visceroptosis, unless the result of adequate and prolonged treatment had shown that the bowel was not capable of passing on its contents in a reasonably normal time.

A Physical Camouflage.

Dr. **MILLAIS CULPIN** said that from the point of view of the psycho-pathologist there were two dynamic factors in psycho-neurotic symptoms: (1) those arising through bodily changes induced by emotion, and (2) those having an end in view. Dr. Izod Bennett had done experiments in which he had tested the gastric and other secretions after inducing a state of fear under hypnosis, and had shown that the secretions were profoundly altered. It must be remembered that the nervous woman was suffering from a continued unpleasing emotion; we must not overlook the effect of a continued emotional state in producing secretory changes. Motor and secretory disturbances induced by a continued state of anxiety formed one factor in the production of chronic abdominal pain. More important still was the relation of visceroptosis to the anxiety state. Attention had recently been called by Dr. Hector Cameron to the "stance" of certain nervous children—drooping shoulders, sunken chest, lordosis, protuberant abdomen. This stance was familiar also in the nervous adult, and Dr. Culpin suggested that when uncorrected it led to visceroptosis. The second group comprised those patients in whom symptoms had an end in view. A common one was that of obtaining sympathy. Attention was always paid to physical pain by friends, whereas nervous or mental symptoms were not received sympathetically. Since patients with such symptoms had little prospect of help or understanding they were forced to take refuge in the physical symptoms which their own emotions provided. Even if obsessions were not cured the symptoms could with advantage be pushed back to the plane where they belonged, and the patient removed from the category of the chronic abdomen. There was present in most psycho-neurotics a strong tendency to hide their symptoms under a physical camouflage. Anxiety might not be present to the consciousness. Dr. Culpin quoted a patient with mucous colitis, which was emotionally determined by complicated factors. During treatment on analytical lines she said, "I used to think it was a physical disease; looking back I see it was only an excuse." Dr. Culpin pointed out also the importance of the absence of psycho-neurotic symptoms in regard to diagnosis. He had twice recommended exploratory operations in women sent to him for treatment of "neurotic" abdominal pain when he was satisfied of the absence of psycho-neurotic symptoms; in both an organic lesion was found.

He summed up with the following two propositions: (1) A continued emotional state induces physio-pathological changes in the abdominal viscera. These involve secretion, mobility, and position. It is to such changes that the word neurosis may perhaps be properly applied. (2) The symptoms first produced may be used purposefully by the psycho-neurotic patient. The purposes are of infinite variety. The one against which we as clinicians ought to be on guard is the concealment of anxiety or obsessional symptoms which it is our duty to elucidate.

Dr. J. A. **HADFIELD** said that his experience was limited to hysterical cases—namely, those in whom nothing organic can be found or which are declared to be cured after treatment by physicians and surgeons. Three facts had been generally recognised by medical men in reference to hysterical pains. First, that they had no adequate physical basis. Here a distinction should be made between an organic *origin* and an organic *basis* of hysterical disorders. Most hysterical pain could be traced back to an organic origin, such as inflammatory conditions. But such pains did not necessarily have an organic basis, since the original sensation of pain could, like any sensation, be reproduced as an image. Secondly, the significance of sexual desires had long been recognised in the very name hysteria. Thirdly, long before the Freudian psychology it was recognised that hysteria was frequently the result of the suppression of sex desires. This was expressed in the advice of many physicians to hysterical girls, "All you need is to get married." This was bad advice, for in fact more hysterias were precipitated than cured by marriage. But it nevertheless signified that physicians recognised the significance of sex suppression. What, until the Freudian psychology, we had not realised was that the sex desires which lay behind the hysteria might be quite unrecognised by the patient herself. Behind every hysterical pain there were two factors: First, there was usually an organic origin to the pain; secondly, there was a motive. Illustrations of such motives were a craving for sympathy, jealousy, masochism, and sex traumata. Hysterical pains were of the nature of "gadgets"—i.e., instruments that are employed for a purpose different from that for which they were originally intended. The patient used the hysterical pain for her own ends, whether to obtain attention or sympathy, or to enable her to tyrannise over the household.

SECTION OF ORTHOPÆDICS.

MYOSITIS OSSIFICANS TRAUMATICA.

A MEETING of this section was held on Dec. 4th at 1, Wimpole-street, W., Mr. R. C. **ELMSLIE** in the chair. Cases and specimens were shown previous to the discussion, which was also illustrated with slides.

Exhibition of Cases.

Mr. A. H. **TODD** showed radiograms of a patient's right elbow, injured in a laundry hydro-extractor, with resulting dislocation of the ulna, tearing apart of ulna and radius, and comminuted fracture of the head of the radius. After some weeks' rest in a rectangular splint, massage and movement were applied; pronation and supination were then entirely lost. Plaster fixation was thereupon applied for five months; two months later radio-ulnar arthroplasty was performed and a complete bony bridge was found; the remains of the orbicular ligament had been ossified, and there was a plaque in the anterior part of the capsule of the elbow-joint. The radiograms showed the gradual increase in ossification, followed by its cessation and sharp delimitation.

Mr. W. E. **TANNER** showed a bony plate removed from a patient who had had a hydatid cyst excised from the under surface of the liver through a right lateral incision. The wound had discharged for three years and then healed. Later the patient began to have pain after meals; a laparotomy above the umbilicus revealed no sign of hydatid disease, but a hard plaque was felt beneath the scar, and the patient was readmitted to hospital with epigastric pain. The epigastric bony scar plate was found lying in the sheath of the rectus and excised. The peritoneum was excised and no adhesions found, but there was a gastric ulcer high up on the lesser curvature of the stomach. Partial gastrectomy was performed and the patient was discharged. The bony plate measured four by one and a half inches; the anterior surface was smooth, but on the posterior surface was a boss of bone to which the rectus was attached.

Mr. K. J. **ACTON DAVIS** showed a case of bilateral myositis ossificans in an amateur footballer, aged 19, who received a kick on the outer side of the left thigh in the lower third, and was treated with massage until arrival at hospital six weeks after with a bony swelling at the site of the kick. X ray showed myositis ossificans in vastus externus. The patient had rest for some time, and then played football without any disability. A year after the first kick he received another on the right thigh; there was effusion into the joint and a very large hæmatoma on the anterior aspect of the middle of the thigh, with ecchymosis extending along the line of the vessels on the inner side. A small tear was felt in the fibres of the quadriceps in front. The patient now has definite hardening on the outer side of the thigh, which feels bony. Nothing is yet shown by X rays.

Mr. W. B. **FOLEY** showed a case of myositis associated with new bone formation in a patient who had received a bomb wound in the right upper arm and was operated upon shortly afterwards, a retained piece of metal being removed. There was no history of the use of a tourniquet. Three days later the whole of the arm became acutely painful and swollen. The swelling presented the features of a diffuse acute inflammation of the muscles, but did not proceed to suppuration. Similar attacks occurred many times afterwards. Six months after the wound was received new bone formation was observed in front of the humerus, limiting movements at the elbow-joint. This bone, removed by operation, was stated to have measured 5¾ inches in length. When seen by Mr. Foley ten months after receipt of the wound the patient was admitted to hospital for recurrent inflammatory attacks. Later in the year an X ray showed a recurrence of bone formation in front of the humerus. A Wassermann reaction was strongly positive, and an intensive course of N.A.B. was given. The limitation of movement became prominent again, and in August, two years after removal of the first bony mass, the second mass was removed and found to be definitely submuscular. A specimen of the muscle showed a fibrotic condition, with calcareous deposits. The range of movement was much improved by the second operation.

Introductory Paper.

Sir **GEORGE MAKINS** said that he would throw no new light on the condition of myositis ossificans traumatica, but would make a few dogmatic statements as to what was included under the title of the subject. The appropriateness of the name was frequently questioned; it was, in fact, an obvious misnomer. The condition was not one of inflammation, being rather an example of the process of repair. Muscle played only a passive part in it. Traumatic osteoma, myosteoma, and other names were used for these tumours, which in no respect resembled osteomata. An osteoma did not become absorbed again; some hard osteomata might eventually slough or necrose, but their spontaneous disappearance was unknown. But these wandering masses of callus within muscle were not comparable to a tumour of bone.

Various Forms of the Condition.—The "occupational" forms of the condition should not be included in the class of tumours following injuries to muscle; they depended on the awakening or renewal of the original process of the formation of bone. These bones, such as rider's bone, were usually found in the origin of a muscle. They might extend widely into the muscle, but as a rule were compact, very loose, and cancellous, generally—and in the brachialis anticus nearly always—in the form of pointed spikes. Thus they were not the same as the masses of bone found, for instance, after injury in front of the thigh. Then there was the metaplastic form, found in tabes, of large masses of bone following trauma. The injection of salvarsan into muscle might produce this form. Again, there was the question of excessive callus production after fractures; persons who showed this exuberant callus formation might have the same idiosyncrasy as those who developed ossification within muscle.

If the term was to remain in use, he suggested that myositis ossificans traumatica be limited to cases in which three essential factors were present—broken periosteum allowing the escape of bone cells, hæmorrhage, and a certain amount of injury to muscle. In the tearing off of periosteum there was hæmorrhage from the canals, which helped the diffusion of bone cells into surrounding tissue; the blood formed a nutrient medium in which bone cells might remain vital and develop, and also determined the future architecture of the tumour. The shape of the latter was determined by the sheath of the muscle. The blood, going into the muscle as a foreign body, excited a reaction, and the muscle offered a highly vascular bed in which a tumour might develop.

Morbid Anatomy and Pathology.—The microscopic interest of the condition lay, he said, in the possibility of metaplastic formation. Was the cancellous bone derived from bone cells set free by trauma, or from cells originally undifferentiated which took on bone form and function? He thought that in the main the cause lay in cells set free from injured bone. Coming to the pathology of the condition, they were entirely ignorant of the reason for its development. In this connexion must be considered the over-production of callus after a fracture; it was said that defective fixation or infection might produce defective callus. Over-production of callus was the rule, but not to a great degree, and in spite of correct treatment myositis ossificans sometimes developed. It was said that patients who developed the condition belonged to a diathesis, but that carried the question little further. It had also been attributed to excessive calcium content in the blood, but that view remained unproved. Cohn, in his observations concerning the deposition of lime salts, held that lime salts were really conveyed by the lymphatic system—that bone supplied these salts to callus, and callus eventually gave them back to bone. In tabes there was also rarefaction of bone; this might have some connexion with myositis ossificans traumatica. The real explanation would probably be reached in the future, when more was learnt of the bodily growth governed by such endocrine glands as the pituitary. The association of two tissues of different kinds might result in the formation of bone. Dr. Drew had shown that kidney cells grown in vitro would develop indefinitely, but that if connective tissue were added the kidney cells would arrange themselves inside this tissue, and a piece o organised kidney would develop.

Diagnosis and Treatment.—Sir George Makins had nothing to say concerning diagnosis. If the condition were limited to cases of ossification within muscle, it was difficult to go wrong if X rays were employed, for these tumours did not resemble any form of sarcoma. As regards treatment, the majority of cases could be treated by rest and by doing nothing to increase the supply of blood to the part. As a rule the tumour would then disappear. Sometimes a scar was left, or operation might be necessary to increase the range of movement. Operation should be deferred for perhaps three months to see if the condition cleared up spontaneously.

Discussion.

Mr. **Elmslie** commented on the large number of situations in which the condition was found. Peri-arteritis ossificans mght occur with or apart from ossification in muscle. Ossification was sometimes brought about by attempting to move a joint too soon. Legal actions were not impossible in this connexion. Remarking on the occurrence of ossification in muscle apart from any known bone injury, he thought these might be due to partial evulsions of muscle. Ossification also sometimes occurred after sepsis, for example, beneath a scar resulting from a puncture made to let out pus from a pyæmic abscess of muscle. In considering the possibility of metaplasia the essential unity of the osteoblast and fibroblast must be remembered. There was some suggestion that bone might be formed direct from fibrous tissue without any escape of bone cells. He thought it very seldom justifiable to operate within the first three months; personally, he watched until the X rays showed no alteration for a month before resorting to operation. He believed it best only to operate for mechanical obstruction.

Mr. W. R. **Bristow** showed slides illustrating ordinary myositis ossificans of the vastus internus, where there was no question of trauma. In one case severe pain occurred and quietened down, only to recur two years later, with extreme wasting of the leg, and a mass of very tender bone. No treatment was of any effect in this case. Another case, exemplifying the length of time the condition might take to clear up, was of a supra-condylar fracture of the elbow in a child; he had kept the elbow at rest for five months, after which the condition had quietened down. He emphasised the importance of teaching concerning this treatment, which was known to members of the section, but very little known outside. He wished to know if anyone could show a case of true myositis ossificans of the brachialis anticus which had been left for some time and then operated upon *with improvement.* He had never found any benefit to the patient to result from operation; the bone merely consolidated down to exactly the same state once more.

Mr. H. A. T. **Fairbank** supported Mr. Bristow's view of the importance of instruction on the subject of treatment. He believed the average general practitioner to be poorly informed in that respect, and instanced a case of forcible bending of an elbow-joint by a practitioner, to whom he had written on the subject, only to receive from him another case which had been treated in the same way. Massage did no harm, but active movements were most useful. Almost always the mass of bone seemed at first to be separate from the main bone, joining it later, and giving the appearance of periosteal thickening. At operation he had found the periosteum complete beneath the bony mass which he had removed.

Mr. **Alan H. Todd** described a case of ossification upon the front of the femur, situated apparently in the lowermost part of the origin of the crureus. The patient was a woman of 25, who had an oval loose body lying just beneath the middle of the patella; the knee was opened and the loose body found to be attached by a slender thread, apparently not vascular, to the synovial membrane of the intercondylar space. The loose body was symmetrical and oval, composed of intermingled cartilage and bone; nothing was seen that suggested that it had originated in any injury of articular cartilage or bone. An unusual amount of stiffness of the knee following the operation, it was found that a mass of new bone had formed upon the front of the femur, probably in the origin of the crureus. The limb was completely immobilised, and subsequent X ray examinations revealed the gradual increase in amount, density, and sharpness of delimitation of bone. A year after operation a full range of movement had been restored. Mr. Todd also showed a second series of radiograms, those of a man of 43, injured in the elbow region, without fracture, in a motoring smash. The ossification that had followed mapped out with remarkable accuracy the precise attachments of the anterior and posterior ligaments of the elbow-joint, and the orbicular and other ligaments of the radio-humeral and radio-ulnar joints. Mr. Todd observed that though these ossifications following upon injury had been spoken of as "callus," it appeared to him that this term was used upon totally inadequate grounds. It seemed to him to be preferable to term these formations simply "post-traumatic ossifications." Again, why was there such an extraordinary preponderance of these ossifications in the region of the elbow? Elbow injuries were very common in growing children, but that was not enough to explain the great frequency of post-traumatic ossification in this situation, as compared with all others. It seemed to him that an anatomical peculiarity of the elbow region was probably the true explanation. The islets of cartilage cells, and sometimes of bone cells, found widely distributed through the synovial membrane and even the capsule of the elbow and radio-ulnar joints, were not confined to growing children; they were to be found, also, in adults, just as many other "rests" of embryonic tissue were to be found in persons in whom growth had long ceased. Post-traumatic ossifications, apart from gross bone injury, in adults, were probably examples of activation of rests of chondroblasts or osteoblasts.

Mr. **Tanner** supported the view that the way to ensure the disappearance of extraneous bone was to rest the part.

Sir **George Makins**, in a brief reply, characterised as rash his remark about operating after an interval of three months; his own feeling had been to let things alone.

Mr. C. **Max Page**, Dr. W. T. **Gordon Pugh**, and Mr. P. **Maynard Heath** also contributed briefly to the discussion, and Dr. C. **Lambrinudi** read a short communication from Mr. W. H. **Trethowan**.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASE.

The Working of Venereal Centres.

A meeting of this Society was held at the rooms of the Medical Society of London on Dec. 7th, Dr. F. N. **Kay Menzies** being in the chair, when Colonel L. W. **Harrison**, the incoming President, delivered his address. He said it was the proud boast of the profession that though its members lived by disease, their ideal was to abolish disease. The principle of prevention of venereal disease by treating the infected underlay the chief recommendations of the Royal Commission on Venereal Disease, and was at the foundation of the Government scheme of free treatment. The scheme had three main sections: (1) Propaganda to induce the infected to apply for treatment and continue with it until non-infected; (2) discovery of infected persons; (3) their treatment until the virus had been rendered inert. Many of those engaged in this work seemed not to have fully realised that the prime motive of their enlistment was the protection of the public health. In the remarks he had to make it was inevitable that there was some criticism of many of the V.D. centres. There was at present a tendency to restrict the outlook to the particular patient, regarding him as a focus of infection needing to be sterilised. It was beneficial periodically to take stock of the situation to see how the work could be improved and speeded up. To those commissioned to establish a centre he would suggest that the chief aims should be attractiveness of the centre, with efficiency and economy in the working of it. If amenities were very poor, this did not conduce to attendance until discharged, and it would be poor economy if the arrangements resulted in only partial treatment. The average patient with these diseases was ashamed of his condition; hence it should be possible for him to reach the centre without people outside being too much aware of his object. As soon as urgent symptoms disappeared, there were serious competitors for his leisure time outside; hence the times of attendance should not clash with these other amusements; it was not desirable to require attendance on Saturday afternoons, for instance. Larger rooms for the actual work, and smaller waiting-rooms were generally desirable; it was not good that a large number of patients should be kept waiting. Also, every centre should make provision for the intermediate treatment of gonorrhœa. Better and quicker results were obtained in female cases of gonorrhœa when the treatment ordered by the medical officer was carried out by a nurse. And, to be of value, the patient must attend the clinic frequently; hence the importance of arranging times convenient to her. Too often it was assumed that patients would gladly attend at whatever times were set, at whatever inconvenience to themselves. Sometimes it seemed to have been thought too ambitious to embark on new premises, or even to have some rooms set apart entirely for the treatment of venereal diseases. And it should be remembered that gonorrhœa was much more prevalent than syphilis, and the proportion of defaulting sufferers from it was greater. He thought a V.D. centre under the public scheme worked better under one control than when it was distributed over a number of departments; apart from other considerations, it was a more economical plan; the work was better coördinated, and the public health outlook was more likely to be fostered. The number of nurses and male attendants was, in most cases, too small, and duties had to be done by medical people which could safely be left to nurses and male attendants. A trained lady almoner was a most valuable asset in a large treatment centre.

Colonel Harrison remarked that as to the means of following up patients who ceased to attend before they were considered non-infective, it was said that follow-up letters sometimes fell into wrong hands and caused domestic trouble, but a careful consideration of the matter led him to favour the sending of such letters, followed, if no response was received, by another worded more definitely. An important factor in the work was the tracing of contacts; and this could be much aided by tactful questioning of patients as to who infected them. If the medical officer of the treatment centre would place his knowledge at the disposal of the medical officer of health, improvements could be made in propaganda and in methods of advertising. When the private practitioners of the country realised the many ways in which they could help the efforts of the public health service in securing the treatment of the greatest number of infected persons, he, the speaker, thought the necessary effort would be forthcoming, and the practitioner had many opportunities of telling his public how important it was for infected persons to be treated as early as possible and until they were no longer infective. Along this path lay the establishment of a saner attitude on the subject on the part of the general public.

Discussion.

The CHAIRMAN agreed as to the desirability of having an ideal in treatment, especially in regard to treatment of venereal disease. He himself visited 28 such clinics in London, and had often asked himself wherein they failed to attain the ideal, and why. These clinics were often overcrowded; he had seen 100 patients waiting, and this did not help continuous treatment, especially as women patients objected to long contiguity with some others. He advocated the establishment of day clinics; he thought the results would soon justify the step. Colonel Harrison's clinic at St. Thomas's Hospital dealt with 4559 new cases last year, and there were 149,682 attendances, respectively 20 per cent. and 30 per cent. for the whole of London. He thought the V.D. work of a hospital should not be delegated to a junior member; the officer responsible for this department should have a place on the hospital staff.

Dr. LEONARD MYER said the attendance at St. Paul's Hospital clinic was about 20,000; patients could attend on Sunday.

Dr. J. C. BUCKLEY spoke of the difficulty of getting doctors and trained orderlies or nurses for this work in Nottingham. In his clinic the gonorrhœa treatment was kept separate from that of syphilis. A good point about the clinics was that the patients remained under the same doctor. In his establishment there was in operation a thorough system of following up patients who grew lax in their attendance. The irreducible minimum of patients who would not continue attendance was only 12 per cent. It was insisted that attendance must continue until the patient was discharged cured; if he moved to another town, he was given a transfer to the clinic there.

Dr. F. H. LAWSON gave his experiences at the Brighton and Worthing clinics. At the former there were six clinics a week, at the latter two. There was a close and cordial working arrangement with the medical officer of health.

Reply.

Colonel HARRISON, in reply, said that at present there was too much working in watertight compartments. The medical officer of treatment centres could be of real use to the medical officer of health, and vice versa. He believed the St. Thomas's clinic would this year reach a total of 120,000 attendances. The cost per attendance at that centre was 1*s.* 5½*d.* The price of materials for female gonorrhœa subjects was considerable; it was very small for males. With regard to the conference at Copenhagen, it was a great inconvenience that the results of serum tests were reported in different terms. It was most important to have standardisation, especially in the case of merchant seamen and others who travelled over the world. In May, 1921, a resolution was passed at Copenhagen requiring that the blood tests of various countries should be compared with one another; and the first-fruits of that was a London Conference, under the ægis of the League of Nations Health Organisation, at which it was resolved that in a number of European laboratories a comparison should be made of the various methods of testing serum for syphilis. Attention was specially devoted to the sigma test, as standardisation of that would give quite smooth results.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Dec. 5th, Sir DAVID WALLACE, the President, being in the chair.

Exhibition of Clinical Cases.

Dr. MARY H. MACNICOL showed a case of multiple arthritis in an infant following ophthalmia neonatorum. Dr. J. V. PATERSON did not regard the evidence of ophthalmia neonatorum as conclusive.

Mr. DAVID LEES showed four cases of interstitial keratitis treated by intramuscular injections of bismuth. He considered the results to be more satisfactory than those obtained with arsenical salts.

Dr. W. T. RITCHIE showed a case of progressive lipodystrophy in a female, aged 24, single. The disease, which was neither hereditary nor congenital, began at the age of 11 by the face becoming thin. The thinness of the face was progressive for two years, and was subsequently stationary. The face, arms, and trunk down to the level of the iliac crests were very thin by loss of subcutaneous fat; the gluteal regions, thighs, and legs were plump owing to excess of subcutaneous fat; the muscles were healthy. There was no evidence of disturbance of function of the thyroid, pituitary, pancreas, ovaries, or suprarenals. The case was a typical example of the rare disease, first observed by Osler in 1895, and designated lipodystrophia progressiva by Simons in 1911.

Dr. R. A. **Fleming** and Dr. **James Davidson** communicated (1) a case of acute myeloblastic leukæmia. Clinical notes of the case were given with lantern slides showing mitosis on blood films and the pathological changes in the various organs. (2) A case of aplastic anæmia. Notes were given and lantern slides of the pathological changes were shown. Prof. G. L. **Gulland** and Dr. **John Orr** discussed the diagnosis and treatment of the cases.

Dr. A. **Nimmo Smith** and Dr. A. **Fergus Hewat** gave a communication on the

Complement-fixation Test in the Diagnosis of Tuberculosis,

with special reference to pulmonary tuberculosis. The principles on which the test is based were outlined and reference made to the variation in methods of technique. The technique employed in a series of 400 cases was briefly described. The results of the tests were grouped under five heads: (1) Where *B. tuberculosis* was present at the time of the test; (2) cases of clinically active tuberculosis but without bacteriological evidence; (3) cases of clinically inactive tuberculosis; (4) non-tuberculous cases where the Wassermann reaction was positive; (5) patients suffering from diseases other than tuberculosis and where the Wassermann test was negative. In "sputum positive" cases between 80 and 90 per cent. gave a positive reaction to this serological test. In some of the remaining cases the negative result might be explained by low resistance and the absence of formation of antibodies. In a few cases of definite tuberculosis the reaction remained persistently negative. No explanation of this could be offered. The conclusion drawn from the results was that in doubtful cases a positive result was of value, but a negative result could not be regarded as evidence of the absence of tuberculosis.

In opening the subsequent discussion, the **President** read a letter from Sir Robert Philip, who was unable to be present, in which he confirmed the views expressed. There subsequently spoke Dr. A. **Rutherford**, Dr. H. **Richardson**, and Prof. T. J. **Mackie**, the latter considering that the test was only of confirmatory value.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A meeting of this Society was held on Dec. 13th, Dr. **Eliot Curwen**, the President, being in the chair.

Exhibition of Cases and Specimens.

Dr. **Neville Cox** showed a case of hereditary deforming chondrodysplasia in a girl aged 13. Deformity and disability in the use of one forearm began about the age of 9, and have been increasing. Recently similar changes in the other forearm had begun to appear. There was difficulty in fully extending the elbow and in supination of the hand. The X ray showed bowing of both bones of the forearm with displacement of the upper end of the radius, and irregular bone formation and bony projections from the lower end of the shafts of both bones adjoining the epiphysis. There were also bony outgrowths on the inner side of the head of each tibia. The child was knock-kneed, and had slight lateral spinal curvature, but otherwise was in good health. None of her three brothers and sisters were affected, but the father had similar bony outgrowths on the tibiæ.

Dr. H. M. **Galt** showed microscopical slides of a section of normal vagina, normal Fallopian tube, and normal endometrium; two sections of polypus of nose; a section of polypoid growth of nostril; he also demonstrated the latest pattern of Dare's hæmoglobinometer.

Mr. D. A. **Crow** read a paper on the

Comparative Anatomy of the Nose as a Guide to its Medical and Surgical Treatment.

The development of the olfactory and respiratory portions, he said, was traced throughout the various groups of animals, commencing with fishes, whose nose is exclusively olfactory, reference then being made to the dipnoi, where for the first time the respiratory function is combined with the olfactory. In the reptilian type the two functions are still associated, the olfactory remaining in the upper compartment of the nose, and the respiratory being more definitely associated with the lower. In birds, whose olfactory sense is not unusually highly developed, the same general arrangement persists. Note was then made of the deficient olfactory sense in such species as the duck bill platypus and the cetacea, contrasting this with the very high olfactory development in creatures of nocturnal habit such as echidna, dog, and cat. The organ of Jacobson was demonstrated in the sheep, and the theory of its association with herd sense discussed. The various modifications of the respiratory part of the nose, as distinct from the olfactory, were then illustrated by diagrams of the nose of the kangaroo and walrus. The morphology of the human nose was then dealt with, and attention having been drawn to the very limited area devoted to olfaction the respiratory area was defined, emphasis being laid on the intermediate area, including the accessory sinuses, which is an area of indeterminate function, and like all residual organs, becomes vulnerable to disease, especially when an *acquired* non-functioning due to nasal obstruction is superadded to the non-functioning of congenital origin. The pathology of catarrh was briefly dealt with, and a diagram presented to indicate the sequence of pathological events which resolve themselves not into a vicious circle merely, but into a "vicious figure of 8." Emphasis was laid on the futility of operating on the nose, except as a palliative measure, after destruction of ciliated epithelium, if the expectation is to cure the patient's catarrh; for ciliated epithelium is never regenerated, and on it depends the whole question of sanitation of the nose. But whilst a protest was entered against too frequent and too extensive nasal operations in the later stage, an appeal was made for more readily removing the causes of catarrh during the first half-turn of the vicious "figure of 8," whether the cause were adenoids, septal deflection, constipation, or that main cause of catarrh, a fear of climate.

The paper concluded with reference to reflex nasal effects and a brief note on olfaction; it was discussed and criticised by the **President**, Mr. A. J. **Hutchison**, Drs. C. H. **Bryant**, L. A. **Parry**, and **Donald Hall**.

Mr. **Crow** also showed the nose of a sheep dissected. The septum had been half cut away and the remainder reflected, showing the organ of Jacobson partially dissected out. On the lateral wall was seen the large (respiratory) maxillo-turbinal (also shown in cross section) and the numerous (olfactory) ethmo-turbinals, also the naso-turbinal. A small piece of maxillary sinus mucous membrane was exposed.

Fourth Northern General Hospital, Lincoln. The fourth annual dinner of the staff was held at the White Hart Hotel, Lincoln, on Dec. 13th. There were present Lieut.-Colonel Lambert, Majors Tinley, Shipman, Watkins, Rainforth, Lowe, Captains Willoughby Smith, Alcock, Pratt, Barlow, Captain and Quartermaster Dickinson, and the Rev. C. E. Bolam, C.F. A discussion took place on the future organisation of the dinner, and in view of the small attendance this year it was decided to widen the scope of the function and to include as members all medical officers who served in the late war in the Navy, Army, and Air Force who live in Lincoln and the vicinity; together with the quartermasters and chaplains who served at the Fourth Northern General Hospital. It was decided to hold the dinner annually in the spring, and that the next dinner be held in April, 1925, when Colonel A. M. Connell, A.M.S., will preside.

Reviews and Notices of Books.

TREATMENT OF FRACTURES IN GENERAL PRACTICE.

By C. MAX PAGE, D.S.O., M.S. Lond., F.R.C.S., Senior Surgeon to Out-patients, St. Thomas's Hospital; and W. ROWLEY BRISTOW, M.B., B.S. Lond., F.R.C.S., Surgeon to the Orthopædic Department, St. Thomas's Hospital. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. With 142 figures in the text. Pp. xi.+239. 12*s.* 6*d.*

THE treatment of fractures until the late war had fallen into rather a low estate, out of which the brilliant operative treatment of Sir Arbuthnot Lane failed completely to rescue it. For the method of operation and plating was obviously inapplicable to the needs of general industrial practice, seeing that it could only be successful in a well-equipped hospital. Yet as the late Mr. Clinton Dent showed, the amount of temporary or permanent disability after such a comparatively minor injury as a Pott's fracture of the fibula is very great and has a far worse effect on a workman's earnings than many diseases, which are cured by difficult and delicate operations. For these reasons we welcome this book. In it the simplest efficient methods of treating all the fractures that are likely to be met with in general practice are described, not forgetting first-aid devices. The reader is not bewildered by being offered the choice of several methods, but generally he is told what proceeding has given the authors most satisfactory results, and he is shown how to carry it out. The diagrams, X ray pictures, and other illustrations are clear and satisfactorily illustrate the text. A very important question which is too often ignored in larger works on fractures is dealt with in this handbook. That is, how is the Scylla of the danger of permanent stiffness or atrophy from too long fixation of joints and muscles to be avoided, without falling into the fatal Charybdis of recurrent deformity or faulty or deficient union? We think that the advice given on these matters is sound. The difficult region of the elbow-joint receives special attention, and the way to avoid the awful disaster of ischæmic paralysis of the hand is plainly pointed out.

The experience gained by one of these writers in the Balkan war, and by both at the Special Hospital at Shepherd's Bush, has fully qualified them to write with authority on the subject. It is to be hoped that in the future it will occupy a much more important position in the training of students than it has done for some years past in metropolitan schools of medicine. Many a young country practitioner's reputation may be made or marred by his manner of handling a case of fractured femur in a locally important patient. Woe betide him if he does not employ X rays in its diagnosis and treatment! In default of the proper training, or in addition to it, the study of this book will not only prevent his making technical blunders and being cast in damages by a not too intelligent jury, but will ensure that his patients get the treatment best suited to their needs and circumstances.

L'HÉMATOBLASTE, TROISIÈME ELÉMENT DU SANG.

Par GEORGES HAYEM, avec avant-propos et annotations par le Dr. L. RIVET, Médecin des Hôpitaux. Paris: Les Presses Universitaires de France. 1923. Pp. 254. Fr.25.

THERE has always been an unfortunate tendency among students of the formed elements of the blood to confer upon them names indicative of their supposed place in the hæmatological genealogical tree before that place had been properly determined. "Hématoblaste" is one of these terms, coined by Prof. Hayem and by him applied to that element of the blood known in this country as the "platelet," with the purpose of indicating the originator's view that these bodies represent incompletely developed red cells. It must always stand to Prof. Hayem's credit that, while physiologists and pathologists in this and other countries were denying their existence, he was actively engaged in the study of the platelets; at the same time it must be admitted that his evidence as to their alleged relationship to the red cells, on the strength of which he has bestowed upon them the Greek polysyllable, is of the scantiest: it mainly depends on the observation, first made by himself, that in states of regeneration after blood loss or destruction the rise of the red-cell count is preceded by an initial increase in the platelets in the circulating blood. Interesting as it is, all that this observation really indicates is a probability that both platelets and red cells derive from a common tissue system. The most interesting portions of the book are devoted to the comparative anatomy of the platelets, a field into which Prof. Hayem was among the first to enter and which is still largely unexplored.

Dr. L. Rivet provides an introduction in which he gives histories of the growth of knowledge on the subject of the platelets, and also of Prof. Hayem, both of considerable interest. He has also edited a series of annotations, constituting Part II. of the book, in which, in the section on the therapeusis of the platelets, he accomplishes a notable feat in describing the procedure of blood transfusion without making any reference to the blood groups. English readers should note that when "anémie pernicieuse" is spoken of that condition of the blood known in this country as "aplastic" anæmia is apparently indicated.

There is still an opening for an up-to-date book on the blood platelets.

THE INFANT AND YOUNG CHILD.

By JOHN LOVETT MORSE, A.M., M.D.; EDWIN T. WYMAN, M.D.; and LEWIS WEBB HILL, M.D. London and Philadelphia: W. B. Saunders Company. 1923. Pp. 271. 8*s.* 6*d.*

IN this book, which is addressed to mothers, the writers have set themselves the task of anticipating and answering the questions which mothers are in the habit of asking about the many details of infant care. There are five main sections in the book, dealing respectively with antenatal preparations, feeding, growth and development, care and training, and lastly, diseases, emergencies, and medicines. The final section is designedly short and somewhat sketchy, as it is not intended in any way to take the place of a physician when the child is ill. The range of topics discussed is wide, since the book deals with the treatment of children up to the age of 6 years, but the authors have observed throughout an excellent perspective, stress being laid rather on the principles of treatment than on more or less trivial details. We do not, however, find ourselves altogether in agreement with them with regard to some of their teaching. The list of contra-indications to suckling is over-long, and includes a warning that really delicate and feeble women should not nurse their babies "because, as a rule, the milk is poor, and the strain of nursing is too much for them." It is also considered inadvisable for women who have some chronic disease—other than syphilis—to suckle their babies; while even clinically inactive pulmonary tuberculosis is a contra-indication unless the mother has been cured for a long time and is comparatively well. We fancy that most of the pædiatrists in this country would qualify all these statements. The section on artificial feeding is good, but it is unfortunate that no mention is made of the principle of taking the weight of a baby rather than—or at any rate together with—its age as a guide in regulating the amount of food needed. In the chapter on mixed feeding it is said that where the supply of breast-milk is almost sufficient, the baby may be given the artificial food at one or two feedings in place of the breast—advice which we look upon as entirely wrong in principle. In the main, however, the teaching given is sound and helpful, and the book should be useful to the section of the public to whom it is addressed.

How our Bodies are Made.

By R. M. Wilson, M.B., Ch.B. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 246. 5*s.*

Conversations on the meaning of symptoms or the reasons for disorders between patients and doctors often end in confusion—each party feeling embarrassed or contemptuous in the attempt to make himself understood in a foreign tongue. This is largely because the doctor thinks in technical terms which are unintelligible even when translated, since the foundations of the lay conception of the structure and functions of the human body have been neither well nor truly laid. There is no common basis on which to build, and those who attempt to find one are apt to be discouraged by the preliminary amount of spade-work required. Often it is not until the clamour of questions arises from a younger generation, questions which can neither be hushed nor answered, that adults become aware how limited is their knowledge of vital processes. If is for these reasons that this little book, which is intended for very young people, will be read greedily and then be studied seriously, not only by children but by parents, to their mutual benefit. Not only has it a wealth of breezy martial imagery which cannot fail to stimulate the desire for more knowledge and for active endeavour towards a sane mind in a fit body, but its valuable negative qualities, absence of patronage and sentimentality, deserve praise. It would be difficult to give an adequate idea of the ingenuity of the analogies suggested and in many cases pictured. The chapter headings are admirably chosen. They include The Hardest Worker in the World, The Soldiers at the Gate, How People are Born, The Red Submarines and the White, When You Cut Your Finger, The Hole in the Wall, Hitting and Hitting Back—to quote only a few. Throughout the book aeroplanes, ships, engines, telephones, and scouts act as prototypes, but never is an analogy strained to explain the facts nor the facts distorted to complete an analogy. The illustrations, with the sole exception of the distorted figure on p. 145, are most suggestive. For example, a diagram of the action of a trap-door makes that of the heart's valves obvious to anyone. The movements of blood corpuscles are much more entrancing when pictured as the activities of red submarines, taking a cargo of fresh air to the lung and removing a cargo of used air, and it becomes of great interest to learn where these submarines are built and where broken up after a short but busy life. It is a happy coincidence that this book should have been published at the same Christmas season as Kipling's appeal to Scouts and Guides: "Be fit—be fit! In mind and body be fit!" Kipling has pointed out the ideal, and Dr. Wilson shows boys and girls and parents how to achieve it.

Applied Pathology in Diseases of the Nose, Throat, and Ear.

By Joseph C. Beck, M.D., F.A.C.S., Chief of Staff, Otolaryngology, North Chicago Hospital. London: Henry Kimpton. 1923. Pp. 280. 37*s.* 6*d.*

Dr. Joseph Beck says, in his preface to this book, that he has long felt the need for a text-book limited to the pathology of nose, throat, and ear diseases; he further states that he has decided to make this work one on applied pathology, and that it was his desire to limit it almost exclusively to his own personal experiences. The effect of the first design is that the clinical aspect of the various affections, and the discussion of their treatment, form by far the larger part of the book, and that the pathology has been relegated to a very secondary place. From the second part of the author's plan it results that the pathological descriptions are extremely incomplete, and that many interesting conditions are completely omitted. Thus, although a place is given to diseases of the œsophagus, the very interesting condition of dilatation without stricture escapes all mention; the pathology, also, of the commoner affections, such as cancer of the larynx, is very inadequately described, and sarcoma of this region is not mentioned at all. Syphilitic labyrinthitis receives a scanty mention from its clinical aspect, but no allusion to its pathology, and even the pathology of nasal polypus is but briefly described. In fact, the book is not a systematic work on pathology, but resolves itself into a sketchy general description of some of the diseases of the nose, throat, and ear. It is very well printed, and some of the illustrations, which are numerous, are excellent.

Digitalis Therapy.

Die Digitalis und ihre therapeutische Anwendung. Authorised German translation (by Prof. Dr. P. Neukirch) of a Monograph written by various Dutch authors. Berlin: Julius Springer. 1923. Pp. 119. $1.35.

The compliment we pay to this publication is a high one: that we hope it will be translated into English, for it should be read widely. It is a well-balanced critical review of a subject which has become difficult to understand, partly owing to chemical intricacy, partly owing to a plethora of writing, but still more largely by an incoördination of terminology, itself based on international jealousy and business competition. In 1920 the Dutch Government founded an imperial institute for pharmacological and therapeutical research to inquire into suitable drugs and secret remedies. Oil of chenopodium, salvarsan, and quinine and quinidine have been reviewed in the way that digitalis is now treated. William Withering receives full credit for his pioneer work; his writings are quoted at some length, always with approval. The writers consider his remarks so concise and definite that no summary of them is necessary, and compare his monograph with the later writings about digitalis. Modern literature on the subject would fill volumes, but would contain little of practical value that is not laid down in the few pages of Withering's account. After this acknowledgment digitalis is considered from all sides—chemical, pharmaceutical, pharmacological and therapeutical—and strophanthus is included in the review. To trace the history and to assign a worth to the numerous preparations and supposed constituents of a drug like digitalis is a big task, but it is a task here well done; the subject is treated in a manner that is full yet concise, and the text is comprehensive though eminently readable. The publication is a model of what a monograph should be, and is a credit to the Rijks-Instituut.

Medical Climatology of England and Wales.

By Edgar Hawkins, M.A. Oxf., M.D. Edin. London: H. K. Lewis and Co., Ltd. 1923. With 149 Charts (144 in colours). Pp. xiv. + 302. 25*s.*

Medical practitioners will find this creditable and handy volume of much service when dealing with medical climatic problems. The information has been culled from the standard volumes on meteorology and geology, as well as from works on spas, health resorts, pleasure resorts, and travel, and the author has rendered the subject-matter easily serviceable by free use of excellent coloured charts. The various meteorological factors for each district or place are expressed in percentages either above or below the normals for the whole of England and Wales. In this way we may compare for different places the annual mean values of temperature, sunshine, rainfall, daily range of temperature, cloud, relative humidity, relative frequency of the three most prevalent winds, the average number of days of snow, hail, thunderstorm, fog, gale, and rain. Although details of many places are given, cost of printing has been responsible for omissions. While the work fulfils the functions of a general guide, a practitioner should have some personal acquaintance with a place before expecting to obtain any aid from climate. No claim can be made that climate alone will cure disease. Nevertheless, climate may make life much easier and may also act as an efficient assistant to nature and to drugs in very many conditions of ill-health. On the other hand, an unsuitable place may do much to retard recovery. Attention may well be given to the effects of the place on the patient's mind, and social conditions cannot be left out of consideration.

Climates are divided into two main classes, bracing and sedative; these terms to be construed as relative to the place in which a patient is residing. Brighton may be expected to be sedative to an inhabitant of Margate. Thus a place within a few miles may afford the desired change. The author is to be congratulated on producing a small volume, suitable for ready reference and containing details taken from many well-known fields; nevertheless, many facts in the book will be recognised as old friends. What one misses is the freshness of new facts—that is, some reference to the researches of the past 15 or 20 years in England itself; full attention should have been given at least to the work of Dr. Leonard Hill, F.R.S., on the scientific side, and of Sir Henry Gauvain on the clinical side. If we are to advance, new facts must be emphasised even in our small text-books.

The book is well arranged, and, for the practitioner, is probably the best of its kind now available. One or two maps might with advantage be included in a future edition.

THE OLD DOCTOR.

By FRANK G. LAYTON, M.R.C.S., L.R.C.P. Birmingham: Cornish Brothers, Ltd. 1923. Pp. 170. 4*s.* 6*d.*

Dr. Layton has already published a number of plays and books. "The Old Doctor" is a study of medical life in a Midland town before the days of the National Insurance Act. It is written by a man of insight and feeling, keenly alive to the hardships of the general practitioner's life in the back streets of an industrial town, where calls were many but fees often remained unpaid. These were the times of the penny clubs, when the sixpenny doctor—advice and a bottle—flourished; ten years is a long time in the recent history of medicine, and most of the "old doctor's" idealistic schemes have since been realised. The author has a Dickensian touch; his characters are rather types than human beings—the young medical man fresh from the university, the bluff, kind-hearted old practitioner, the unscrupulous cash-down "consultant," the High Church parson, and the Labour leader—and certain inevitably sordid pictures are relieved by the grace of humour.

JOURNALS.

QUARTERLY JOURNAL OF EXPERIMENTAL PHYSIOLOGY. Vol. XIII. Nos. 3 and 4. Pp. 199–404. London: Charles Griffin and Co., Ltd. November, 1923. 20*s.*—The General Effects of Exposure to Radium on Metabolism and Tumour Growth in the Rat and the Special Effects on Testis and Pituitary, by J. C. Mottram and W. Cramer. This is a contribution to the study of the effects of small doses of radium. When small doses are applied over long periods to young rats these animals put on weight more rapidly than the controls and become very obese. The pituitary body shows changes in all three parts of the gland, and on the testis the primary effect is the atrophy of the seminiferous tubules, the resulting shrinkage of these tubules allowing the interstitial cells to hypertrophy. Comparison with the effects of castration shows that the elimination of the functional activity of the seminal epithelium does not lead to obesity. It only produces certain definite changes in the anterior part of the pituitary body. The obesity is, in this condition, at any rate, the direct or indirect result of the hypertrophy of the interstitial cells, which also produces changes in the intermediate and posterior portions of the pituitary. The observations show that the two component tissues of the testis, the spermatogenic tissue and the interstitial tissue, have two distinct and independent effects on the organism, and of these two effects that of the interstitial cells is the more profound. Even in the absence of the spermatogenic tissue the interstitial cells furnish an internal secretion which produces definite changes in the intermediate and nervous portions of the pituitary, changes which, through the action of this gland and possibly also through the action of some other endocrine organs, affect the metabolism. These effects on endocrine organs and metabolism represent probably the actual basis of the general changes stated by Steinach to occur after implantation of trabecular tissue, and when induced in a senile organism, described vaguely as rejuvenescence. Resection of the vasa deferentia produces no very obvious changes in either testis or pituitary, and does not produce obesity. Rats which have been rendered obese by exposure to radium are more resistant to the growth of transplantable tumours. —Functions of the Pituitary and Thyroid Glands, by Norman M. Dott. This research includes the technique of experimental surgery of these glands and a summary of the author's results. Important both to the experimental physiologist and to the surgeon whose work lies in the domain of cerebral surgery is the very full and copiously illustrated exposition of the technique for experimental operations, more especially on the pituitary gland. The experiments were made on dogs and cats. The experimental pituitary derangements are considered and discussed, and the opinions founded thereon are to be regarded as provisional. The general conclusion arrived at is that the anterior lobe exerts a powerful influence on the cell activities of the body tissues generally and that it exerts a specific and vital influence on tissues of an embryonic type, as represented by the epiphyseal cartilages—X ray photographs are given—and germinal epithelium. The pars nervosa is of less physiological significance, for its complete extirpation causes no physiological disturbance. A lesion of the thyroid, being a simple homogeneous gland, is more easy of interpretation. Total extirpation of the thyroid is compatible with indefinite survival. Complete removal—athyroidism—was followed by subnormal temperature, adiposity, and lethargy—signs which were interpreted as due to depression of the metabolic rate. A single injection of thyroid extract caused a rise of temperature, beginning after 2–8 hours and lasting for 20 hours. Injection of the anterior lobe pituitary extract in the thyroidless animal caused similar results as regards temperature and liveliness. Histological examination showed that there was no degeneration in the epiphyseal cartilages as in pituitary deficiency, the bone and cartilage merely remaining in infantile condition. Thyroid injection restores epiphyseal growth to normal as determined by accurate X ray measurements. In hyperthyroidism the generative organs share the general acceleration of maturation without deviation from the normal beyond their more rapid development. Practically no changes were observed in the other endocrine glands, apart from those in the pituitary body, and, notably, the parathyroids were quite normal after thyroidectomy. Thyroid feeding produced no obvious changes in the thyroid. Athyroidism in young animals was characterised by a state of persistent infantilism. In contrast to the thyroid, which appears to influence the rate of tissue processes only, the pituitary body exerts, in addition, a special influence on the vitality of the embryonic types of tissue.—R. K. S. Lim, Alister R. Matheson, and W. Schlapp contribute papers on "An Improved Method for Investigating the Secretory Function of the Stomach and Duodenum in the Human Subject" and "Observations on the Human Gastro-Duodenal Secretions, with Special Reference to the Action of Histamine." Lim and Schlapp collaborate in a paper "On the Effect of Histamine, Gastrin, and Secretin on the Gastro-duodenal Secretions in Animals." The "improved method" is described and its technique figured and explained; it consists essentially in applying continuous suction to these organs simultaneously by two separate tubes.—The other papers on Syneresis, or Contraction of Blood Clots, by J. W. Pickering and J. A. Hewitt; Effect of Adrenaline on Left Auricular

Pressure, by R. J. S. McDowall; Inhibition of Hæmolysis and Absorption of Adrenaline by Kaolin, by Eric Ponder; Reflex Times in the South African Clawed Frog, by W. A. Jolly; and the Influence of Hypophysectomy on the Rate of Carbon Dioxide Production in Frogs, by Frank R. Winton and Lancelot T. Hogben.

THE INDIAN JOURNAL OF MEDICAL RESEARCH for October contains 33 articles, some of which are of considerable interest. In some instances there are several contributions by the same author, or group of authors.—R. McCarrison has one of his familiar articles on the pathogenesis of deficiency disease.—J. F. Caius and K. S. Mhaskar contribute a series of five articles on the composition of anthelmintics and their relative therapeutic values. These papers throw light on the complex chemical compositions of many drugs which have been tested.—U. N. Brahmachari has a series of three articles on the chemotherapy of antimony compounds in kala-azar, while H. E. Shortt and R. T. Sen contribute a short article on the action of urea stibamine in this disease, a substance which they found more effective than antimony tartrate.—A. C. Vardon has produced desiccated nutrient media for use in small laboratories; W. F. Harvey and K. R. K. Iyengar continue their work on bacterial vaccines. F. W. Cragg has studied the bionomics of the bed bug, and P. J. Barraud contributes two more parts upon the revision of the culicine mosquitoes in India, and describes two new species from Assam.—C. A. Gill has two papers on malaria.—E. Muir has an illuminating article on the treatment of leprosy considered in the light of the nature of its spread throughout the body.—There is another record of the recovery of *Herpetomonas donovani* from the urine in a case of kala-azar, by H. E. Shortt, C. S. Swaminath, and R. T. Sen.

Reports and Analytical Records.

ALUNOZAL.

(DICK, COATES AND CO., 41, GREAT TOWER-STREET, LONDON, E.C. 3.)

IN addition to urazine, a product of the Laboratoire des Produits "Usines du Rhône," to which we called attention in our issue of Nov. 17th, we have received a sample of alunozal, a basic salicylate of aluminium which has been used with some success as an intestinal antiseptic in France, particularly in cases of infantile and tuberculous diarrhœa and in enteritis. The preparation is supplied in compressed tablets and in granular effervescent form containing 25 per cent. of the substance, and it is claimed to be non-irritating. Taken in a little water it is tasteless, and the dose of the granular form is ½ to 1 spoonful for an infant, 1 to 4 spoonfuls for a child of older years, and 3 to 6 spoonfuls for an adult. The preparation should not be taken in connexion with alkaline substances such as bicarbonate of soda, Vichy water, and so forth.

"SOLOID" ALUMINIUM SULPHIDE.

(BURROUGHS, WELLCOME AND CO., SNOW HILL-BUILDINGS, LONDON, E.C. 1.)

The preparation of small quantities of sulphuretted hydrogen for use in water analysis is cumbersome by the ordinary methods. Messrs. Burroughs, Wellcome and Co. have produced a "soloid" aluminium sulphide (0·1 g.) by which an H_2S solution may be quickly prepared by placing in 10 c.cm. of water one "soloid" and allowing it to remain for two or three minutes. By this means the water becomes saturated with H_2S, and a small quantity of sulphuretted solution for water analysis or any other purpose can be conveniently and quickly prepared. "Soloid" aluminium sulphide is sold in packages of 25, each "soloid" containing 0·1 g.

BISMUTHYL, BI-QUINYL, AND INJECTABLE URENILE.

(PRODUITS CHIMIQUES ET PHARMACEUTIQUES "MEURICE," 68, RUE BERKENDAEL, BRUSSELS. LONDON AGENTS: MESSRS. L. H. GORRIS, 49, QUEEN VICTORIA-STREET, LONDON, E.C. 4.)

The use of bismuth compounds for the treatment of syphilis by intramuscular injections has stimulated the Produits Chimiques et Pharmaceutiques, "Meurice" to place upon the market two preparations, bismuthyl, precipitated bismuth (97 per cent. of pure metal), and bi-quinyl, double iodide of quinine and bismuth (5 per cent. of bismuth), for which satisfactory results are claimed by French and Belgian doctors. Both the rapid disappearance of spirochætes as well as complete cicatrisation of any lesions present have followed the use of bismuthyl, the dosage of which is 2 c.cm. aqueous suspension (containing 0·2 of bismuth) for intramuscular injection. This does not give pain and is free from toxic sequels. One dose, which is contained in one ampoule, is administered every five days until 2·5–3 g. of bismuth have been injected—that is to say, 12 to 15 ampoules. The treatment is given three times at monthly intervals, but is stopped after the third treatment if the Bordet-Wassermann reaction remains negative.

Bi-quinyl is a double iodide of quinine and bismuth, the metal being in the relation of 50 per cent. It has been found useful when administered between courses of arsenobenzol, and, like bismuthyl, its administration has been shown to be painless. Patients who are resistant to the action of arsenobenzol have obtained benefit from intramuscular injections. The injection dose for adults is 0·3 g. of the salt, the equivalent of each ampoule, which contains 3 c.cm. of active salt in sterile oil solution. The injection is made every three days until 15 or 20 injections have been given and the course is repeated after a rest of ten days. A smaller dose can be administered to children. Bismuthyl and bi-quinyl are both put up in boxes containing 12 ampoules.

Another preparation of this firm is injectable urenile, introduced in 1921, which is a chemically pure solution of hexamethylene-tetramine. The action depends upon the liberation of formaldehyde by the decomposition of hexamine. In septicæmic infections favourable results have been reported, and even apparently hopeless cases of encephalitis lethargica have responded to its use. In diabetic acidosis an injection of 2, 4, or 6 g. has been found valuable. Administration is by intramuscular injection into the buttock, which with proper technique does not cause pain. Intravenous injections are recommended when four or more grammes of solution are to be injected. The initial dose, as a rule, is 1 g. (0·5 g. for a child) followed by 2 g., 4 g., or more as required. The preparation is packed in boxes of 12 ampoules, each containing either 1 or 2 g.

SALICIN.

(THE ST. AMAND MANUFACTURING CO., LTD., CARNWATH-ROAD, FULHAM, S.W. 6.)

The use in rheumatism of salicin was referred to in the columns of THE LANCET by Dr. T. Maclagan as early as 1876, and since that time it has been increasingly used not only in rheumatism, but in the treatment of certain skin affections and in aborting influenza. Salicin is a glucoside of salicylic alcohol, obtained from the bark of certain species of willow and poplar. It is a British Pharmacopœial preparation, and a little book which is issued by the St. Amand Manufacturing Company to medical men summarises succinctly the stages of its application to various affections, drawing special attention to the use of salicin in influenza. A sample of the drug which we have received is made up in compressed tablets of 5 gr. each, and as they will be sent free to any medical man who applies for them an opportunity is given for testing a drug that has given gratifying results.

THE LANCET.

LONDON: SATURDAY, DECEMBER 22, 1923.

CANCER RESEARCH.

THE scientific reports of the Imperial Cancer Research Fund are issued, not annually, but at irregular intervals, and so, though the Fund has been in existence for 21 years, only seven reports have preceded the one just published. The wisdom of this policy of restraint is apparent to anyone whose acquaintance with medical science is anything but the most superficial. Though the story of cancer research in this country is one of endeavour and achievement, it contains in addition many dark chapters of frustated hopes, and the lot of the workers in this field would be hard indeed were they required to publish according to a time-table. As it is, the custom of the Fund has been to issue from time to time in collected form such papers as appear to be of more than passing interest. These reports represent, as it were, chapters in the history of the Fund; they contain material which is published without haste, and they are recognised by serious students as permanent contributions to our knowledge of the subject. Moreover, while the lay press is only too eager to cater for the appetite of a sensation-loving public, the value to medical science as a whole of an organisation which steadfastly refuses to pretend that the secrets of biology are at the service of the long purse and the strident voice is incalculable.

The present report is made up of ten papers, some of which have already appeared in various journals, while others are now published for the first time. Dr. J. A. MURRAY, the director, divides them into two groups, according to whether they deal with the behaviour and character of the cell already cancerous, or with the changes the cells undergo in becoming cancerous; and we do not suppose that anyone will be found to quarrel with this grouping. But looked at from another point of view, the report is evidence of the extraordinarily wide field embraced by the work of the Fund, for the separate papers might as justly be grouped under the headings, Physiology, Biochemistry, Experimental Biology, Descriptive Pathology, and Experimental Pathology; while the clinical side is represented by the inclusion of Dr. A. SCOTT's monograph on Paraffin Dermatoses and Cancer in the Operatives of the Scottish Shale Oil Industry, one of the most valuable contributions to the clinical study of malignant disease with which we are acquainted, and now published in full for the first time. A more or less detailed abstract of some of the papers in the report appears in another part of this issue, but certain generalisations which emerge from its study may usefully be considered here. From time to time during the last few years we have suggested that the cancer problem has entered upon a new phase, and the volume under review goes far to bear out our contention. Indeed, to the onlooker the situation is pregnant with possibilities. Intensive study has defined the nature of the malignant cell as it has never been defined before. The various disguises are being stripped from it one by one and its true features are beginning to be revealed. Like most other villains, it is not wholly bad. In many respects, as laborious observations and experiments have shown, it might pass unnoticed in a crowd of normal worthy citizens; yet we know very well that deep down its nature is essentially antisocial. At least one property peculiar to the malignant cell has been demonstrated beyond cavil by the recent work: it is the power to elaborate for itself growth-activating substances which are only produced in normal tissues by cell destruction. It has long been held that the stimulus to growth which causes the proliferation of the healthy cells at the periphery of any lesion, as part of the mechanism of repair, comes from the dead tissues, but the proof that this is really so was very clearly brought out by the method of tissue culture. Whereas embryonic and malignant tissues proliferate immediately if placed in a suitable culture-medium outside the body, adult tissues in similar circumstances exhibit a prolonged latent period of ten days or more before growth begins. This latent period may be abolished by the addition to the culture-medium of a saline extract of normal adult tissue which has been disintegrated and incubated at body temperature. In the destruction of normal tissue, therefore, an activating substance is produced which stimulates the proliferative powers of normal cells. Malignant cells yield a similar activating substance if extracted at 0° C.—that is, without any autolysis at all. This clear difference, then, is established between normal and malignant cells; the malignant cell produces autonomously activating substances which are only formed by the degradation of the protoplasm of the normal cell. The exact chemical nature of the activating substance is as yet unknown, but it seems scarcely likely that it will remain so for long, and with the detection of definite biochemical differences between the innocent and the malignant cell may come the opportunity of the experimental pharmacologist.

In another aspect of the cancer problem, that which deals with the actual production of malignant growths, much progress has also been made. Various forms of chronic irritation have long been associated with tumour formation, both on clinical and experimental grounds, and one of these, the repeated application of tar to the skin, has yielded results of the utmost value. With this method, superficial cancers which lend themselves well to observation can be produced with considerable uniformity in that convenient creature the mouse, as well as in other animals. Several significant observations have emerged from these experiments. In the first place, the time elapsing between the beginning of the tarring and the development of the tumour varies enormously in different animals, three and eighteen months being the minimum and maximum latent periods recorded. Further, cessation of the process of tarring after the applications have been continued for some two or three months does not prevent the malignant change. It would seem that while exposure over a certain period of time to some irritant is necessary to initiate the change, the actual development of malignant characters in a recognisable form is a slow and gradual process. The observations of DEELMAN, quoted in the report, are important as indicating the nature of the malignant change. This author has found that scarification of the skin of the mouse immediately before the tarring is started cuts down the latent period to something like a quarter of the time. In conjunction with the results of tissue culture, this observation strongly suggests that the trauma and the reparative changes following it, put the cells in a susceptible condition, so that they react more rapidly to the action of the tar. And all these experiments tend to show that the cell in becoming malignant actually acquires new properties; that malignant disease is not due to any inhibition, loss of physiological control, or alteration in tissue tension.

So far the experimental production of cancer has not rendered the situation more hopeful, but rather the reverse, for the assumption is that the cancer of middle life is due to factors potent many years before. But it may yet prove that salvation will be found in this latent period, as it is in hydrophobia, and further investigations suggest possibilities of far-reaching importance. In mice in whom tar cancers have been produced and extirpated by operation, the further application of tar to a different area of the body fails to produce anything more than atrophy of the skin; and similar negative results were obtained in 13 out of 14 animals from which spontaneous mammary carcinomata had been removed by operation. These experiments are admittedly few in number, but they are supported by others planned on slightly different lines, and they fit in with the rarity of double carcinomata in the human subject. While it is obvious that much more work must be undertaken in this direction before it will be possible to speak with certainty, the inference that a profound constitutional change is brought about in the individual by the development and growth of a malignant tumour is very strong, for only thus can this refractory state be explained. Granted the existence of this constitutional change, its recognition and even its control should not be beyond the bounds of possibility. Could it be demonstrated, it might prove of extreme value in diagnosis, while by its artificial production it might even be possible to inhibit the development of tumours.

Even from this brief summary of the report the scope and importance of the work being carried on by the Imperial Cancer Research Fund must be apparent. The close association between the various organisations engaged in cancer research in this country and abroad, combined with the modern facilities for the rapid interchange of experiences and ideas, have focused attention on this subject with an intensity never before approached. Progress since the war has been remarkable, and we are fully justified in hoping for much in the near future. A word of warning, however, is not amiss. We should be rash indeed were we to encourage the public to believe that the cure of cancer will follow immediately upon the attainment of a more complete knowledge of the cause of cancer, for there is no absolute justification for this belief. The tubercle bacillus was discovered some 40 years ago, yet tuberculosis is still rampant. It is one thing to recognise a whirlwind, it is quite another thing to direct a storm; and the medical profession will best retain the confidence of the public by remembering that there is safety in caution.

◆

A GREAT SEER.

Dr. Fournier D'Albe is to be congratulated upon having written a very charming as well as interesting biography[1] of one of the foremost scientific men of the day. Sir William Crookes's personality was a difficult one about which to write, but Dr. D'Albe has managed to be strictly impartial, thus avoiding the pitfall into which a certain legal luminary on the Bench is said to have fallen, when he concluded his charge to the jury by saying: "Gentlemen, you will give your verdict according to your consciences and the evidence which has been laid before you, avoiding partiality on the one hand and impartiality on the other." To take first the debatable side of Crookes's career—namely, his investigations and opinions upon what is called spiritualism—Dr. D'Albe gives an account of Crookes's position from the spiritualist point of view and from the rationalist point of view, and sets out the arguments pro and con with great fairness in Chapter XII. His conclusion is, "spiritualism as a religion may legitimately be studied in a section of anthropology, but spiritualism as a science does not exist."

It is both more pleasant and profitable to follow those portions of Crookes's long career which show him as the earnest and capable student of chemistry, as the founder of the *Chemical News*, as the worker in spectroscopy and the discoverer of thallium, as the inventor of the radiometer and the discoverer of cathode rays. One very remarkable feature of Crookes's researches was the scientific intuition which came to him from time to time when the balance of his intellect trembled on the verge of a great discovery without, however, quite coming down on the right side. Thus, on p. 26 his biographer quotes an entry from an old note-book under date April, 1854, upon an examination of the spectrum produced by coloured flames which shows that he was within an ace of discovering the law established by Bunsen and Kirchoff in 1859, that when light from a solid or a liquid passes through a gas of lower temperature the gas absorbs those particular rays of light of which its own spectrum consists. At the time of his spectroscopic research Crookes was in his twenty-second year. It is fair to state that Stokes in 1850 had suggested that the double dark line Frauenhofer D was due to the absorptive action of sodium vapour in the sun's atmosphere. Again, at p. 340, we are given excerpts from an article in the *Fortnightly Review* of February, 1892, based on observation of a few developments of the Hertzian demonstration of electric waves in space, which is a wonderful forecast of wireless telegraphy. Sometimes, however, Crookes underrated the possibilities of newly born inventions, as, for instance, when in 1878 we find him writing to Prof. (now Sir) William Barrett, "I don't think there is field yet for the telephone to be used commercially. I don't think Bell's company is doing much." His demonstration of electric discharges in high vacua at a meeting of the British Association at Sheffield in 1879 was the first time in which the phrase "cathode rays" was used. A little earlier than this date he had regarded the stream of cathode rays as corpuscular light. Now, however, he called them "matter in a fourth state"—i.e., he claimed, and rightly so as we now know, that he had obtained matter in a state not solid, liquid, nor gaseous, but split up into the apparently ultimate elements which we now call electrons.

Crookes was a striking example of the British scientific man who rises to great heights by the sheer force of genius, with little or no education in the vulgar sense of the word. He was born in 1832 the son of a tailor in Regent-street. His first school was at Weybridge, where he seems to have been like any other boy, though from his earliest years he was fond of chemistry and was always trying experiments. His early sound training in chemistry he obtained under that admirable teacher Hoffmann at the Royal College of Chemistry in South Kensington, and within a year of his entry in 1848, his sixteenth year, he obtained the Ashburton scholarship, while at the end of the following year Hoffmann appointed him junior, and in 1851 senior assistant. The story of his struggles and trials, of his never-ceasing work, of his discoveries and successes must be sought for in Dr. D'Albe's pages. Besides chemistry he worked in many side lines of scientific matters, such as photography, the separation of gold, explosives, and the cattle plague, for which disease he advocated the use of carbolic acid as a disinfectant and decided (this was in 1866) that the disease must be due to "germinal matter, or living cells, possessing physiological individuality." Perhaps the occasion on which Crookes came most prominently before the public was in 1898, when as President of the British Association he delivered a remarkable address upon the wheat problem, the value and importance of nitrogen, and the discovery by William Ramsay of new gases. It is worth while quoting his striking peroration :—

---

[1] The Life of Sir William Crookes, O.M., F.R.S. By E. E. Fournier D'Albe, D.Sc., with a foreword by Sir Oliver Lodge. London: T. Fisher Unwin, Ltd. 1923. Pp. 412. 25s.

> "In old Egyptian days a well-known inscription was carved over the portal of the Temple of Isis : 'I am whatever hath been, is, or whoever will be ; and my veil no man hath yet lifted.' Not thus do modern seekers after truth confront Nature—the word that stands for the baffling mysteries of the universe. Steadily, unflinchingly, we strive to pierce the inmost heart of Nature, from what she is, to reconstruct what she has been, and to prophesy what she yet shall be. Veil after veil we have lifted, and her face grows more beautiful, august and wonderful, with every barrier that is withdrawn."

Eleven years later—namely, in 1919—Crookes died in his eighty-seventh year, and with the words quoted above we may leave him, for no words can better express the way of his life.

SPA TREATMENT AND DIURESIS.

The mere fact that a method of treatment has enjoyed widespread popularity through many centuries is in itself strong evidence in favour of the efficacy of such therapy, nor must we allow the possible absence of any final knowledge of the mechanism of such a method to make us sceptical as to its real value. The pharmacopœia is a catalogue of mysterious agents, and the triumphant elucidation of the action of a sparse handful of them is ample justification for our continued use of the remainder pending the day when their exact properties will be demonstrated. We must adopt the same attitude of expectant faith towards many other medical methods, and such must be our consolation in following the discussion on the diuretic action of spa waters which took place before the Section of Balneology and Climatology of the Royal Society of Medicine and was reported in our columns last week. The continued prosperity of numerous baths and spas which have been celebrated since the Roman epoch is abundant testimony to their powers, and it is impossible to dismiss their good effects as being merely the result of the abstemious régime imposed by the local victuallers.

The discussion itself cannot be said to have thrown any clear light on the action of these waters. Dr. C. W. Buckley, in his opening address, was at pains to admit this. He drew attention to the fact that the concentration of salts present in such waters is often much lower than that required to provoke diuresis when administered in artificial solution. There is not even any clear consensus of opinion as to which elements have or have not a definitely diuretic effect, Keller and Violle holding that NaCl is definitely antidiuretic whilst a host of pharmacologists maintain the contrary opinion. Effects of the waters of various springs upon nitrogen excretion are equally obscure. Extravagant claims, such as that the total daily excretion of nitrogen is increased to a notable degree, may be dismissed at once, but that some alteration in the proportion of the various nitrogenous constituents of the urine may be produced is strongly suggested by several recent researches, though in this respect the comment of Dr. W. Langdon Brown, who pointed out the wide normal variation in these constituents due to diet, must be borne in mind. In face of these difficult problems there is a tendency to seek explanations in the most recent and possibly most nebulous realms of biochemistry. Thus it was suggested by one speaker that some spa waters reduce the hydrogen-ion concentration of the blood, an effect which would, in the view of eminent physiologists, be rapidly fatal if it were possible of achievement. Others seek enlightenment by studying the radioactive properties of various springs ; that such waters are sometimes radioactive is certain, but, as Dr. Buckley pointed out, there is as yet no evidence that their diuretic properties are due to such agencies.

Recent work [1] has shown that the ingestion of water alone, without a corresponding excretion, may produce symptoms resembling uræmic convulsions, and even a fatal effect when the intake is prolonged for any length of time. These observations were made on large series of animals under careful laboratory control, and it seems probable that it is only when spa waters are similarly studied with the aid of carefully controlled experiments that we shall secure any true insight into their properties and effects.

MEDICINE IN HOLLAND.

Education stands high in Holland. We in this country can hardly challenge comparison with a State of 7,000,000 inhabitants which has no less than three State universities—Leiden, Utrecht, Groningen ; a municipal university—Amsterdam ; a technical university—Delft ; a veterinary university—Utrecht ; and an agricultural university—Wageningen : leaving out of account altogether military, trade, and art academies and private religious institutions. Four of these universities have a complete medical faculty, and together they find occupation for nearly 75 professors teaching purely medical subjects, not including the ancillary sciences. The compulsory term of study for the State medical diploma is seven years, five of which must be devoted to clinical work, and in spite of this very high standard, on an average about 100 medical students qualify each year. In the near past, students from the Netherlands, although polyglot, have, as a rule, been able to follow the German language more easily than English or French, and were to be seen attending clinical courses in all the German-speaking medical schools of Europe, for it is the continental fashion to spend at least a summer semester away from the home school. We are glad to give in another column some information from a Batavian correspondent on current medical affairs, for we regard the time as ripe for a closer understanding between medicine and its disciples in the two countries. Prof. E. H. Starling pointed out not long ago that the unique geographical position of Holland designed it to bring this country into touch with modern European thought. Through the efforts of the Anglo-Batavian Society we have already learned at first hand of the work of Prof. Hijmans van den Bergh and of Prof. C. Winkler, both of Utrecht. There seems to be an increasing interest amongst medical students in Holland for English and American periodicals and manuals, and the pre-war statement is no longer true that 80 per cent. of students use nothing but German text-books. The medical world in Holland, as here, bears the stamp of its national peculiarities, and medical entente can only be served by mutual understanding of the scientific, practical, and social points of view of the two nations.

Annotations.

"Ne quid nimis."

THE PREVALENCE OF INFLUENZA.

THERE has been the usual sharp seasonal rise in the deaths from influenza and respiratory disease, attended with the usual questioning as to the prospect of a serious epidemic of influenza. There is no simple arithmetical rule for prophets, and the only indications at our disposal of an approaching epidemic of respiratory diseases are (1) deaths ascribed to influenza, and (2) notifications of pneumonia. With regard to (1), there is a relatively heavy increase in the numbers of deaths both in London and the 105 great towns—the number was 103 in the week ended Dec. 8th, as against 68 in the previous week. There are also small but definite increases particularly in the great towns of Lancashire (included, of course, in the total 105 great towns). The age-distribution of these deaths is similar to that observed in the influenzas prior to 1918–19; in other words, there is no sign of the sharp change of type which was the most disquieting feature of the great pandemic. With regard to notified pneumonia, there has been a tendency to rise for some weeks, and last week there was a large increase in the North-Western area, while Yorkshire, which is usually affected early by respiratory epidemics, is now reporting many cases. The difference, however, between the notification rate this year and that of 1922 is not very great. So far as this evidence goes, the present may be regarded as a minor recrudescence, probably favoured by the fogs of last month, and perhaps by the crowds associated with the General Election.

ÆTIOLOGY OF BLACKWATER FEVER.

ALTHOUGH evidence has been accumulated all over the world that the constant factor associated with hæmoglobinuric fever is malaria, and, further, that it is the malignant tertian parasite (*Plasmodium falciparum*) which alone is concerned with the production of this disease, many observers have attempted to find another causal organism. Various organisms have been described other than malaria as the probable cause of blackwater fever, but these have all been discarded. More recently spirochætes or a special species of this group have been suspected, and in 1912 Napier favoured the view that syphilis predisposed to this condition, but Barratt and Yorke (1909), Arkwright and Lepper (1918), and Dudgeon (1921) showed there was no connexion between the two diseases. On the other hand, there is strong evidence that syphilis is the predisposing cause of paroxysmal hæmoglobinuria. True spirochætes have been found associated with hæmoglobinuric fever. Ashburn, Vedder, and Gentry, in 1912, and Cook, in 1913, described this disease associated with relapsing fever, and Schüffner (1920) described a case complicated with an attack of acute infective jaundice. Noc and Esquier (1920) found numerous spirochætes in the liver of a fatal case. These findings, however, can only be regarded as the accidental accompaniment of one disease with another. More recently Blanchard and Lefrou in 1922, using a special technique by which the citrated plasma of 10 c.cm. of blackwater fever blood was subjected to triple centrifuging, described leptospira in the deposit from three cases. The deposit from one of these cases inoculated subcutaneously into guinea-pigs produced a fatal disease, and in one of the subinoculated animals hæmorrhages were found in the peritoneal cavity and in the bladder.

Dr. J. G. Thomson, director of protozoology, London School of Tropical Medicine, who has made two expeditions to Rhodesia in 1922 and 1923 to study hæmoglobinuric fever in that area, used Blanchard and Lefrou's technique in order to confirm the work of these observers. The result of the investigation of the first six cases proved negative.[1] Low and Duncan confirmed this work shortly afterwards in one case, and more recently Thomson has brought forward conclusive evidence [2] that blackwater fever develops as the result of repeated attacks of malignant tertian malaria. The blood of 15 cases of blackwater fever was examined at different stages of the disease from the first day until recovery by Blanchard and Lefrou's method with universally negative results. The conclusion arrived at is that the numerous motile filaments seen under the dark ground illumination in all these cases and in normal cases are the well-known artefacts which have so often been mistaken by other observers in the blood of various diseases for the causal organism of such diseases. Subinoculations in guinea-pigs failed to produce any symptoms or pathological changes. From this it is concluded that there is at present no evidence that spirochætes or a special species of spirochæte are responsible for blackwater fever, and the relationship of malaria to this condition is regarded as undoubted.

A PIONEER OF PUBLIC HEALTH.

Two years ago the University of Manchester lost a valued fighter in the field of public health through the death of Prof. Delépine, and on Dec. 12th last there was unveiled to his memory a portrait bust, erected in the Public Health Laboratory of the University by former colleagues and students. The bust bore the following inscription: "Auguste Sheridan Delépine. Born January 1, 1855. Died November 13, 1921. Founder and first director of the Public Health Laboratory. Professor of Pathology 1891–1904. Professor of Public Health and Bacteriology 1904–21." The unveiling ceremony was performed by Sir George Newman, who spoke in feeling terms of the work Prof. Delépine had accomplished, for the University, for the city of Manchester, and for the public health of the nation. An outline of that work was given in THE LANCET (1921, ii., 1080), and we would here record the personal tribute paid to the worker by the Chief Medical Officer of the Ministry of Health. Prof. Delépine, said Sir George Newman, was a pioneer in associating a university with the training and work of the medical officer of health. He held strong and liberal views, springing from deep and sincere convictions, as to the value to the community and to the nation of the public health service, inculcating high ideals for public medical officers, and extending in various directions the ever-widening sphere of their work. He gathered round him a remarkable group of earnest students who gladly learned at his feet and in after years preached his gospel in various parts of the land. For he was an inspiring teacher, especially to the few, and he won the admiration and affection of his pupils. In the study of disease Delépine was chary of anything which tended to lessen the responsibility of the seeker. In his last published paper he wrote regarding the cause of disease: "I think it is better to attach too little than too much importance to personal predisposition, for the doctrine of predisposition has the same influence in medicine as that of predestination in religion; both tend to make us overlook our responsibilities."

Prof. Delépine, of French descent though a naturalised Englishman, was a man of very original mind, fertile in idea, acute in perception, resourceful in the invention of the ways and means of research, precise in its exercise, and meticulous in its findings. He was widely read in the literature of medicine and its allied sciences, with a retentive memory and a broad outlook, and able to utilise and apply the knowledge which he acquired. While possessing these exceptional gifts, Delépine was an indefatigable workman and was laboriously conscientious, reluctant to publish his results until he was satisfied that his conclusions were valid and invulnerable. An enthusiastic believer in preventive medicine and its potential influence in the life of human society, he became an inspirer and encourager of others. Though he failed to win some of the world's glittering prizes, he became something of a national leader in his subject, devoting his life and sacrificing much in order to establish a great school of public health at Manchester University. The master-word was work, and the purpose was production and service; in fact, Delépine seems to have compounded in himself some of the fundamental requirements of the new model of public health officer. He had in no small degree two of Pasteur's chief characteristics—love of truth and love of humanity. He sought truth and pursued it, and he was prepared to follow truth wherever it led. And more than that, he bent himself, through 30 years, to the task of applying knowledge to the improvement of man's estate and of directing truth to the growth and emancipation of man's mind. It is a great and splendid thing, Sir George Newman concluded, for a university and city to have such a man as Delépine. To him was given the reward foretold by Thucydides —namely, the grandest of all sepulchres, not only that in which his mortal dust is laid, but a home in the minds of men where his glory remains, carved not in stone but woven into the stuff of other men's lives.

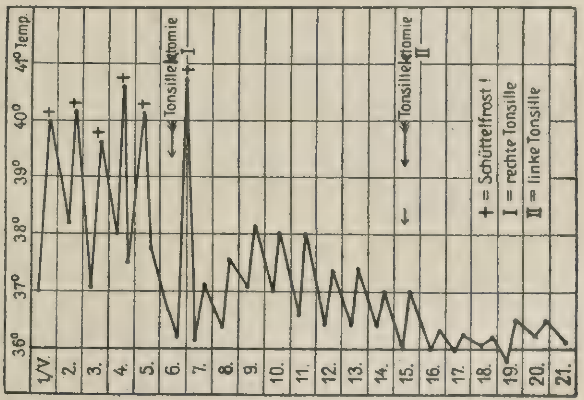
SICKLE-CELL ANÆMIA.

Dr. John G. Huck,[1] of the Biological Division of the Medical Clinic of Johns Hopkins University and Hospital, who reports 14 illustrative cases, defines sickle-cell anæmia, which was first described by Herrick in 1910, as a hereditary disease transmitted by and occurring in both males and females with equal frequency, in which the red corpuscles acquire a characteristic sickle or crescent shape. There are certain characteristic clinical symptoms, especially anæmia and leg ulcer. All the cases hitherto reported have occurred in negroes or mulattoes. No post-mortem findings have been recorded. The leg ulcers have the round, punched-out, and indurated appearance of syphilitic ulcers, for which they are often mistaken. The base of the ulcer is composed of granulation tissue possessing no characteristics suggestive of a specific ætiology. The surface is clean and there is a total absence of any necrotic membrane overlying it. The blood flows and coagulates normally in all forms of the disease. The number of red cells ranges from 1,500,000 to 4,000,000, and the hæmoglobin from 30 to 40 per cent. The colour-index is usually normal or high. The leucocytes are slightly increased in number, ranging from 10,000 to 20,000. Films show a moderate anisocytosis and poikilocytosis, which occurs most frequently during relapses. The poikilocytosis consists of crescentic or sickle-shaped cells with an occasional oat-shaped cell. There is a moderate degree of polychromatophilia. Nucleated red corpuscles of all varieties are present, but normoblasts are especially common. The differential formula of the leucocytes is not characteristic. The polymorphonuclear neutrophile cells are usually increased in number, and there is sometimes an increase of the polymorphonuclear eosinophiles or small lymphocytes. Large mononuclears, which may be seen engulfing red corpuscles, are sometimes present in large numbers and may be responsible for the anæmia. The number of blood-platelets is increased, ranging from 300,000 to 500,000. On examination of fresh preparations of the blood only a few red corpuscles with a crescent or sickle shape are seen at first, but after 6 to 24 hours from 25 to 100 per cent. of the cells, according to the severity of the disease, assume this form. Clinically, cases may be classified into symptomless, mild, and severe. Those who have no symptoms go through life like normal individuals, and it is only by the chance examination of incubated samples of fresh blood that the diagnosis is made. In mild cases the chief symptoms are weakness and fatigue, and occasionally muscular and joint pains, which disappear after rest in bed. In severe cases the chief symptoms are inability to work due to weakness, leg ulcers, muscular pain and stiffness, and often sharp pain in the epigastrium, especially after food. Fever is usually present, but the temperature is rarely higher than 101° F., unless there is a superadded infection such as tonsillitis, to which the patients are usually susceptible. Remissions and relapses lasting three to six weeks are frequent. In the symptomless and mild forms the prognosis is excellent, but in the severe forms it is unfavourable owing to suceptibility to intercurrent affections, especially pneumonia and tonsillitis. The condition has never been cured, but under treatment by simple hygienic measures, rest in bed, and administration of iron and arsenic, the relapses are shortened and the remissions made longer.

CHRONIC TONSILLITIS AND PUERPERAL SEPSIS.

A REMARKABLE instance of the result of a chronic tonsillar infection on puerperal infection is reported by Dr. Otto Blass,[1] of Bielefeld. The patient, aged 27, developed a high temperature with rigors three days after being delivered of a premature infant. A few days later a painful swelling of the right thigh appeared, and for the next seven weeks the pyrexia curve remained septic in character, with a daily rigor. During this time she had an acute attack of tonsillitis. (She had previously suffered with repeated infections of the pharynx.) At this stage she was admitted into the hospital in a deplorable condition of emaciation. There was marked trismus, the tongue was dry and cracked, temperature 39·2° C., pulse 130, and commencing decubitus was present. The abdominal wall was rigid, infiltration of the right parametrium could be felt, and there was a tender swelling in the right groin. Staphylococci were grown from the blood, the leucocytes numbered 23,800 per c.mm., and the urine contained hyaline and granular casts. For the next few days the temperature swung up daily to 41° C., in spite of intravenous injections of silver preparations, rivanol and chinin, the general condition becoming worse and the trismus increasing. This condition, together with the onset of aural pain, led to the diagnosis of a tonsillar infection, and tonsillectomy was performed first on the right side and later on the left. The right tonsil was found to have a small peritonsillar abscess, but the left only showed slight changes. The result of this procedure is best demonstrated by the temperature chart. With the fall of the temperature the general condition improved rapidly, the œdema of the leg and the swelling in the groin disappeared, the blood became sterile, and the urine showed no pathological changes. When the patient was discharged, apart from slight adhesions drawing the uterus over to the right, the pelvic examination revealed nothing abnormal. It is



Temperature chart, showing times of right and left tonsillectomy and rigors. (†)

[1] Deutsche med. Wochenschrift, Nov. 16th, 1923.

possible that puerperal infection is more often than we think the result of a hæmatogenous metastasis rather than an external infection, and a more exact investigation for a possible focus might well be made in many cases. Dr. Blass mentions a second case in which tonsillectomy brought about marked improvement and caused the blood to become sterile, although unfortunately the patient died of broncho-pneumonia.

X RAY EFFECTS ON TISSUE CULTURES.

AN important contribution to the study of the changes observed in tissue cells after exposure to soft X rays was recently made by Dr. T. P. Strangeways and Dr. H. E. H. Oakley to the Royal Society.[1] The tissue cells were those from the choroid of chick embryos of six to seven days' incubation and they were cultivated in vitro. The cultures were exposed to X rays for various lengths of time while at incubation temperature. In each experiment four cultures were exposed to the X rays, two were stained immediately, and two were returned to the incubator for 80 minutes before staining. The authors describe in detail with the aid of some beautiful drawings the changes noticed in the cells under these various conditions. In common with several previous investigators the authors find that the cells in active mitosis are more vulnerable to the rays than the cells in the growing stage. The alteration in mitosis may be of quite a temporary nature, for the authors find that if cultures in which mitosis has ceased owing to irradiation are returned to the incubator for some hours, cells in mitosis are again found. Certain granular changes and fragmentation of the chromosomes at metaphase and anaphase may occur without an actual cessation of mitosis; if the radiation is prolonged the daughter cells show abnormalities and may contain two or three nuclei. The authors often refer to "breaking-down cells." The changes in growing cells are far less frequently seen than in dividing cells, but when the cells are watched on a warm stage the movements and changes of outline of the cytoplasm, nucleus, and nucleolus point to a disorganisation of the cell; in some cases the whole cell appears to go into solution in the surrounding medium. These studies are an important contribution to what we may call the direct action of X rays upon cell life. An extension of the work to other varieties of tissues can hardly fail to give valuable information upon lethal ratios for the dividing and growing cell. The bearing of such data upon therapeutic measures needs no emphasis.

TRAUMATIC MYOSITIS OSSIFICANS.

DURING the discussion on myositis ossificans traumatica, which took place at the Orthopædic Section of the Royal Society of Medicine, and which is reported on p. 1350 of our present issue, certain points were brought forward which are of the utmost importance to the general practitioner. The treatment of this condition was considered particularly from the point of view of its prevention. It is well known that this new formation of bone most often follows dislocations or fractures about the elbow in children; and whilst it cannot always be prevented, certain factors with regard to the causation are known. Following any injury about the elbow which involves tearing of periosteum, heavy massage, forced movements—erroneously called passive movements—or rough handling of the part are contra-indicated. The dislocation should be reduced, or in the case of fracture the displaced fragment brought into correct alignment by careful manipulation under anæsthesia. When there is a supra-condylar fracture, reposition of the lower fragment into correct alignment with the upper is the essential point. If this is attended to and rest enforced the result will be satisfactory, and full movement of the elbow-joint will be regained. The elbow should be put at rest in the flexed position by slinging the wrist to the neck. This method of fixation was originally described by Hugh Owen Thomas in the seventies of the last century, under the term "gauge halter." No physical treatment should be attempted for ten days, after which the sling is lengthened and the elbow allowed gradually to extend so long as the patient retains the power to regain the flexed position voluntarily. If the power of voluntary flexion is lost, the elbow should again be flexed for a few days by shortening the sling, after which it is again gradually allowed to extend. Gentle massage may be employed after ten days, but no deep kneading is to be permitted. No attempt must be made to regain movement rapidly, as for example by forced movements under anæsthesia. In the early stages such manipulation will result in greater stiffness rather than in increase of mobility, and there is in addition a grave danger of setting up the process of new bone formation in the muscles—myositis ossificans.

The importance of rest rather than movement after an injury in the neighbourhood of the elbow, especially in children, cannot be over-estimated, and its value is not sufficiently appreciated. For whilst recovery of function is regained by rest, the development of bone the production of myositis ossificans is a definite risk, which is run if force be employed. If myositis ossificans has resulted from the injury the treatment called for is again complete rest of the limb. No massage or movement must be permitted, but the elbow should be fixed in a sling in the position of flexion. The new bone will gradually become absorbed. A series of lantern slides were shown at the meeting, illustrating the complete absorption of the new bone in the course of a few months' rest. No operation should be undertaken to remove bone for at any rate six months, and until rest and fixation has had a long trial. Whilst the removal of an osteophyte blocking movement in a joint will often succeed, the results of operation on true myositis ossificans are poor. Any question of operation should be postponed for a long period, and only undertaken after careful examination, when the main mass has been absorbed and the remaining part is dense and incapable of natural absorption. Even at this late stage the results of operation are disappointing.

BITEMPORAL CONTRACTION OF THE FIELDS OF VISION IN PREGNANCY.

VARIOUS writers during the last 20 years have observed a certain degree of contraction of the visual fields on the temporal side during the late period of pregnancy. Dr. G. E. de Schweinitz, in his recent Bowman lecture,[1] on certain ocular aspects of pituitary body disorders, referred to this subject. He stated that out of 13 unselected cases of gravid women admitted to a maternity department in nine cases there was a definite contraction on the temporal side of the field from 15° to 40°. He also referred to a research on this subject by Dr. Maud Carvill, of Boston, Mass., more elaborate than any other on record. The completion of this research is now published.[2] Out of an unselected number of gravid women, the progress of whose pregnancies was normal, the visual fields were examined in 100. In the case of 12 of them the examination was conducted more than three weeks before parturition, and in their case no contraction of the visual fields was observed. On the other hand, among the remaining 88, in whose case the examination was made within three weeks of parturition, only five cases had normal fields, while the remaining 83 cases showed bitemporal contractions of greater or less extent. In 22 cases it was marked (20° or more); in 50 cases it was moderate (10° to 20°); in 11 cases it was slight (5° to 10°), contractions under 5° being taken as not outside normal range. After parturition in the great majority of cases the fields showed complete recovery. In 51 of the cases examined post partum all but two showed normal fields, an observation which accords with the experience of other observers. There seems no doubt that the cause of this phenomenon is an enlarged pituitary body pressing on the optic chiasma. That this enlargement actually takes place was shown by J. Erdheim and E. Stumme in 1909, who demonstrated the fact by the examination of 150 subjects.[3] They found that in women who had never been pregnant the average weight of the hypophysis was 61·8 cg., the maximum 75. In primiparæ the average was 84·7 cg., the maximum 110. In multiparæ the average was 106 cg., the maximum 165. After parturition there occurs a subsidence, but the increase in the number of cells is never entirely lost. The clinical investigation of Dr. Carvill shows a remarkable correspondence with these pathological observations.

THE V.A.D.'S.

THE vision at once conjured up to most of us by the well-remembered initials V.A.D. is that of devoted and skilful service, in the theatres, wards, and kitchens of hospitals and convalescent centres during the war by amateurs who gently insisted on making a valued place for themselves in ranks where professionals formerly held undisputed sway. It is inevitable, perhaps, that the duties and responsibilities of the voluntary aid detachments should seem of less importance in times of peace, but their activities must not be lost to the community for want of encouragement and organisation. Moreover, it is to be remembered that though the familiar white head-dress and grey or blue frock stands out in our memory, the V.A.D.'s were not confined to one sex or to one service. It is gratifying that a scheme[4] for voluntary aid detachments to supplement the medical services of the Navy, the Army, and the Air Force in time of war has been approved by the Army Council. The medical services of the forces of the Crown are regarded as sufficient to meet ordinary peace requirements, but they lack certain reserves needed on either partial or general mobilisation. On the outbreak of war, therefore, these services will require the assistance of personnel of voluntary aid detachments. These reserves will be required for motor ambulance convoys, ambulance trains, general, naval, military and air force hospitals, auxiliary hospitals, rest stations, hospital ships, convalescent homes, command depôts, and entraining, detraining, embarking, and disembarking sick and wounded. The administration of voluntary aid detachments is vested in a joint council representative of the Admiralty, War Office, Air Ministry, Territorial Army Associations, Order of St. John, British Red Cross Society, and St. Andrew's Ambulance Association. The Council may authorise the appointment of committees in the United Kingdom or the British Dominions and may delegate certain powers to such committees.

Territorial army associations will be responsible for the enrolment and efficiency of voluntary aid detachments in close coöperation with the joint county committees or the body or bodies which train the personnel in their respective areas. The chief executive officer for voluntary aid detachments in any area shall be the county controller, whose duties include the organisation and maintenance of local detachments, the assumption of responsibility for the efficiency of members, the arrangements for periodical inspection and for preparations for mobilisation as indicated by the military authorities, and the rendering of returns to the appropriate office. As to enrolment a voluntary aid detachment may consist either of men or of women, but not of mixed detachments. Only British born subjects, including those of the Dominions, are eligible for enrolment. Every applicant on joining must sign a form of enrolment, and also an obligation to undertake service when called upon in the class and category in which he or she is enrolled. The following grades shall be considered officers: Controllers and assistants, commandants and assistants, medical officers, lady superintendents, quartermasters. Members of detachments will be divided into two classes: (*a*) mobile, (*b*) immobile. In the case of men the mobile members, who shall be between the ages of 19 and 40, must be prepared to undertake service with any portion of His Majesty's forces on mobilisation, either at home or abroad, in accordance with the regulations which shall be in force. The immobile members will undertake service within reach of their own homes, and must not be under the age of 18. Men enrolled for general service may be employed on any of the following duties: Stretcher-bearers, clerks, carpenters, mechanics, motor drivers, cooks, storekeepers or store accountants, radiographers, nursing orderlies, laboratory assistants, masseurs, sanitary orderlies, or any other related duties. All members must be thoroughly trained as stretcher-bearers, and a proportion must also hold certificates in home nursing, hygiene, and sanitation. Every member of a detachment must pass an annual efficiency test, and must attend the annual inspection. As to women members of detachments the regulations of mobile and immobile classes are identical with those governing the men. Women may be employed on any of the following duties: Nursing members, pharmacists, dispensers, radiographers, ward orderlies, hospital cooks, stewards, storekeepers, hospital clerks, ambulance motor drivers, dental mechanics, masseuses, laboratory assistants, optical assistants, telephone operators, and must, in most cases, have taken the certificates in first aid and home nursing.

Further information on qualifying certificates, registration, inspections, appeals, and training are included in the scheme, which is likely to revive and consolidate the interest in a movement which did so much to help us win the war. The offices of the Central Joint Voluntary Aid Detachment Council are to be at 80, Pall Mall, London, S.W., and its secretary is Lieut.-Colonel W. H. A. De la Pryme.

TUBERCLE BACILLI IN THE URINE.

HOW often do tuberculous lesions of the kidney occur in patients suffering from pulmonary tuberculosis? Can tubercle bacilli be excreted in the urine by a kidney showing no evidence of tuberculosis? Dr. F. Bedo Hobbs has attempted to answer these and cognate questions in the November and December numbers of *Tubercle*. His investigation of the records of 1000 necropsies on patients dying of pulmonary tuberculosis at the City of London Hospital for Diseases of the Chest, Victoria Park, showed that in 162 cases, or 16·2 per cent., tuberculous lesions of the kidney were found. The findings of other observers, collected by Dr. Hobbs, showed an average of 16·9 per cent.—a remarkable confirmation of his own figures which are concerned with macroscopic examinations. He has also examined a small number of kidney sections microscopically, and has found signs of tuberculosis in 32 per cent. In only a very small percentage of his 1000 cases had there been any signs of renal tuberculosis during life, and only in five cases did the disease involve the whole of one kidney, causing widespread infiltration and ulceration. Among the 55 unilateral cases in his series, the right kidney was affected in 32, and the left in 23 cases. In 100 cases of pulmonary tuberculosis without urinary symptoms he examined the urine for tubercle bacilli, guinea-pig tests being carried out by Dr. S. Roodhouse Gloyne and Dr. D. S. Page. Positive results were obtained in six cases, and in one of the cases which came to necropsy a careful microscopic examination failed to reveal any evidence of tuberculosis of the kidneys, bladder, or genital organs. Presumably, therefore, the tubercle bacilli had been excreted by a healthy kidney. This is a most important observation, as it shows that the presence of tubercle bacilli in the urine is not necessarily indicative of tuberculosis of the urinary tract. With regard to the mode of infection of the kidneys, Dr. Hobbs comes to the conclusion that the bacilli are usually carried there by the blood-stream and very seldom by the ureters or lymphatics. Although in several cases the lesions were confined to the cortex, in none was the medulla affected without tuberculous changes being found in the corresponding portion of the cortex. The lines of round-cell infiltration found connecting the cortical and medullary lesions suggested that there was a direct spread from the former to the latter, probably through the lymphatics. One of the main conclusions to which Dr. Hobbs comes is that just as tubercle bacilli may enter the body without leaving any lesion at the port of entry, so they may be excreted without producing any lesion.

PRICE AND UNIT VALUE OF INSULIN.

The Medical Research Council announce that the retail price of insulin in this country is to be reduced by the manufacturers,[1] after Dec. 31st, 1923, to 12*s.* 6*d.* per bottle of 100 units. The price of this quantity since July has been 17*s.* 6*d.*, and before that the price was 25*s.* A reduction of 50 per cent. has accordingly been made since insulin first came on the market nine months ago. This is to be attributed to the increased efficiency of manufacture and to the larger scale of production following the growing demand. It is of interest to compare the progressive reduction in price here with the corresponding fall in America. It must be remembered, however, that the American manufacture began some months before the British, that the demand and consequently the scale of production is larger there, and that advantages in respect of large slaughtering centres and lower cost of alcohol exist in America which are not enjoyed by the British firms. In April last the retail price in America, formerly higher, was 2*d.* per unit, or 2¼*d.* in an alternative dilution ; the price here was 3*d.* per unit. The American price was then reduced to just over 1½*d.* per unit, and in July the British price fell to approximately 2*d.* per unit. A more recent reduction in America brought the price there to just under 1¼*d.* per unit, and the new British price is 1½*d.* per unit.

Some further reduction in price may be found possible by the manufacturers in the course of time as the scale and therefore the economy of production increases. It is not, however, to be expected—apart from the possibility of new sources or methods being discovered—that the price can ever be brought to a low level. The manufacture of insulin on a commercial scale involves the collection of large quantities of pancreas in very fresh condition, the use of large amounts of alcohol, elaborate and delicate chemical operations requiring skilled supervision, and careful physiological testing at different stages. The cost of such items must remain high in a process which gives a small yield of the final product.

The manufacturers of the American insulin announce an increase of 40 per cent. in the value of the unit of activity, and quite properly give a scale of dosage for their product revised in accordance with this increase. This announcement makes it advisable to explain the relation of the American unit to that adopted in this country. The Medical Research Council were made aware in August of this year of the discovery of a divergence between the unit adopted in Canada and that adopted by the manufacturer in the United States. They gathered that a proposal was under discussion to remove this difference by raising the value of the American unit by about 40 per cent. At that time American insulin had for a period not been in use in this country, and investigation showed that, during the interval, the value assigned to the British unit had been rising gradually, until it had become so nearly equivalent to the Toronto unit that a very small further adjustment was needed in order to make it correspond to the higher value which, in due course, came into force for the American continent. The value of the unit employed for British insulin is, therefore, already the same as that of the newer and stronger American issue ; the only difference between the two countries, in this direction, has been that the value of the American unit has been suddenly raised, so that revision of dosage is needed, whereas that of the British unit has been allowed to rise by small stages, so that dosage has, in practice, adjusted itself. Henceforward all the insulin available in this country will, as originally planned, be standardised to the same unit.

The reduction of price mentioned above has been made in spite of this enhancement in the strength of the unit, so that the total effective reduction in cost to the patient is much larger than appears from the figures of price revision.

TREATMENT OF MELÆNA NEONATORUM.

Melæna neonatorum would seem to be one of those conditions which were regarded as most alarming and refractory to treatment a generation ago, and which now are viewed with comparative equanimity. It is a curious fact that though the mortality from melæna neonatorum has shown a marked decline, and this decline is largely due to advances in treatment, our knowledge of the underlying causes is still very imperfect. About 30 years ago the mortality was said to range from 40 to 84 per cent. This mortality came down with a run when Guttmann in 1890 introduced gelatin, which was given by the mouth or by rectal or subcutaneous injection. There were, however, several objections to this treatment: the gelatin might contain the spores of tetanus, and though maternity hospitals might always have a stock of gelatin ready, the practitioner could hardly be expected to add it to his already overloaded equipment. A few years ago the Americans, Schloss and Commisky, advocated the injection into the subcutaneous tissues of the infant's buttocks whole blood taken from a vein in the mother's arm. In a paper in the *Schweizerische medizinische Wochenschrift* for Nov. 8th, Dr. R. L. Rochat, attached to Prof. G. Rossier's maternity hospital in Lausanne, has given an account of this procedure which he has found as simple as it is effective. All the equipment needed is a 10 c.cm. syringe. About 3 c.cm. of the blood aspirated from a vein in the mother's arm are injected into the infant's buttocks at once, before the blood has had time to coagulate in the syringe. These injections are repeated several times during the first day. It is not clear how such an injection acts, but it is probably no coincidence that all the substances which, on subcutaneous injection, hasten the coagulation of blood, contain protein. And although most proteins would doubtless have a beneficial effect when injected in cases of melæna neonatorum, it is obvious that few are available in an emergency, and the great merit of the procedure recommended by Dr. Rochat is its simplicity. Since 1904 there have been 20 cases of melæna neonatorum in his hospital where the treatment with gelatin has, since 1921, given place to transfusion of blood in the manner described. Only four of the 20 infants died, and in one of these cases there was not time even to attempt treatment. A generation ago it was assumed that syphilis and infection of the gastro-intestinal tract were the chief causes of this condition, but in 19 of the 20 cases there was no evidence of syphilis, and only in one case were there signs of septicæmia in the infant. In as many as eight cases the infants were born before term, but only in two cases had there been difficult labour to which the hæmorrhage might conceivably be traced. It is unsatisfactory that we still know so little of the underlying causes of melæna neonatorum, and it is a little disconcerting that our treatment, though successful, must still be regarded as empirical.

H.M. the King has become Patron of the Royal Society of Tropical Medicine and Hygiene.

---

[1] We are informed that Insulin "A.B." Brand (Allen and Hanburys, British Drug Houses, Ltd.) will be supplied from Jan. 1st, 1924, in (1) phials containing 5 c.cm. or 100 units or 10 doses at 12*s.* 6*d.* each, or (2) phials containing 10 c.cm. or 200 units or 20 doses at 25*s.* each.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

L.—THE TREATMENT OF EPISTAXIS.

In order to understand the rational treatment of epistaxis, certain premises have to be borne in mind; such are the age incidence, the position of the hæmorrhage, and the ætiology of the condition. Rare in young children, its frequency increases from the age of five up to adolescence, when it is at its maximum; then gradually diminishes, to increase again with advancing years when it is seen in its gravest form. It is found more commonly in males than in females. The bleeding occurs from one of four positions, the commonest being in what is known as Little's or Kiesselbach's area; this is situated on the septum half an inch behind its anterior edge and a quarter of an inch above the floor. Quite 90 per cent. of all cases occur from this area, where there is a close anastomosis between the spheno-palatine, anterior ethmoidal, and a septal branch of the coronary arteries and their accompanying venules. The other three sites are: a spot on the septum opposite the anterior end of the middle turbinal; the anterior end of the inferior turbinal; and, as pointed out by Kelly, a profuse venous hæmorrhage may occur high up from the anterior ethmoidal veins, these veins anastomosing with the veins of the dura mater and with the superior longitudinal sinus. The ætiological factors are numerous and are best classified into local and constitutional.

Local Factors and Constitutional Factors.

The chief local causes are: traumatisms, accidental or surgical; ulcerations of various types; new growths—especially sarcoma and septal angeioma or "bleeding polypus"; certain nasal diseases, especially atrophic rhinitis and rhinitis sicca, in which crust formation occurs, the separation of these crusts, either automatically or intentionally, leading to excoriation and hæmorrhage. This crust formation, with its accompaniment of nose-picking, is one of the common causes of nose-bleeding in children, in whom epistaxis is also a symptom of the presence of adenoids; when unilateral and accompanied by a muco-purulent discharge it is usually the result of a foreign body.

Under *constitutional factors* we have to consider firstly, pathological states of the blood, the more important being hæmophilia, various anæmias—especially pernicious anæmia, leukæmia, lymphadenoma, splenic anæmia, infantile and adult; malaria, purpura, scurvy, and toxic jaundice. Another constitutional factor is associated with increased blood pressure or vascular congestion, either organic or temporary. Of the organic type, we get cardiac affections, particularly those causing engorgement of the right side of the heart with back pressure, cirrhosis of the liver, chronic renal disease, bronchitis, emphysema, and whooping-cough. Of the temporary causes the chief are: violent physical exercise, the epistaxis of puberty, and of the menopause. Epistaxis also occurs as a symptom in the early stages of certain acute infective diseases, such as typhoid, scarlet fever, influenza, acute rheumatism, diphtheria, measles, and German measles. It is also seen in rarefied air, as in mountaineering and aviation.

Local Treatment.

The treatment must be considered with regard to the cause. Where this is a constitutional one dependent on an increased blood pressure, it should be recognised that such bleeding is at first distinctly beneficial and may avert a cerebral hæmorrhage. Where, however, the bleeding becomes excessive or where there is no constitutional cause, in the first instance, certain household remedies may be applied—such as pinching the nostrils so as to press the alæ tight against the septum; this will stop the bleeding in a large percentage of such cases. Cold ice-swabs can be applied to the nose and the nape of the neck, and the feet placed in hot water, the patient being in a sitting position. These failing, the nose must be cleared of all blood-clot in order to ascertain the exact bleeding-point. A good light is necessary, either a frontal mirror to reflect the rays of an electric bulb or lamp, or, better still, a good photophore run from an accumulator. The nose should be sprayed with a solution of cocaine combined with 1 in 1000 adrenalin, not only for allaying the pain and discomfort of the examination, but also for its vaso-constriction properties. Hydrogen peroxide, 10 volume strength and used cold in a spray, is useful for cleaning out the clot and is also a hæmostatic. Usually the bleeding spot can be seen in the "hæmorrhage area" indicated and can be stopped after cocainisation by applying a flat cautery point at a dull red heat, thus sealing off the mouth of the vessel; or, failing a cautery, the application of a 50 per cent. solution of nitrate of silver, or of pure carbolic acid, on a probe with a small mop of wool, is usually effective. Care should be taken that only a very little of the solution should be used on the mop—just enough to touch the bleeding-point. The older methods of inserting into the nares a plug of wool soaked in perchloride of iron, tannic acid, &c., are to be deprecated, owing to the spreading of the solution with consequent damage to the delicate ciliated epithelium of the mucous membrane.

Should these methods fail, or not be applicable, two chief alternatives remain: either to pack the nose with a half-inch gauze plugging soaked in 1 in 1000 adrenalin solution, or the insertion and inflation of a distensible bag such as Cooper Rose's or Howard's—of these bags the latter has the advantage of not perishing easily and so can be always kept handy for use. Howard's bag has an introducer and with this it is passed into the nasal cavity, keeping well along the floor until practically the whole length of the bag has been introduced; it is then distended with a small bellows and a tap on the tubing of the bag is turned to prevent the air from coming out. The bag fills the whole nasal cavity and so by pressure prevents the bleeding. In 24 hours this bag is removed by opening the tap and allowing it to collapse, when it can be easily withdrawn without any danger of restarting the bleeding. Plugging with gauze has the great disadvantage that its removal in 24 hours is apt to restart the bleeding. This can be partially obviated by using gauze impregnated with adrenalin and soaking just before insertion in liquid paraffin; it is then not so apt to stick on removal.

Internal Remedies.

A hypodermic of morphia gr. $\frac{1}{6}$–$\frac{1}{4}$ has a marked beneficial effect, both as a hæmostatic and in quietening an excited and alarmed patient. Various hæmostatic sera for injection have been put on the market, but my experience has not been encouraging, and in a few cases disagreeable subsequent symptoms followed their use. The internal administration of calcium lactate has been advocated; all that can be said is that it does no harm and can be tried for the repeated hæmorrhages in the various blood conditions. Where pathological conditions exist on which the hæmorrhage is dependent these naturally have to be dealt with in order to avoid recurring attacks.

IMPERIAL CANCER RESEARCH FUND: SCIENTIFIC REPORT.[1]

THE Eighth Scientific Report issued by the Imperial Cancer Research Fund under the direction of the Royal Colleges consists of four reprints of papers published in various journals since the issue of the Seventh Scientific Report in 1921, and six hitherto unpublished communications. Dr. J. A. Murray, in a brief preface, points out that these papers fall into two groups. Those at the beginning of the Report deal with the behaviour and character of cells already cancerous. Dr. B. R. G. Russell's two papers on Carbohydrate Metabolism of surviving Normal Tissues and Tumours, Dr. W. Cramer's discussion of the Relation of Vitamin Deficiency to the Growth of Cancer, and Dr. A. H. Drew's two papers on Tissue Culture come into this category. Those in the second group deal with the induction of cancer: the changes which cells undergo in becoming cancerous. Dr. A. M. Begg's descriptive account of Infiltration in Tar Carcinoma heads this part and partakes partly of both categories. Dr. Russell's work on the Production of Tar Sarcoma and Dr. Murray's paper on Primary and Secondary Resistance to the Induction of Cancer are followed by Dr. A. Scott's monograph on Paraffin Dermatoses and Cancer in the Operatives of the Scottish Shale Oil Industry. The last-named paper is included in the Report because it embodies the results of an unintentional experiment on a large scale on the human subject, carefully observed and recorded over a long period. As the same favourable conjunction of material and observer is unlikely to recur it was deemed advisable to make an adequate permanent record of it widely available. Since the papers reprinted from various journals were for the most part noticed in our columns on their appearance, we propose to deal here only with some of those papers in a most comprehensive Report which are now issued for the first time. Among the most important of these is the survey by Dr. Cramer of

Dietary Deficiencies and the Growth of Cancer.

He points out that vitamins are often described as "growth substances" or "growth factors," because in their absence from the food a young animal such as a rat either completely ceases to increase in weight and size or the increase is retarded. If vitamins are essential for growth, as is so generally supposed, the possibility suggests itself of controlling the growth of cancerous cells by dietetic means in this way. Experiments along these lines, carried out by Drummond in 1916, yielded entirely negative results, and Dr. Cramer's observations confirm Drummond's results and show that they are applicable to all kinds of cancerous cells. If the premise is true that vitamins are necessary for the growth of normal cells, then there appears to be disclosed a fundamental biological difference between the factors controlling the growth of normal cells and of cancerous cells. Dr. Cramer's investigations, however, have led him to reject the generally accepted premise that the life and growth of normal cells are dependent on the presence of vitamins, so that in this respect no fundamental difference exists between normal cells and cancer cells.

The effect of vitamin deficiencies on tumour growth was studied in mice and in rats. In no case did a growing tumour recede, nor was its growth even arrested, as a result of withholding either vitamin A or B from the food either separately or jointly. The contrast between the effect of the vitamin deficiency on the tumour and on the animal itself was very remarkable. Tests were also undertaken to ascertain whether an abundant supply of vitamins has a stimulating effect on the rate of tumour growth when compared with a restricted supply of vitamins. The effect of adding an abundant supply of vitamins to the ordinary laboratory diet in the form of cod-liver oil and marmite is to produce a much more rapid increase in weight and stature of the host without in any way affecting the rate of tumour growth. There is therefore no reason to fear that an abundant supply of vitamins might be harmful to patients suffering from cancer. Since the continued growth of cancer cells in animals suffering themselves from vitamin deficiencies might be accounted for by postulating for cancer cells either an increased affinity for vitamins or the power to synthetise vitamins, experiments were performed to test this possibility, but no support for these theories could be obtained. It therefore appeared necessary to test the correctness of the premise that vitamins are necessary for the life and growth of every cell and to study the mode of action of vitamins, and this investigation was undertaken by Dr. Cramer with the collaboration of Dr. A. H. Drew and of Dr. J. C. Mottram of the Radium Institute. The results, published in THE LANCET and elsewhere, show that the fact that the life of a highly differentiated animal is dependent on the presence of vitamins in the food does not necessarily imply that vitamins are necessary for the life of all the cells of such an animal. A similar objection is raised against the deduction that vitamins are essential for "growth." The expression "growth" is popularly used to denote the increase in size of a young highly differentiated organism after birth. It is well known that anything that interferes with the general health of a young animal will retard its "growth" as measured by its increase in size and weight. One may therefore use the regular increase in weight or stature as an indication of the general good health of a young animal. But to interpret any deviation from the normal as indicating the absence of some factor essential for growth generally is not admissible. There is, therefore, a considerable gap between the experimentally observed facts and the generalisation, which has been drawn from them, that every cell requires vitamins for its life and growth. If all cells were dependent on vitamins one would expect a condition of functional decline or structural atrophy affecting all the cells. But the atrophy affects very specifically certain tissues or groups of cells, and what is more, deficiency in one vitamin affects one specific tissue, deficiency in another vitamin affects an entirely different group of cells.

The evidence is even more conclusive when we take the isolated cells of such a highly differentiated organism. Dr. Drew has been able to analyse the factors which are essential for the life and for the growth of the isolated cells of a rat. These factors cannot be replaced by vitamins. Moreover, one of these factors is very thermolabile, being destroyed by heating to 60° C. for 30 minutes. The other factor is set free or formed by normal living cells as the result of damaging them. In all these respects these factors differ from vitamins.

The Effect of a Deficiency in Specific Amino-Acids on the Growth of Cancer.

It seemed of interest to study in comparison with vitamin deficiencies the effect of a deficiency in the diet of a well-defined chemical substance which is known to be essential for the life of highly differentiated animals as a whole. Hopkins and Willcock showed in 1907 that the amino-acid tryptophane cannot be synthetised by the organism, but must be supplied in the food if an animal is to grow and to live. The total amount of tryptophane present in maize meal is very small and was proved by preliminary experiments inadequate to support the life of a rat. The dietary was identical with the basal ration given in the vitamin experiments, except that the casein was replaced by maize meal. The general effects produced by a tryptophane deficient diet in young rats are remarkably similar in many respects to those occurring in the absence of the vitamin B. But there are features which distinguish the later stages of this amino-acid deficiency quite sharply from the vitamin B deficiency. The hair falls out in patches after six or seven weeks of this diet, and after another eight to ten days there is an extensive œdematous condition extending over parts of the trunk and stretching the skin. Of the organs the most striking naked-eye change is presented by the pancreas, which is completely disorganised by œdema. Microscopic examination has only been made so far of the thyroid and adrenal glands. The adrenal gland shows no very distinct alteration; a very profound change was found, however, in the thyroid gland, and the morphological appearances of the thyroid gland taken in conjunction with the condition of the fur indicate that the absence of tryptophane produces a condition of hypothyroidism. There is, therefore, a very specific relation between this amino-acid deficiency and certain endocrine organs. The view that the thyroid needs a supply of tryptophane for its specific functional activity is confirmed by the fact that according to Kendall the active principle of the thyroid, thyroxin, is an iodine derivative of tryptophane. The same specific relation appears to exist between tryptophane and the pancreas. These specific lesions resulting from tryptophane deficiency have apparently not been noted before. The general significance of these observations is not considered in the report, the object of the experiment having been to establish the fact that although most, if not all, cells of the body require tryptophane for the building up of their protoplasm, there is a specific demand for tryptophane on the part of certain cells, and as the result of an inadequate supply specific lesions with specific symptoms.

---

[1] Taylor and Francis, Red Lion Court, Fleet-street, E.C. 1923. Pp. 42. Price 20s.

If a tumour is transplanted into a rat which has been kept for several weeks on a trytophane-free diet, it takes and grows progressively, although not quite as rapidly as in normal rats. The rats were kept for three weeks on the special diet, so that a distinct deficiency in tryptophane was present, as shown by the loss of weight and subnormal temperature, by the time the tumour cells were implanted into the animal. The active proliferation of the tumour cells under these conditions is a very striking phenomenon. Another remarkable feature of these experiments was that the presence of the tumour aggravated the deficiency so far as the host was concerned, by accelerating the onset of the specific symptoms and the final decline of the host. The slight retardation in the rate of tumour growth which does occur is adequately accounted for by the severe pathological lesions which develop progressively in the organism of the host carrying the tumour. That progressive growth does occur under such conditions is more remarkable than that the rate of growth is not as rapid as in a normal host. The presence of a mass of rapidly growing tumour cells which are known to require a supply of tryptophane for the building up of new cells reveals a clear and significant difference between the deficiency of such a substance and the deficiency of vitamins. As we have shown, the presence of a tumour does not accelerate the onset of the symptoms due to the vitamin deficiency. The results of the tryptophane deficiency confirmed the conclusion that vitamins are not required by either normal or cancerous cells for their growth or their life.

Dr. Cramer adds some general conclusions on the elation of diet to cancer and on the biochemical mechanism of growth, which should receive careful tudy.

Dr. A. M. Begg gives an account of a histological tudy of the

Dissemination of Tar-cancer in Mice,

specially of the local spread of epitheliomatous growths produced by repeated application of coal-ar or extracts of coal-tar to the skin of mice; in ll, 140 tumours were available for this purpose. The author demonstrates that dissemination takes place by way of lymphatics, blood-vessels, and also along nerve trunks; this last route is of interest from many points of view, and is fully discussed.

Dr. B. R. G. Russell describes an

Experimental Osteo-sarcoma of Rat.

This tumour occurred in an elderly female rat, one of the series of 40 animals which had been inoculated subcutaneously with tar once a week for 12 months. The inoculations ceased after this period, but the four survivors were kept under observation and examined at intervals. Six months later, the single rat remaining alive was found to have a hard but apparently tender nodule situated beneath the skin of the right groin, about the site where the tar inoculations had been done. During the next three weeks the tumour grew steadily and fairly rapidly, more than trebling its bulk in this period. Excision of the growth was performed under ether anæsthesia. Microscopically the tumour is a polymorphic-celled sarcoma containing bony particles and osteoid tissue. It is readily transplantable into normal rats, transplantation being usually successful in 60 or 80 per cent. of the cases; the daughter tumours grow rapidly, but many regress and disappear entirely after three or four weeks' growth. From the point of view of the experimental production of cancer, this case is of special interest because of the long interval, five and a half months, elapsing between the cessation of tarring and the detection of a growth.

Dr. J. A. Murray discusses

Primary and Secondary Resistance to the Induction of Cancer.

Primary Resistance.—The researches on experimental carcinogenesis of the past ten years have familiarised pathologists with the constancy with which a continuation of the effective stimulation over a considerable time is essential to successful induction of cancer. This feature of the course of such experiments harmonises with the chronic character of the irritations which clinical experience of the disease in man and animals has shown to be nearly universal in those forms of the disease where such a nexus can be inferred. Taken in conjunction with the histological identity of the lesions, it gives us reasonable assurance of the fundamental identity of the processes involved in cancer as it occurs naturally and under experiment. The application of tar is the only method used to produce cancer in these experiments. The length of time which elapses from the beginning of tarring till real autonomous growth sets in shows great variation even in animals of the same species. In the mouse this interval may be as short as three months, or as much as 18 months, and in one experiment a mouse remained free from growth, although tar had been applied to the same area twice weekly for more than 18 months. The majority of mice, however, develop skin carcinomata within six to nine months of tarring applied twice weekly. The extent of the area painted appears to have little influence. Very similar results have been obtained by painting the whole dorsal surface of the animal (Deelman), or an area of a square centimetre (Fibiger and Bang), or less (Murray and Woglom). The frequency of the application, as might be expected, affects both the rapidity of induction and the percentage of success. Even a reduction from twice to once weekly prolongs considerably the interval necessary to produce cancer in mice. Deelman, by scarifying the skin of mice before treating them with tar, shortened the time necessary to produce cancer by roughly a quarter; this observation is in agreement with the work of Drew by the method of tissue culture on the mechanism of repair.

In the past one has been accustomed to regard the preparatory period of chronic irritation which precedes the development of cancer as occupied in a gradual cumulative removal of resistance on the part of the organism to the unrestricted powers of growth of its constituent cells. It is more likely that in cancer the cell acquires new properties, exploitations of the normal cell activities, but acting in a new way with disastrous consequences to the organism. Two other features of the development of cancer under experimental conditions bear on this conception of the secondary character of the neoplastic transformation. The first is the discrete focal character of the process. Growth begins in isolated, usually minute, areas and not diffusely throughout the whole zone of application of tar. The second is the existence of a latent period, very little affected by continuation of the irritant, as indicated by Deelman's work, and emerging clearly from the deliberate experiments of Leitch and of Bang. These authors, working independently, stopped the applications after two, three, or more months in animals which had shown no proliferative changes or only slight hyperplasias, and found cancer appearing after a further interval at the treated site. In several instances the local hyperplasia had regressed and the skin had become smooth, and the new growth started in the otherwise normal but hairless area.

Secondary Resistance to Cancer Production.—The strict localisation of experimental tar-cancer to the area painted would lead one to expect that subsequent tarring of another area remote from the first would again result in the production of a fresh primary growth at the new site. Experiments of this kind frequently end prematurely by the death of the animal from intercurrent disease or from metastasis in internal organs from the first primary growth. For this reason, although these attempts have been carried out for more than two years, in more than 50 mice, in which experimental tar-cancer had been produced, in only three was the second tarring at all commensurate in duration with the first. In none of these mice was there any indication of proliferative changes at the second site. Taken by themselves, these observations are without significance, except incidentally, for the doubt they throw on the presumed predisposing action of age as increasing the liability to cancer, if no other factor be assumed to operate. The result of a similar trial in mice with spontaneous mammary cancer, however, increases the probability that these negative results are not fortuitous, but due to a real insusceptibility of the animals to the carcinogenetic action of tar. The tarring of 14 mice in which spontaneous mammary carcinoma had been removed by operation resulted in the growth of a tumour in only one animal.

Another experiment was carried out to see how long the first stimulation must precede the second in order to prevent the development of cancer from the latter. Only nine mice out of 50 used survived long enough to develop tumours. They had been painted twice weekly on the left shoulder with the ethereal extract of tar with which most of these experiments have been performed. Seven weeks after the beginning of the tarring, applications were begun on the right flank, unaltered hairy skin intervening between the two areas. In two mice carcinomata have developed at both sites and practically simultaneously. In four no growth has been produced at the second site, although in all but one which died early, tarring has been kept up for a period, as long as, or longer, than was necessary in the first instance. In three mice retarded development of a tumour was obtained at the second site.

Some of the peculiarities in the results of another experiment, planned originally to show the relative carcinogenic efficacy of the alcohol-soluble, and of the ether-soluble fractions of tar in comparison with the unaltered whole-tar, bear out this conclusion of a general systemic effect of the development of one primary growth, on the liability of the animal to develop another primary growth. The experiments show that the induction of a fresh primary growth after a first has been definitely established, meets with a very intense resistance, whether the first tumour be of the same parent tissue or another. The nature of this secondary refractoriness to the induction of cancer is obscure. It is not a resistance to growth, but is, apparently, an inability to react with cancerous proliferation to procedures which initiate it with certainty in normal animals.

The nature of this refractory state must be the subject of further investigation. The rarity of multiple malignant new growths in the same individual finds a rational explanation by it. Its greatest interest and importance, however, lies in the indication it gives of a systemic constitutional change in the organism in which cancer has developed, a change which, if it could be recognised with certainty and rapidity, would enable us to recognise cancer in its earliest stages, and could we produce it without initiating new growth, would place in our hands a rational means of prevention.

The last paper in the report is by Dr. Alexander Scott, Medical Examiner of Paraffin Workers for Scottish Oils, Ltd., on the

Occupation Dermatoses of the Paraffin Workers of the Scottish Shale Oil Industry.

This paper, which is illustrated by excellent photographs, is based on the experience of over 24 years' continuous practice in the centre of the Scottish Shale Oil Industry, and on the results obtained during the past four years in carrying out routine examinations at intervals of three months of every workman employed in the paraffin departments of the various works in which the refining of paraffin is carried out. Those employed in the paraffin departments suffer from various well-defined skin lesions, due entirely to their working among and handling oily paraffin in several of the stages of the process of refining. These "occupation dermatoses" occur in approximately 50 per cent. of the workmen engaged in refining paraffin; the lesions appear in a few weeks or months after beginning work in the paraffin departments, and persist to a greater or less extent throughout the length of employment as paraffin workers; they disappear (at least the less chronic types) in a short time after ceasing work among paraffin.

Occupation Dermatoses.—The skin lesions due to contact with oily paraffin in a crude or semi-refined state may be described as conforming to the following types, of which one only or several may be found on the same individual:—

Occupation Comedones.—The comedones occur in parts exposed to contact with paraffin products, especially over the flexures of elbows, posterior aspects of elbows, upper aspects of shoulder-joints, and occasionally over the knees. Their origin is purely mechanical, being due to obstruction of the sebaceous ducts with semi-solid paraffin substances, or to thickening of the superficial layers of the epidermis, causing obstruction of ducts.

Folliculitis—Peri-folliculitis—Follicular Dermatitis.—This is one of the most prevalent forms of skin lesion occurring among paraffin workers, and consists of destruction of the hairs and hair follicles as the result of a mild inflammatory reaction set up by the action of shale oils. The follicles become somewhat dilated and are filled with epithelial debris and dirt, so that they appear as closely grouped clusters of black points over the parts affected.

Dermatitis Pustularis.—Two types have been observed: (*a*) one in which the condition is characterised by the appearance of numerous small pustules over the anterior aspect of the body and limbs; and (*b*) one in which the pustular eruption is due to the breaking down of the typical papule, which is the most prevalent form of occupational eruption.

Papular Dermatitis—Erythema Papulare.—This is by far the most common type of skin lesion met with among the paraffin workers of the Scottish shale oil industry, between 40 and 50 per cent. of the workers being affected. It consists of an eruption of small rounded elevations of a reddish colour, varying in size from that of a small peppercorn to that of a small pea.

Erythema Simplex.—This consists of a mild hyperæmia in which the redness is distributed uniformly over the forearms. The first appearance is a slight blush, followed by a greater degree of redness, which in the early stages disappears on pressure, to reappear when pressure is withdrawn.

Dermatitis Erythematosa.—This is essentially a dermatitis venenata of a subacute or chronic type, due to the irritant action of semi-refined paraffin on the tissues of the skin over a lengthened period, for years in practically every instance. It represents a further extension of erythema in which the congestion gradually merges into a chronic inflammation of the various layers of the epidermis and cutis vera, followed by induration, and, in the most advanced stages, by partial or complete destruction of small areas of the skin in the affected parts. The early appearances are first seen on workmen after continuous contact with paraffin substances for seven or eight years. The indurative stages become more pronounced as the periods of employment get longer. There is frequently a tendency to the formation of small, flat, scaly warts, usually oval or circular in shape, and a very important feature of chronic paraffin dermatitis, once the "warty stage" has been reached, is that the tendency towards the formation of epithelial hyperplasias may continue long after workmen have been removed from contact with paraffin irritants.

Epithelioma (*Paraffin Workers' Cancer*).—Epitheliomata as seen among the paraffin workers of the Scottish oil industry may be defined as epithelial growths followed by ulceration and necrosis of tissue, having their origin in the epithelial layers of warts or papules. This condition occurs in workmen about or over middle life, who have been paraffin workers for long periods—20 years or more. They usually arise from warts due to chronic dermatitis or the indurated papules already described, and therefore usually coexist with an advanced dermatitis erythematosa in which wartiness is a prominent feature, or with indurated papules of a simple nature. The usual appearance is that of a gradually growing epithelioma in the midst of a chronic indurated dermatitis with numerous simple warts or indurated warty papules, only one of which has become malignant. More than one epithelioma at one time seldom occurs on the same individual, though it is not uncommon for the same workman to have different growths at various times over a period of years. The warts or papules from which this condition arises have, as a rule, been present for many years in a benign form until the epithelial covering begins to proliferate more rapidly, with increasing growth of the primary lesion, until the characters of malignancy develop. Clinically, the epitheliomatous growth, as occurring in the Scottish oil trade, differs in no respect from that generally described in text-books, while microscopically it shows the same proliferation of epithelial cells forming cell-nests, with infiltration of the surrounding and deeper structures. The malignancy for a long time is not great, and the lymphatic glands do not become involved till a late stage; but this varies according to the situation, the glands being involved earlier when the lesion is situated on the scrotum than when the site is on the arm or forearm. The most common situations are on the back of the hands, lower third of forearm, and scrotum. It has been seen on the face at the outer and inner angles of the eyelids, the features of rodent ulcer being sometimes assumed. A point of importance is that, while the various forms of dermatitis and other skin lesions described are only got among the actual workers in or about the paraffin departments, cases of epithelioma have in the past been more prevalent among workmen in other parts of the various oil works, and under conditions in which there is not necessarily prolonged contact with or handling of oil, in any of the stages from the crude to the semi-refined and ultimate products. It has occurred in retortmen, labourers, and stillmen.

In all, 65 cases of paraffin epithelioma have occurred during the 22 years prior to Dec. 31st, 1921, and as far as possible the differentiation between paraffin pressmen (green shed workers) has been made, though it may be that some of those designated oil workers and labourers may actually have been paraffin shed workmen. In the oil works comprised under Scottish Oils, Ltd., there have been employed approximately 5000 workmen annually for many years, this number including oil workers, labourers, retortmen, and all forms of labour necessary in the distillation of shale and the refining of its products. It will thus be apparent that the cancer incidence is not high, being approximately 1½ per cent. in 22 years, or under 0·1 per cent. per annum.

Discussing the influence of the various constituents of oil shale in the production of dermatoses, the author concludes there is no sufficient evidence to ncriminate any particular one, though he thinks it s possible that sulphur compounds may be the exciting cause, and he summarises the position thus: The various forms of dermatitis, whether papular, pustular, or erythematous, found among paraffin workers are due to direct contact with some chemical substance which, by the formation of warts and indurated growths, acts as a predisposing cause of epithelioma; the determining factor or xciting cause of epitheliomatous degeneration is, in common with all other forms of cancer, unknown. Length of service and personal idiosyncrasy are important predisposing causes. The paper contains a useful bibliography and much valuable information about the conditions obtaining in the Scottish shale oil industry.

SOME COMMON MOUNTAIN AILMENTS, AND HOW TO COMBAT THEM.

BY BERNARD HUDSON, M.D. CAMB., M.R.C.P. LOND.

I HAVE been asked to write a few notes for the benefit of those numerous people, who will be shortly spending their vacations in the Swiss Alpine resorts, as to how certain unpleasant complications of a Swiss holiday may be counteracted.

Mountain Sickness.

To take first what is usually known as mountain sickness, it should be mentioned, at the outset, that true mountain sickness does not occur until very high altitudes are reached. An interesting account of mountain sickness, and the sensations experienced at great altitudes—for example, 8000 to 20,000 feet—will be found in "Travels Amongst the Great Andes of the Equator," by Edward Whymper, where the effects of very high altitudes (and consequently low pressures) are carefully analysed as regards pulse, body temperature, breathing capacity, fatigue, and general sensations. What we are concerned with here, however, are the usual feelings of discomfort experienced by some people in ascending to a moderate altitude, and these are due to want of acclimatisation. As Turban has long insisted, everyone who comes up out of the lowlands into the high mountains has to go through a process of acclimatisation, even though he may not be aware that it is taking place. The following points should be remembered. As one ascends, the barometric pressure falls, and corresponding with the lower barometric pressure there is a fall in temperature. The humidity of the air, also, is much less, and the upper layers are very dry. Owing to the absence of water vapour, dust, smoke, and micro-organisms, the heat rays of the sun pass much more freely at high altitudes, and are very much more active; this is also the case with the light rays and the chemical rays. The radio-activity of the sun is greatest when the winter snow has fallen.

Upon the healthy person the general effects of altitude may be summed up as follows. The metabolism of the body is increased, the respirations and the pulse-rate are quickened, and the body temperature tends to be slightly higher than at sea-level; in other words, even at a moderate altitude, such as 4000 to 5000 feet, the usual height of a mountain resort, the rate of living is higher. Another point is that at sea-level the normal red blood-count is about 5 million corpuscles per cubic millimetre, and the percentage of hæmoglobin about 90; at an altitude of about 5000 feet, the blood in order to compensate for the diminished tension of oxygen in the air becomes richer in both red cells and hæmoglobin, the average red count at such an altitude being 7 million red cells per cubic millimetre, the hæmoglobin 100 per cent. or even more.

Thus, it will be understood that in order to get used to a high altitude the bodily functions have to become somewhat modified, and for this to be established a little time is required, varying from a few days for the ordinary healthy person to three or four weeks for those with less responsive power, or those who are definitely ill. Until the person is acclimatised there is a liability to feel a little discomfort; for instance, shortness of breath after exertion, palpitation, a feeling of oppression at night, sleeplessness, headache, and general malaise.

Persons, therefore, going out to Switzerland for strenuous winter sports, such as ski-ing, should take things somewhat easy to start with, and gradually accustom themselves to the altered conditions. To go for long expeditions directly on arrival is foolish, and is looking for certain trouble. For a person of nervous temperament to do so may imperil the entire advantage of the holiday.

Sun-burn.

Bad sun-burn is not common in mid-winter, but it is a real danger to be reckoned with from February onwards. Sun-burn depends upon various factors, of which altitude is the most important; the higher one goes the more likely one is to get sun-burnt. New snow is more effective in producing this than old snow. On the unprotected, unpigmented, and unprepared skin of persons coming out from England, long exposures to the hot Alpine sun, combined with the glare from the snow, can cause very severe burns. There may be produced definite toxic symptoms and fever. The most simple means of preventing this is to grease the face; for this purpose cocoa-butter is good, and two other preparations, both of which are excellent protectives and can be obtained in Switzerland, are Secheyé cream and anti-lux.

Snow Blindness.

Snow blindness, like sun-burn, is more likely to occur with new snow than with old snow, and at higher altitudes rather than at lower ones. The eyes become very sensitive to light, and the lids may become puffy and cracked, and may be glued together with dried secretion and refuse to open. There is much lacrymation. The pain is acute, and the whole condition is one of extreme discomfort. It can, however, be easily guarded against by the simple measure of wearing the amber-coloured glasses suggested by the late Sir William Crookes.

Montana, Valais, Suisse.

HOLLAND.

(FROM OUR OWN CORRESPONDENT.)

The Medical Profession in Holland.

IN Holland there are altogether about 3500 medical practitioners—i.e., only 1 per 2000 inhabitants. As of this number only about 2700 are general practitioners, the remainder being specialists and medical "officials"—i.e., medical officers of health, military surgeons, &c.—it might appear from an English or American point of view that the Dutch general practitioner was overburdened with work, and that medical care leaves something to be desired. Such, however, is not the case, for it must be remembered that Holland is one of the most densely populated countries of Europe, and that the roads in this "flat" land are, generally speaking, good. Moreover, the Dutch population is fairly healthy, and people make relatively few calls on the doctor. Also medical fees are low, and a fairly large practice is required to produce an adequate yearly income. In general, a gross income of £1000 per annum is looked upon as an enviable one. The majority of general practitioners cannot command that figure, but there are, of course, exceptions. The ranks of the specialists are, as elsewhere, limited; and perhaps the most fortunate members of the profession are the clinical professors of medicine. The Government salary of about £750 to a medical professor is not in itself sufficient for a scientific worker without other source of income, but the majority of clinical professors are very much in demand as consultants, and may thus manage to double their income. For a consultation in his office a professor rarely gets more than £1, while the fee for an operation may be as high as £100 to £250. The bulk of operations are performed for £50 or less. The fees of general practitioners vary between 1*s.* 6*d.* and 10*s.* per visit; in the country a surcharge is made for distance and loss of time. The specialists' fees amount to about twice the general practitioners' fees.

The Panel Doctor in Holland.

In view of the recent panel crisis in England it might be of interest to give some data regarding medical fees in respect of sick-clubs in Holland. The old "Battle of the Clubs" has been brought to a decisive issue largely through the activity of the Dutch Medical Association, and a better understanding has been reached between the friendly societies and the doctors. Nevertheless, there still exists, here and there, something of the methods which Sir Clifford Allbutt stigmatised as "the obsolete practice of tongue, pulse, and bottle." The medical benefit is administered entirely on the capitation system. A draft Bill of a National Health Insurance Act was introduced into Parliament three years ago, but the changes it proposed were too far-reaching, and it was accordingly shelved. When this Bill was under discussion in medical circles a capitation fee of 7*s.* was proposed, in the first instance as a minimum, and finally as a maximum. At present the average fee paid by the sick-clubs in Holland amounts to about 5*s.* per head. The following table gives the itemised expenditure in 1922 of two of the largest Dutch sick-clubs, each comprising about 100,000 members. The one functions for the labouring classes of Amsterdam, the other for the miners in Limburg.

Money Disbursed per Head for Each Member of the Club.

Items.	Limburg.			Amsterdam.	
	s.	d.		s.	d.
Capitation fee, general practitioners ..	4	1	....	5	5
Medical specialist's services	1	2	....	1	2
Dentist's service	–	3	....	–	5
Various specialist services (e.g., X rays) ..	1	0	....	0	4
Capitation fee, dispensing chemists ..	2	10	....	3	3
Cost price medicines and surgical appliances	1	1	....	2	10
Costs of nursing in hospital	10	10	....	12	0
Transport cost of patients	0	3	....	0	1
Contribution to district nursing	0	2	....	—	
Fees to midwives	0	10	....	0	6
Costs of administration	1	0	....	1	8
Total	23	6	....	27	8

A study of the above table will show that the Dutch doctor has some cause to envy his English confrère in the matter of capitation fee.

Sodoku (Rat-bite Disease) in Holland.

Sodoku was first described by Miyake, and recent cases of this remarkable disease merit description, especially where they occur in countries in which the condition had not hitherto been observed. Altogether, six cases have now been described in Dutch literature (two in van Lookeren Campagne's dissertation, one by Hymans van den Bergh, one by Berckel, one by Cornelia de Lauge and L. K. Wolff, and now one by van Dijk). The earliest Dutch case is that of a man of 71 years, who has now been suffering from this disease for 20 years and who was diagnosed by Dr. Guldenarm after reading Miyake's publications. The latest case was recently described in the *Genees-kundige Gids* (the *Medical Guide*) by van Dijk (Rotterdam). A child became ill 14 days after it had been bitten during sleep by a rat. The bite was situated at the corner of the left eyelid, where two pairs of holes the size of a pin's head—caused by the rat-bite—were to be seen. In a fortnight's time an extensive red and hard œdematous infiltration round it extended to above the eyelid. In the throat region a little gland of the size of a bean could be felt, which was painful on pressure. There was no exanthema, temperature 39·9° C., pulse 140, leucocytosis (W.B.C.'s 15,000; polynuclear leucocytes, 85 per cent.; no eosinophilia). A little albumin was present in the urine, no sugar, much urobilin, Wassermann reaction negative. The fever fell slowly to normal in six days, to be followed by another attack (recurrent type). Each attack of fever was accompanied by exacerbation of local symptoms. Salvarsan was not without effect in this case, but it took three months before the patient was completely cured. The fact that the spirochæte of the sodoku type was not found was disappointing, but nevertheless, in this case the clinical diagnosis was convincing.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Suggestions for Organised Research.

A CONFERENCE of medical men from almost all parts of India was recently held in Calcutta to consider how research in diseases could be made more effective. Among the recommendations made is one for the appointment of an impartial committee of medical men selected from among the leading surgeons and physicians in the United Kingdom to suggest methods by which research work throughout India may be coördinated to the best advantage. It was felt that if such a committee were appointed in India, it would be difficult to avoid the influence of local prejudices. There is at present little coördination between the workers in the different Indian provinces engaged in studying causation and methods of checking or eradicating disease, and the labours of workers in one province are not available for guidance to workers in another.

Pasteur Institute for Calcutta.

India already possesses three Pasteur Institutes for the treatment of hydrophobia. These are all situated in the hills, at Kasauli (near Simla), at Shillong, in Assam, and at Coonoor, in Southern India. As, however, experiments of recent years have shown that the vaccine used in the treatment of hydrophobia can be kept in the Indian plains without any danger of deterioration if sufficient care is taken, a proposal is shortly to be presented to the Government of Bengal to establish a Pasteur Institute also at Calcutta in connexion with the Calcutta School of Tropical Medicine. Experts who have examined the proposal are of the opinion that there is no reason why the vaccine should not be manufactured in Calcutta. The technical processes and the maintenance of a small staff under the charge of a medical expert are not expected to cost more than what the local government pays as its contribution towards the maintenance of the Pasteur Institute at Shillong. The establishment of an institute in Calcutta will not only prove more economical to the Bengal Government, but it will also mean a considerable saving in time and money to the sufferers who have now to spend large sums of money in railway fares and for expenses in Shillong during the fortnight's stay while undergoing treatment. The mercantile community in Calcutta, it is understood, will strongly support the proposal.

BRITISH PROVIDENT ASSOCIATION FOR HOSPITAL AND ADDITIONAL SERVICES.

Sir Alan Anderson presided over a dinner at the Savoy Hotel on Dec. 17th for the purpose of making the objects of the Association more generally known. The Chairman was supported by other members of the Executive Council—namely, Dr. J. F. Gordon Dill, Captain J. M. Gordon Dill, Mr. W. McAdam Eccles, and the Hon. Sir Arthur Stanley. Lord Dawson was unable to be present.

The guests included Dr. H. B. Brackenbury, Mr. L. G. Brock, Mr. J. Courtney Buchanan, Dr. C. Buttar, Major Crawley, Mr. Ward Cook, Dr. Alfred Cox, Mr. T. Denman, Mr. F. B. Elliott, Sir William Hale-White, Mr. N. Bishop Harman, Sir Thomas Horder, Sir Robert Kindersley, Sir Walter Lawrence, Mr. H. Lesser, Colonel Levita, Mr. Cecil Lubbock, Sir Edward Marshall-Hall, Mr. R. Holland Martin, Dr. E. C. Morland, Mr. E. W. Morris, Sir Thomas Neill, the Hon. Cyril Ponsonby, Mr. J. F. P. Rawlinson, M.P., Lord Riddell, Lord Somerleyton, Mr. H. S. Souttar, Mr. H. J. Waring, Major Wernher, Dr. R. McNair Wilson, and the Representative of THE LANCET.

Mr. E. W. Morris, in proposing The Association, said that it would benefit the voluntary hospitals, the public, and the general practitioner. Voluntary hospitals originally founded as shelters for the sick poor had now become armouries for fighting disease, and the cost had crept up to £5 a week per bed. The new departments which had constantly to be added were not earning departments, and the hospitals had only four alternatives. They could go back to the £2 per bed standard by cutting off the new departments and reducing the nursing; they could close beds; they could be nationalised; or prospective patients could be asked to contribute small amounts when well to cover in whole or in part the cost of their treatment when ill. For the manual worker there had been founded a Hospital Saving Association which helped groups with an average health-rate to obtain definite hospital services. The British Provident Association was a similar institution intended to benefit the "black-coated poor," who, as a rule, had not been considered eligible for hospitals. Under the scheme of this Association the subscription varied from £1 1*s.* per annum for a single person to £1 11*s.* 6*d.* for a married couple and £2 2*s.* for a family. On the recommendation of the patient's own private doctor he would obtain the advantages of hospital research, and of special treatment such as massage, and he would be admitted to hospital on the recommendation of the consultant whom the general practitioner had called in. The Association would pay £3 3*s.* for a consultation and £4 per week to the hospital towards the patient's cost, or a similar amount to a selected nursing-home. Contributions would be made for surgical appliances, dental treatment, and dentures. Should home nursing be required, 1*s.* 6*d.* a visit would be paid, while radium treatment and an ambulance service were also available. The scheme would enable the general practitioner, especially in country districts, to fight disease with modern weapons.

Sir Alan Anderson, in reply, said the problem was a simple one. The hospitals were a great health factory and as they extended their expenses increased. There was an immense mass of people getting good wages who wanted to be kept in health and yet preserve their spirit of independence. The British Provident Association was really an assurance association to help these people. It was desired to secure the support of large city firms who would introduce the scheme to their staffs and would also take a share of the expenses, following the example of Sheffield, where he was told 96 per cent. of the large firms supported the Hospital Saving Association and paid a third of the full hospital cost to their men.

Sir Arthur Stanley, in proposing The Guests, paid a tribute to Dr. Gordon Gill for his initiative and ability. Lord Riddell, Sir Edward Marshall-Hall, and Mr. J. F. P. Rawlinson, M.P., replied.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. H. L. Page is placed on ret. list.

J. Wolstencroft and T. C. H. Neil to be Surg. Lts.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majs. to be Lt.-Cols: C. G. Thomson, vice Lt.-Col. A. L. Scott, ret. pay; Bt. Lt.-Col. A. McMunn, vice Lt.-Col. E. B. Knox, ret. pay.

Capt. F. P. Freeman retires, receiving a gratuity.

The undermentioned temp. Capts. relinquish their commns., and retain the rank of Capt.: E. A. Tozer and R. W. Shaw.

Capt. E. G. Foley retires, receiving a gratuity.

The undermentioned temp. Capts. relinquish their commns.: W. L. Hay, and is granted the rank of Maj.; J. A. Marsden, and retains the rank of Capt.

ROYAL AIR FORCE.

Flight Lt. (hon. Squadron Leader) J. N. MacDonald is granted the acting rank of Squadron Leader whilst so employed. Flight Lt. J. W. Harper is transferred to the Reserve Class D 2.

Maj. C. M. Rigby, R.A.M.C., and Capt. H. D. C. Rankin, R.A.M.C., have been appointed surgeons to H.E. the Commander-in-Chief in India.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The following table gives some of the principal health statistics for 1922 of a group of towns, differing much in circumstances and local government standing:—

Name of town.	Estimated population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality		Maternal mort. in childbirth.
							Legit.	Illegit.	
Chester	41,190	20·9	13·8	1·2	1·3	3·6	72	184	9·2
Oldham	148,300	19·3	15·8	1·3	1·2	3·9	100	177	2·8
Great Yarmouth	56,700	19·3	12·9	1·3	1·2	3·0	84	118	1·8
Walsall	99,890	25·4	12·9	1·5	1·0	3·4	94	120	3·5
Darlington ..	66,710	22·6	14·1	1·4	1·0	3·4	94	143	3·3
Nuneaton ..	43,401	24·4	9·8	1·1	0·8	2·1	(78)*		5·6
Dover	40,390	20·5	11·4	1·0	1·3	2·6	52	68	3·6
Llanelly	37,800	20·6	11·3	1·2	1·1	2·8	79	154	2·6
Macclesfield ..	32,886	18·7	15·3	1·2	1·5	3·0	66	75	1·6

Chelmsford ..	20,990	17·9	11·2	0·8	1·5	2·0	38	182	0·0
Stretford ..	47,530	16·0	11·5	0·9	1·2	2·5	68	69	6·8
Weston-super-Mare	25,070	14·1	12·2	0·8	1·2	2·5	36	136	2·8

*Undivided infant mortality.

City of Chester.

Dr. D. Rennet reports that housing needs were not met by the 37 new houses provided, so that conditions are, if anything, worse than last year. The prospect is better at present, "but the limitations imposed by the labour and material available will not allow the rate of building to overtake the need for many years." Half of the pneumonia cases investigated were sleeping four or more in a room. There was only one notification of poliomyelitis and the experience of the orthopædic clinic is that this disease is overlooked during the feverish stage and only comes under notice when deformity is marked and cure long and difficult. Dr. Rennet deplores the fact that the Ministry have cut down by one-half the estimate for the cost of the treatment of non-pulmonary tuberculosis at the Chester Royal Infirmary and the Orthopædic Hospital, Oswestry. A sample of liquid eggs taken informally from a bulk supply was found to contain 82·6 gr. of boric acid per pound.

County Borough of Oldham.

Dr. J. B. Wilkinson says the principal item of the year's work has been preparatory to dealing with the larger of the two slum areas. Housing scarcity has prevented renovation and has enabled certain persons to profiteer by charging exorbitant rents for furnished rooms. Financial circumstances, owing to bad trade, have also prevented owners from undertaking improvements. The corporation completed 300 houses during the year and private builders 18. In response to a deputation of property owners, the Health Committee agreed to suspend the conversion of privies during the year. Dr. Wilkinson mentions that the permissible limit of black smoke from the chimneys of boiler furnaces is a liberal one, and that there were no prosecutions. He, however, tells us that the use of electricity for power is being extended, and he opines that this and the use of gas and smokeless fuel for heating "will enable future generations in Oldham to see the sun more frequently than the present one."

County Borough of Great Yarmouth.

Dr. A. N. Stevens draws special attention to the fact that 45 per cent. of the deaths of Yarmouth residents occurred at ages over 65 and 23 per cent. at ages over 75. All the dwelling houses, except 24, are supplied from the company's mains with water obtained from Ormesby Broad and the River Bure and subjected to sand filtration. There are still 24 wells, many of these "without doubt liable to pollution at times, but unless the samples for analysis happen to be taken at one of those times they cannot be dealt with." One would have thought, however, that if the surroundings of a well showed it to be liable to pollution it would be possible to get it closed. The maternity and child welfare report shows that of over 1000 infants visited 75 per cent. were breast-fed at the fourth month. An unusually high proportion of the births in Yarmouth are attended by medical men, about two-thirds in 1922.

County Borough of Walsall.

Owing to the death of Dr. H. Shore, the report is submitted by Dr. James A. M. Clark, acting medical officer of health and tuberculosis officer, who issues a serious warning as to the large number of unvaccinated children in the borough. Dr. Clark draws attention to the marked increase in the death-rate from pulmonary tuberculosis. The increase was most marked among females in the age-group 25–35 and also occurred amongst males in the age-group 35–45. Dr. Clark thinks the increase is due to the trade depression. Colloidal calcium has been tried extensively and appears to have given good results in children and in early cases in adults, but no very definite deductions can be drawn.

County Borough of Darlington.

Dr. S. G. Mostyn tells us that there is still great need for new houses, though private enterprise is beginning to supply the need. The work of the V.D. clinic has been greatly improved by the appointment in May of Dr. W. H. Brodie as a full-time officer. Dr. Brodie gives four days a week to this work and the remainder of his time to the school medical service. Six centres were opened during the year for the provision of free meals for school children; 295 children attended and 53,438 meals were supplied. The diet was approved by the school medical officer and the head of the domestic subjects centre. The school dentists ask for facilities for the administration of general anæsthetics and also suggest that they might give a lecture on the teeth, with the mothers present, in each school once a year.

Borough of Nuneaton.

Dr. K. E. Tapper submits very complete reports on the public health and school medical services, which, it is to be hoped, many of the residents will read. Situated on the Warwickshire coalfields, Nuneaton's chief industry is coal, textile industries coming next in importance, and providing female employment. There are, says Dr. Tapper, good provisions against distress in time of unemployment: a good water-supply (the new supply from Thornton reservoir near Leicester is nearing completion), good sewerage, an atmosphere free from gross smoke pollution, and no slums. Many of the births take place under adverse circumstances, and 44 of the 83 infant deaths occurred in the first four weeks of life. A maternity home and ante-natal clinic are needed. Midwives attend 94 per cent. of the births and are being asked, in return for a small fee, to do some ante-natal work. Dr. Tapper would like to see the control of the midwives under the authority responsible for child welfare. Amongst other needs mentioned are the conversion of privies (when the new water-supply is completed), the provision of a V.D. clinic in Nuneaton, and the extension of the school dental service (at present attention is almost restricted to the temporary teeth). Dr. Tapper has a good deal to say about personal hygiene, and instances the need for the education of the public in the right choice of food and the fact that some of the new council houses are suffering from indifferent tenants.

Borough of Dover.

Dr. A. B. McMaster refers to the high case-mortality from diphtheria. Five of the seven deaths were those of children admitted to hospital after the third day of the disease and some of these lives might have been saved by the use of antitoxin at an earlier stage of the disease. There is insufficient provision both for advanced and early cases of pulmonary tuberculosis, and the under-nourished pre-tuberculous child is an urgent problem. Owing to the continuance of unemployment there was a greater call on the milk scheme for the necessitous, 353 individuals being assisted, as compared with 294 in 1921. This assistance was, however, valuable in keeping down infant mortality.

Borough of Llanelly.

Dr. Laurence W. Pole reports that considerable improvements are being made in the milk-supply. The health committee have visited every cowshed and dairy in the town, and a most unsatisfactory state of affairs was found. Dr. Pole also comments unfavourably on the milk shops and methods of distribution, but anticipates that the report for 1923 will record a great improvement as the result of the operation of the Milk Act of 1922. Scavenging arrangements leave much to be desired. The regular removal of house refuse has been interfered with by the removal of trade refuse. Back lanes are universal, and it is a custom of old standing for householders to deposit their refuse in them. Strenuous action is needed to stop this objectionable practice. The number of houses now completed under the Government-assisted scheme is 462, but Dr. Pole estimates that 1000 more are needed to replace old property and deal with overcrowding. The need will be even greater when trade is normal. The work of the maternity and child welfare and school clinics has been hampered by unsatisfactory premises, but this will be remedied by the removal of both to specially adapted accommodation at the old town hall. Lessened unemployment has meant less call on the free milk scheme. A large number of school-children suffer from malnutrition and much of this is due, Dr. Pole thinks, to the wrong choice of food and the inadequate use of milk. Nothing is done for the children's teeth and the appointment of a school dentist is a very urgent need.

Borough of Macclesfield.

Dr. J. Hedley Marsh says the problem of housing gains yearly in importance and urgency. Wages are not high in Macclesfield, and Dr. Marsh would like to see houses provided, in rows if necessary, at a rental of 4*s*. or 5*s*. a week all included. "Until this is done the house shortage will continue," he says, "and, in trying to provide the ideal, we shall perpetuate the slums." Maternity and child welfare work has hitherto been chiefly in the hands of the voluntary workers of the Public Health Society with their headquarters at Hurdsfield House, and we gather from the report that the town council have just appointed their first two health visitors, who hold the dual qualifications of trained nurse and midwife. A considerable portion of the report is devoted to detailed bacterial analyses of the water-supply. The principal gathering ground of the town's water is in the uplands, beyond Langley, and is in some danger of pollution by farms. There is also a private supply with two small sand filters for houses in Hurdsfield-road, which Dr. Marsh would like to see abolished. The analyses refer to both and are put on record to let the committees concerned know the facts and to establish bacterial standards for comparison in future years. Dr. Marsh thinks the present pollution with intestinal bacteria may be eliminated by the acquisition of farms on the gathering grounds.

Borough of Gravesend.

Dr. C. D. Outred tells us that there is no provision for advanced tuberculosis and suggests that the town council might combine with adjoining districts to make such provision. A motor ambulance is also wanted. The question of overflowing cesspools has caused much expense and trouble. The corporation took the unusual course of deepening the cesspools at their own cost. The total cost of deepening 147 cesspools was £914. The previous cost of emptying these cesspools was £3880, and it is estimated that £2966 has been saved in the first year by the deepening operations. Twenty-two loads of chalk were removed at a cost of about £13 from one cesspool which cost £341 to empty in the previous 12 months, and it is possible that this cesspool will not require emptying for two or three years. The 96 houses erected by the corporation on the King's farm estate are all occupied and permission to sublet has been granted in 32 cases. Private enterprise has only erected six houses, and Dr. Outred thinks arrangements should be made with builders to erect 250 more houses on the corporation estate, to be let at a moderate rental. In the school report Dr. Outred refers at some length to the opposition of parents to minor operations and even to conservative dentistry. He hopes that the teachers may be able to give much assistance in wearing down this opposition.

Borough of Chelmsford.

Dr. Richard H. Vercoe submits the report for 1922, though Dr. William J. Cox was medical officer for the first six months and Dr. J. F. MacDonald acting medical officer for the second six months. The water-supply has to be cut off for part of the day in the summer months and the corporation is promoting a bill to obtain an additional supply from the Chelmer at Sandford Mill. Considerable progress has been made with the housing scheme, 176 houses having been completed during the year. In addition to this, private enterprise contributed 29 houses. In Chelmsford there are many houses in a bad state of repair. Dr. Vercoe mentions 130 as only fit for demolition, and 300 more which can only be kept habitable by constant repairs.

Urban District of Stretford.

Dr. William J. Heslop presents his thirty-sixth and farewell report and gives an interesting contrast between the conditions prevailing at the time of his appointment and now. The general death-rate has declined from about 15 to 11, the infant mortality-rate from about 160 to about 60, and the population has increased from 21,000 to 47,530. In 1887 there were many cellar dwellings and back-to-back houses, and the conveniences were mostly privy middens. All these have disappeared and many other sanitary improvements have been carried out.

Urban District of Weston-super-Mare.

Dr. John Wallace reports that there has been no unusual or excessive mortality during the year and that the infant mortality-rate was the lowest ever recorded. The new houses erected during the year numbered 59, 18 being municipal houses. The sanitary inspector states that apart from municipal houses there is no increase of accommodation for the working classes, and that owing to shortage of such houses proper renovation cannot be carried out and overcrowding cannot be dealt with. The abattoirs belonging to the council are the only slaughter-houses in the district and are in first-class condition. Humane killers are used for cattle and pigs.

PENALTY FOR IMPROPER CHARGES TO PANEL PATIENTS.—The result of the recent inquiry by the Ministry of Health at Tottington, Lancashire, respecting alleged improper charging of fees from insured persons by two local panel doctors was communicated to the Bury Insurance Committee on Dec. 11th. The communication states that the Ministry has decided that £1000 must be withheld from the supplementary grant payable to the Insurance Committee (Lancashire) in respect of medical benefit, and that this sum, together with the costs incurred by the committee in connexion with the inquiry, should be recovered from the practitioners by reduction from their remuneration or otherwise; arrangements should accordingly be made by the committee to recover the amount by instalments spread over a suitable period. The committee should also take steps to secure that a refund is made by the practitioners in all cases in which it is established to the satisfaction of the committee that fees have been irregularly charged by them.

Correspondence.

"Audi alteram partem."

ON SOME USES OF DIGITALIS.

To the Editor of THE LANCET.

SIR,—I am anxious to comment as briefly as possible on certain statements which Dr. G. A. Sutherland makes in THE LANCET of Dec. 8th under the above heading. Dr. Sutherland opens with a confession of unbelief; he says: "Claims are made that the contractile power of the heart muscle can be improved and increased by the direct action of drugs," and a few lines further he proceeds, "I am one of those humble unbelievers who has hitherto failed to find any drug which will act directly and beneficially on the cardiac power of contraction." It is a tremendous and sweeping pronouncement, and, as a firm believer in the power thus called in question, I would, in equal humility, make my profession of faith on the following grounds:—

In the first place, anatomy shows the heart to be richly supplied with nerve fibres, cerebrospinal and sympathetic, which bring it into touch with every part of the body. What do those fibres convey? Stimuli. What is asked of the heart in response? Contractile power, in quantity greater or less according to the circumstances which condition life; in other words, the power-output has to be adapted to the needs of the occasion. In physiologic life, then, stimuli play a recognised part, influencing directly the muscle fibres of the heart, now restraining, now reinforcing, and now regulating the contractions in their sequence. Let us now introduce the drug to the body; it is, ex hypothesi, possessed of properties capable of influencing the tissues; otherwise it would be inert and not a drug. Let us suppose an attack of fainting, the face is blanched, the pulse cannot be felt, and that we apply strong ammonia, secundum artem, to the nostrils. The colour returns to the face, the pulse to the wrist, the patient revives. In this case the powerful stimulus of the ammonia has been projected from the mucous membrane of the nasal cavities, viâ the central nervous system, upon the heart, and the heart has responded with a crescendo of systoles: it is a sequence as direct as the firing of a train of gunpowder issuing in the terminal explosion. A dose of brandy or of ammonia by the mouth, before the faintness had advanced quite so far, would have given like results, but in that case the projection of a stimulus from the mucous membrane of the stomach would have been followed by stimulant effects after absorption into the blood-stream.

Imagine next a case of intense collapse, the result of snake-bite, and that, according to the method of Prof. G. B. Halford, we inject the dose of ammonia directly into a vein; the success claimed for this method is most simply explained as a direct action upon the heart muscle as the drug passes through the chambers of the heart first, and subsequently is circulated through the coronary vessels. Advancing the argument a step further, let us perfuse the excised heart of a frog, by means of a Roy-apparatus, with an artificial blood, recording the systoles upon a revolving drum, and then introduce a suitable dose of an ammonium salt into the circulation; almost at once the stimulant effect is observed in the increased height and breadth of the series of systoles which now are traced. In this case the action could not be more direct, for all question of nerve influence is put aside, and if the ligature securing the heart to the perfusion cannula be properly placed in the auriculo-ventricular sulcus there remains only the ventricular walls *to be influenced*, and the medicated blood, within the ventricle, *to influence* them—the action could not be more direct nor the effect more unmistakable. To complete the evidence I would refer to Dr. Carl Bodon's paper, in THE LANCET of March 24th, on "The Intracardiac Injection of Adrenalin." In the directness of this method it comes nearest to the foregoing experiment, with this difference, of course, that the heart is here in situ with all its communications intact. The adrenalin was injected directly into the right ventricle, and though the full portraiture of systemic death was present before the dose was administered (unconsciousness, cessation of respiration and heart's action, death-like pallor, widely dilated pupils with loss of corneal reflexes, and involuntary voiding of stools and urine), within a few seconds the heart beat reappeared, and in less than half a minute became regular and effective. In this case, the circulation being to all intents and purposes at a standstill, what else but direct action of the adrenalin upon the inner surface of the right ventricle, the walls of which still held somatic life, can explain the result? Dr. Bodon's paper is based upon a material of 90 cases of intracardiac injection.

I pass to another point which I can only deal with very briefly: it concerns the type of case for which digitalis is suitable, which we are told has *now* been achieved (p. 1222, the italics are mine). The type is that which is most commonly spoken of as auricular fibrillation, and we are told that on this subject the teaching of Mackenzie "is now universally accepted," and that he has shown "that the benefits to be obtained from digitalis are more strikingly seen and more hopefully expected in cases of auricular fibrillation associated with rheumatic disease of the heart than in any other condition." I think there will be none to dispute that this is par excellence the type of case for digitalis, but have we had to wait till *now* for this knowledge or were we well acquainted with the type of case, which indicated digitalis, 40–50 years ago? Did we not know the case characterised by heart failure with rapid irregular action of the heart, the irregularity being both in time and force and yielding a very striking and easily recognised pulse; its common association with valvular disease, and very particularly with mitral disease, regurgitant, obstructive, or both the one and the other; its tendency to develop dropsy more or less widespread, up to a condition of almost complete waterlogging of the whole body; the frequent history of rheumatic antecedents, either in the patient or in the family history? Were not such cases pointed to as of the type calculated to convince the most hardened sceptic as to the value of drugs (as Dr. Ringer used to teach) in their astonishing response to digitalis? Did not Dr. G. W. Balfour lay down in most careful terms the rules which should guide the dosage of digitalis in this type of case? True, we did not know the state of flickering asystole of the auricle which obtained, but we knew its outcome, the delirium cordis, which was present, and we knew how to treat it effectively. The term auricular fibrillation tells us nothing as to the nature of the disorder which follows upon it; the symptoms declare this and the symptom-group sums up the *dis*-order; and the symptom-group we knew.

It is not doing justice to the facts of the case or to the memory of those observers in the past, who in respect of the use of digitalis have deserved so well of us, to withhold the expression of our indebtedness.

I am, Sir, yours faithfully,

Dec. 11th, 1923. HARRINGTON SAINSBURY.

THE PREVENTION OF BILHARZIASIS.

To the Editor of THE LANCET.

SIR,—So far as the commoner carriers of *Schistosomum hœmatobium* and *S. mansoni* are concerned, complete drying of pools for a few days at a time, as recommended by Prof. R. T. Leiper, is undoubtedly the most effective means at our disposal for eradicating these fresh-water snails. In the intense heat of the tropics, where evaporation is great, the animals soon die in their dry shell. But the menace of the mollusc in the marsh remains, for I have shown that in the moist heat of the Natal coast *Isidora tropica* from the Free State can live in the shade on a dry shelf for 48 hours and become active again when returned to fresh water. Moreover, by means of its operculum, the common intermediary host of *Schistosomum japonicum* is able to resist drying, the enclosed animal remaining moist within its shell for several weeks and emitting numerous cercariæ, as shown by W. W. Cort, as soon as it is returned to fresh water. Although I have never found schistosomes in an operculated shell in South Africa, the majority of the cercariæ with which they are infested being encysting forms, I have recently isolated them from a new family of fresh-water snail, *Barnupia*, and this mollusc is better able to resist drying than the majority of non-operculated shells, because of its very close attachment to reeds, whereby it also withstands the rush of a flooded river. The presence of living fresh-water molluscs in the lagoons that are formed at the mouth of Natal rivers does not alter the fact that the vast majority of intermediary hosts are quickly destroyed by sea-water, and the occasional salinity of lagoon water helps to keep them from accumulating in places where they might otherwise tend to breed in considerable numbers.

I am, Sir, yours faithfully,
F. G. CAWSTON, M.D. Cantab.
West-street, Durban, Nov. 23rd, 1923.

THE MEDICAL EXAMINATION OF MOTOR DRIVERS.

To the Editor of THE LANCET.

SIR,—Is it not now desirable that drivers of taxi-cabs and motor vehicles should be examined medically with respect to their ability to safely perform their duties? The possibility of serious accidents through the physical incapacity or ailments of a taxi-cab driver must have occurred to most people who have ever thought about the subject. I was much impressed some time ago when consulted by a taxi-driver who presented marked symptoms of affection of the nervous system. He admitted that it was no longer safe for him to drive a motor vehicle. He had a definite history of syphilis, and after careful examination I came to the conclusion that he was suffering from early general paralysis. His list of collisions with pedestrians (some serious) was already a long one, and I urged him to discontinue his occupation at once. I never saw him again, but he was still driving a taxi-cab a considerable time after he consulted me. When we consider the accidents that might happen through the driver of a motor vehicle having an epileptic fit, or an attack of petit mal, angina pectoris, or syncope, or cerebral or other severe internal hæmorrhage over and above those that might result from defective sight or hearing, it is strange that medical examination has not been required long ago.

Accidents cannot be prevented so long as motor vehicles are allowed to rush along our streets and roads at their present speed, and the increasing mortality from motor accidents is the price we pay, without protest, for the pleasure of this rate of travelling. But pedestrians at least deserve some consideration and protection, and medical examination of all who drive motor vehicles would do a little to diminish the number of accidents; it would also be a warning to the motor drivers and serve to remind them of the dangerous weapon in their hands.

Personally, I have no interest in such examinations except as a pedestrian.

I am, Sir, yours faithfully,
Dec. 14th, 1923. R. T. WILLIAMSON.

⁂ At a recent inquest a London coroner pointed out very forcibly that under present conditions anyone of the scheduled age, though blind, epileptic, or physically defective, can obtain for 5*s.* a licence to drive a motor vehicle. Plainly this risky state of things must be considered when the law affecting motorists is revised. And time presses.—ED. L.

Obituary.

PROF. ROBERT TIGERSTEDT.

Robert Tigerstedt, whose death we have briefly announced, was born in 1853 at Helsingfors. A Finn both by birth and sentiment, Tigerstedt studied at his native university, in Stockholm and in Leipzig. In 1876 he was appointed assistant in the physiological laboratory at Helsingfors, and in 1886 he became professor of physiology at Stockholm. In 1900, when Finland was going through difficult times politically, his patriotism impelled him to return to Helsingfors, where he was appointed professor of physiology, and where he remained until his death. He was one of the many distinguished physiologists who were pupils of Carl Ludwig. Tigerstedt's scientific work, which is very extensive, falls into three main groups—namely, the physiology of muscle and nerve, the physiology of the circulation, and metabolism. Some of his papers on muscle and nerve were translated into English for the "Biological Memoirs on the Physiology of Muscle and Nerve and the Electrical Organ," edited by Burdon Sanderson. At one time he took much interest in the alcohol question from the abstinence point of view. His early researches were on stimulation of muscle through its nerve, but perhaps he received earliest recognition through his lectures on the circulation of the blood which contained much new and historical matter, including the fundamental and classical researches of Stannius, of Rostock, on the heart. To later readers in this country and America his "Text-book of Human Physiology," translated from the third German edition by Prof. J. R. Murlin, of New York, in 1906, is the work by which he is best known. In later years he carried out researches on respiration and metabolism, and contributed monographs to Nagel's "Physiology," to Oppenheimer's technical treatise, and to the "Comparative Physiology" of Winterstein. His "Lehrbuch der Physiologie des Kreislaufs" is well-known as an authoritative statement on the circulation of the blood, and a second edition is in process of appearing. A recipient of many honorary degrees, he was a member of the Scientific Academies of Helsingfors, Upsala, Stockholm, Copenhagen, and Christiania, and in his sixtieth year a bronze medal was struck in his honour. Tigerstedt has been editor of the "Skandinavisches Archiv für Physiologie" since 1898. The forty-third volume of these archives was dedicated to him as a memorial on his seventieth birthday by his friends and pupils. At the last Physiological Congress before the war, in 1913, it was decided to hold the next Congress in Paris with Tigerstedt as its president. His judgment and his knowledge of physiology were greatly esteemed by his colleagues in all countries, and as a man he was loved by a large circle of friends.

GEORGE PESTER CHAPPEL, M.D. CAMB.

ON Dec. 15th the death occurred, at his residence, Altrincham, Cheshire, of Dr. G. P. Chappel, aged 55, one of the best known medical practitioners in the district. Death was due to pneumonia, after only a few days' illness. Dr. Chappel was the son of the late Canon Chappel, of Camborne, Cornwall. After studying at Cambridge and the London Hospital, he graduated at Cambridge M.B., B.Ch. in 1892 and M.D. in 1896. He was for a time house physician and later house surgeon to the late Sir Frederick Treves at the London Hospital, afterwards he practised at Tottenham, and came to Altrincham about 15 years ago. There, in addition to carrying on the work of a large private practice, he was medical officer of health for Bowdon and hon. physician to the Altrincham General Hospital. During the war Dr. Chappel, as Major in the R.A.M.C. (T.), served in Egypt, and later had charge of a large military hospital in London.

SYDNEY STEPHENSON, M.B., C.M. EDIN., F.R.C.S. EDIN., D.O. OXF.

Sydney Harry Stephenson, who died at his residence in Welbeck-street, London, on Dec. 15th, aged 61, was son of the late Dr. Appleby Stephenson, and was educated privately at Nottingham High School, afterwards entering Epsom College. He studied medicine at Middlesex and St. Mary's Hospitals, and having qualified L.S.A., he graduated at Edinburgh University in 1884. In 1889 he obtained the Fellowship of the Royal College of Surgeons of Edinburgh. Devoting himself to the study of ophthalmology, he held successively the posts of ophthalmic surgeon to Queen Charlotte's Hospital, to the Evelina Hospital, to the King Edward Memorial Hospital, Ealing, and at the time of his death was consulting ophthalmic surgeon to the Queen's Hospital for Children.

Stephenson rendered a great service to the community by his work on trachoma. He was in charge for two years of the "ophthalmia" school at Norwood, established after a serious outbreak in the London schools during the summer of 1886. Here all the children found to have granular lids were segregated, their teaching being in the hands of a resident governess. Other experiments on similar lines were made in the following years. In 1890, after an outbreak of trachoma at the Metropolitan Poor-law Schools at Hanwell, an isolation block designed for 400 children was erected, and Stephenson's services were engaged to look after their ocular condition. The proportion of trachomatous children in the Hanwell schools gradually diminished from 33 per cent. in 1889 down to 0·6 per cent. in 1896. In the latter year Stephenson was asked by the Local Government Board to undertake an inspection of the whole number of children attending the metropolitan Poor-law schools, when he found 973, or 5·72 per cent., suffering from trachoma; his recommendation was adopted to house these children in a couple of hospital schools on the "cottage" or "small block" plan.

When the Oxford Ophthalmological Annual Congress was formed by the late R. W. Doyne in 1909 out of the Oxford ophthalmological meeting, Stephenson was unanimously elected as secretary. In that capacity, with Doyne as Master, he laid the foundation of the Congress well and truly, and when, some five years later, he succeeded Doyne in the office of Master, a post he held to the day of his death, he established himself at once as a great successor to the brilliant founder. Under his mastership the Congress grew in membership and popularity, and it must have been a matter of deep satisfaction to him that the last Congress in July of this year, at which he presided, was a record one in attendance and keenness. His older colleagues will remember him as one of the most frequent contributors to the discussions at the Ophthalmological Society (of which he was secretary, later vice-president) for some 30 years. He was also a member of the Société Française d'Ophtalmologie, an hon. member of the Midland Ophthalmological Society, and an hon. Fellow of the American Academy of Ophthalmology and Oto-Laryngology. He had an extraordinary capacity for work as was evidenced in the publication of some 14 volumes of the *Ophthalmoscope*. This latter journal afterwards became incorporated in the *British Journal of Ophthalmology*, of which Dr. Stephenson was one of the associated editors. He was the author of "Ophthalmic Nursing," which has gone through three editions; "Epidemic Ophthalmia: Its Symptoms, Diagnosis, and Management," published in 1895; "Eyestrain in Everyday Practice," published in 1913; and, with Mr. W. A. Brailey, he wrote the article on Diseases of the Iris and Ciliary Body in the "System of Diseases of the Eye," published in Philadelphia in 1897. He also contributed to the Encyclopædia Medica, and made translations of Dr. Feuer's "Die Beziehungen zwischen Zahn- und Augen-Affectionen," and of Dr. Darier's "Leçons de Thérapeutique Oculaire."

Although an able clinician, Dr. Stephenson's chief interest was in journalism. He wrote well and with great care. He spoke well, weighing his words with a view to their effect, and whether he showed cases or wrote papers, they were always finished products. His knowledge of men and an unusual memory for faces, combined with a genial bearing and energy, were invaluable assets to every society in which he played a part. In a scientific meeting he was in his element and thoroughly enjoyed himself, making others do the same. He was a man ever ready to help and to do so in a way so unobtrusive that it was often not until long after that the source of the help was realised. Stephenson's health was never good. For long partially crippled, his last years were quite incapacitated, but with amazing pluck he stuck to his work when others would have given in to overwhelming disability.

Dr. Stephenson married Jane Finch, daughter of Mr. J. H. Peck, J.P. for Southport and Wigan.

ROBERT WALMSLEY FISHER, M.D., B.CH., D.P.H. (R.U.I.)

BY the recent death of Dr. R. W. Fisher, Director of the Vaccine Institute, Belgaum, in his forty-ninth year, the Public Health Department of Bombay has lost one of its most indefatigable and devoted workers. Dr. Fisher, son of Mr. Thomas Pentland Fisher, was born at Ballymena, co. Antrim, Ireland, in 1874. He began his medical studies at the Royal University of Ireland, and graduated M.B., B.Ch. in 1901. After holding appointments as resident medical officer of fever and small-pox hospitals in Belfast, followed by a short experience of general practice, he offered his services to the Secretary of State for plague work in India. He was allocated to the Punjab, and served in the Punjab Government for about four years. On his return to Ireland he took the D.P.H. (R.U.I.) in 1909. In 1911 the Secretary of State sanctioned the creation of an appointment of director of the Vaccine Institute, Belgaum, which was offered to Fisher in recognition of his services. During the war Fisher acted, in addition, as civil surgeon to Belgaum, and as medical officer in charge of the hostile women's camp, Belgaum. In 1921 his thesis on the History and Work of the Vaccine Institute, Belgaum, for the M.D. Belfast was awarded a gold medal, and was published in the *Indian Journal of Medical Research* (vol. viii., No. 2, 1920). As a tribute to his enthusiastic and painstaking labours for the Vaccine Institute he was awarded the Kaisar-i-Hind medal in June, 1923. In his various spheres of work Fisher was genuinely admired, not alone for his ability, but as a man of generous heart and disposition, ever ready to promote and foster good fellowship and to spend himself in the interests of others. He leaves a widow, a daughter, and two sons, the elder of whom has just entered on his studies in medicine at the Royal University of Ireland.

PRESENTATION TO PROF. ALEXIS THOMSON.—In the surgery class-room of the Edinburgh University on Dec. 12th an antique silver basin, with inscription, was presented to Prof. Alexis Thomson, who has been forced through illness to give up the chair of Surgery, by the members of his last class, and others of his students who cared to contribute, as a token of esteem and regard.

Medical News.

University of Oxford.—In a Congregation held on Dec. 15th the following degrees were conferred :—

D.M.—M. E. Shaw, New College.

B.M., B.Ch.—O. D. Ballinger, University ; D. T. Barnes, St. John's ; A. M. Cooke, Jesus ; R. S. Creed, Trinity and Magdalen ; Alice E. Harding, Oxford Home Students ; L. N. Jackson, Balliol ; J. A. Macfadyen, Brasenose ; G. F. L. Mitcheson, Christ Church ; T. L. Ormerod, Queen's ; T. S. Townsend, Jesus ; and H. F. Turney, Magdalen.

The following candidates passed the Final Examination for the degrees of B.M., B.Ch., in the subjects named :—

Materia Medica and Pharmacology.—C. P. Blacker, Balliol ; W. H. Bradley, Christ Church ; H. A. Byworth, Oriel ; J. N. C. Ford, Hertford ; A. T. Fripp, Christ Church ; A. H. Gale, Trinity ; C. L. Harding, Christ Church ; G. G. Hill, Hertford ; H. O. Hopkins and T. C. Hunt, Magdalen ; J. S. Jerome, Christ Church ; M. J. W. Minshull, Keble ; J. S. Rake, Brasenose ; C. E. Roberts, Jesus ; J. de la Mare Savage, Wadham ; J. G. S. Thomas, and O. R. Tisdall, Hertford ; A. L. Wilkinson, Trinity ; K. G. Norton, St. Hugh's ; and J. M. Vaughan, Somerville.

Pathology.—L. J. Barford, Queen's ; C. P. Blacker, Balliol ; R. B. Bourdillon, University ; W. H. Bradley, Christ Church ; C. S. Broadbent, Queen's ; R. V. Facey, Brasenose ; L. N. Jackson, Balliol ; T. L. Ormerod, Queen's ; R. A. Walsh, Magdalen ; O. B. Buckley, Somerville ; and E. J. Cockram, Society of Oxford Home Students.

Forensic Medicine and Public Health.—G. R. P. Aldred-Brown, Keble ; W. H. Bradley and R. E. D. Cargill, Christ Church ; A. D. Dyson, Corpus Christi ; C. L. Elgood, Balliol ; D. R. Gawler, University ; C. A. H. Green, Trinity ; L. N. Jackson, Balliol ; W. J. E. Lupton, New ; H. A. Robertson, Balliol ; V. P. Robinson, St. John's ; B. G. Scholefield and I. M. Sidley, Christ Church ; B. E. Thompson, Brasenose ; G. I. Wilson, Queen's ; and A. E. B. Harding, Society of Oxford Home Students.

Medicine, Surgery, Midwifery.—O. D. Ballinger, University ; D. T. Barnes, St. John's ; A. M. Cooke, Jesus ; R. S. Creed, Magdalen ; L. N. Jackson, Balliol ; J. A. Macfadyen, Brasenose ; G. F. L. Mitcheson, Christ Church ; H. A. Robertson, Balliol ; B. G. Scholefield, Christ Church ; E. B. Strauss, New ; T. S. Townsend, Jesus ; H. F. Turney, Magdalen ; A. E. B. Harding, Society of Oxford Home Students ; and J. Orr-Ewing, Lady Margaret Hall.

Royal College of Surgeons of England.—At a meeting of the Council of the College on Dec. 13th, Sir John Bland-Sutton, President, in the chair, the secretary reported the death on Nov. 8th, at the age of 73, of Mr. William Harrison Cripps, past Vice-President and member of the Council ; and also the death on Dec. 7th, at the age of 70, of Sir Frederick Treves, Bt., past member of the Council and of the Court of Examiners. A vote of condolence was passed in each instance. Diplomas of Fellow were conferred upon the following 25 candidates who have passed the requisite examinations and complied with the by-laws :—

Douglas J. Batterham, Cambridge and St. Bart.'s ; John M. Bickerton, Cambridge and King's Coll. ; Harold C. Brayshaw, Edinburgh and London ; Leonard G. Brown, Oxford and London ; Calvert M. Carruthers, Kingston and London ; William D. Doherty, Guy's ; William C. Faull, St. Mary's ; Lionel R. Fifield, London ; William D. Hart, Otago and London ; Reginald W. P. Hosford, St. Bart.'s ; Michael V. Hurley, Cork and London ; S. Kadinsky, Westminster and Guy's ; Hugh B. Kent, Guy's ; John R. Lee, Melbourne and Middlesex ; Hugh J. McCurrich, St. Bart.'s ; S. M. Majumdar, Calcutta and St. Bart.'s ; William E. M. Mitchell, St. Bart.'s ; Thomas S. North, St. Mary's ; Norman A. M. Petersen, London ; Granville D. Robertson, St. Mary's ; William G. Rose, St. Mary's and St. Bart.'s ; Thomas C. Summers, London ; Clement P. Thomas, Westminster ; Dallas B. Walker, Otago and Edinburgh ; and Owen H. Williams, Edinburgh and Liverpool.

Licences in Dental Surgery were conferred upon the following 119 candidates who have passed the requisite examinations and have complied with the by-laws :—

F. G. Alford, Royal Dental ; H. W. Allso, Birmingham ; Katherine M. Ambler, Royal Dental ; S. Bain, Sheffield ; G. A. Ballantyne, London ; R. C. Ballard, Guy's ; E. T. Barlow, Liverpool ; O. J. Barrable, Royal Dental ; T. S. L. Barritt, Guy's ; M. Batey and M. L. Bendi, Royal Dental ; T. B. Berry, Guy's ; A. D. Blackwell and W. M. Bowler, Royal Dental ; W. S. Brittan, Guy's ; C. F. S. Brooks, Manchester ; J. K. R. Bryce, Univ. Coll. ; L. S. Carter, Guy's ; G. R. Catchpole, London ; H. F. Caudwell, Royal Dental ; E. F. Cook, Birmingham ; W. O. Cooksey, D. H. Couch, and I. G. Coutts, Guy's ; E. R. Cozens, London ; Florence E. Crampton, Royal Dental ; D. J. Dalton, Durham ; Brenda M. Daniels, Royal Dental ; W. W. F. Dawe, Univ. Coll. ; H. T. Deubler, Royal Dental ; R. C. De Waal, London ; J. A. Dodds, Manchester ; F. S. Duck, London ; H. B. Dumughn, Manchester ; A. H. Dyke, Guy's ; C. D. W. Eddowes, London ; R. W. Ellis and Doris M. Elvy, Royal Dental ; C. H. A. Fido and E. H. Fouraker, Guy's ; E. W. F. Fowler, Royal Dental ; L. A. Freeman, London ; S. G. French, Guy's ; N. H. Galloway, Birmingham ; H. C. Goadby, Edith A. Gower, N. J. Graham, Helen M. Greatorex, H. R. Griffin, W. D. Guyler, and H. W. Haggett, Royal Dental ; L. F. Handford, Guy's ; F. E. Harrison, Liverpool ; O. J. Henry, Leeds ; C. N. Hilton, London ; C. E. H. Ockley, Royal Dental ; W. V. A. Hodges, Guy's ; D. S. Hotz, Royal Dental ; F. B. Howarth, Manchester ; E. T. Hughes, London ; F. Innes, Durham ; P. Johnson, London ; L. H. Jones, Guy's ; F. Kogan, Royal Dental ; G. A. Lawson-Brown, Guy's ; E. H. Lewis, Sheffield ; C. D. Lingwood, Guy's ; E. A. Lister, Univ. Coll. ; J. E. Lloyd, Guy's ; G. W. Lund, P. Lunt, and A. P. Marais, Royal Dental ; R. S. Matthews, M. W. Meskin, and H. Metheringham, Guy's ; L. E. Montgomery, Royal Dental ; A. L. Morgan, Bristol ; A. E. Nelson, Guy's ; W. R. Norris, London ; L. Nurick and W. Orsmond, Guy's ; S. H. Partridge and Muriel C. Patching, Royal Dental ; E. Z. C. Pearson, Guy's ; H. D. Peckover, Royal Dental ; F. O. E. Peres, Univ. Coll. ; C. R. Philip, Royal Dental ; E. V. Potts, Guy's ; H. Prior and R. H. Reece, Royal Dental ; E. R. Rich, Univ. Coll. ; P. W. Rogers, London ; R. A. Roth and C. H. Rubra, Royal Dental ; N. H. Saint, Guy's ; O. Samson, Royal Dental ; E. H. L. Sander and S. S. Sanderson, Guy's ; R. Schlimmer, Guy's ; J. W. Schofield, Royal Dental ; G. P. Stanfield, Birmingham ; W. H. P. Stone, Univ. Coll. ; G. S. Sturgess, G. H. Tapper, G. E. Taylor, and E. D. Thomas, Royal Dental ; L. J. Threlfall, London ; T. Vallange, G. J. van Schalkwyk, and C. A. Wakeford, Guy's ; A. E. Ward and A. W. T. Ward, Univ. Coll. ; E. M. Ward, Birmingham ; V. C. Warr, Guy's ; E. C. E. Williams, Birmingham ; H. Williamson, Royal Dental ; L. C. Willis, Guy's ; F. G. B. Wilson, Durham ; and J. M. Wolfe, Royal Dental.

Diplomas of M.R.C.S. were conferred upon the following :—

Miriam P. de Villiers, Royal Free ; and H. C. Suri, Punjab and London.

A report was read from the Board of Examiners in Dental Surgery announcing, among other things, that the Board had considered an application from King's College Hospital Medical School for the recognition of a School of Dental Surgery in connexion with that medical school which had recently been established ; the Board recommended the Council to add King's College Hospital Dental Department to the list of dental schools recognised for the course of study for the licence in dental surgery. This report was adopted.—Mr. V. Warren Low was re-elected a Member of the Court of Examiners.—Mr. W. G. Spencer was re-elected a Member of the Central Council for district nursing in London for three years from Jan. 1st, 1924.—Sir Berkeley Moynihan was reappointed a Member of the Court of the University of Birmingham for three years from Jan. 1st, 1924.

University of London : *University College.*—Six scholarships and exhibitions are available for award to students of the Faculty of Medical Sciences entering the College in October, 1924. The value of these scholarships and exhibitions is not less than £40 a year each, tenable in some cases for three years, and, in the case of the Bucknill Scholarship, for the whole period of medical education. The value of any of these scholarships or exhibitions may be increased by the grant of a supplementary bursary if the circumstances of the scholar or exhibitioner make such a grant necessary.

University of Liverpool.—At examinations held recently the following candidates were successful :—

Degree of M.D.

J. Flanagan and Annie A. Muir.

Degrees of M.B. and Ch.B. (Honours).

Class II.—B. Ordman (distinction in Surgery).

Final Examination for Degrees of M.B. and Ch.B.

Part III.—R. L. Blair, I. Casdan, M. Cohen, N. B. Cooke, J. C. Drummond, Kathleen Edgecombe, C. K. D. Edwards, D. Flenley, E. J. Foley, S. C. Goldstone, A. B. Griffiths, R. C. Gubbins, A. J. Hawe, C. W. Healey, F. H. Jones, W. F. Jones, A. Kefalas, T. S. King, Ruth Lunt, G. H. Mann, J. I. Noble, D. U. Owen, Eleanor M. P. Pearson, R. A. Roberts, G. Sanders, J. R. A. Tallack, Elizabeth M. Theron, J. G. Thomas, R. W. Thomas, H. Walker, and A. E. Wall.

Part I.—*A. T. Ashcroft, *C. A. Birch, J. M. Brodrick, N. Cresswell, H. L. Cullen, P. V. Dillon, L. Earlam, Sybil O. Edwards, W. Emdin, C. J. S. Garton, I. Gordon, A. J. Goss, Frances M. Greenhalgh, Catherine E. I. Greenshields, Gwyneth Griffith, C. A. Harris, Beryl M. Hawthorn, J. C. Heal, R. E. Horsfall, F. Hughes, Elvy I. Johnstone, S. M. Katz, B. D. Knoblauch, B. Krikler, Sarah Leigh, L. J. A. Loewenthal, T. R. E. Longton, *G. McNichol, E. Martinez, K. N. Mawson, J. Morrissey, Winifred A. Nicholson, G. W. Paton, H. Peaston, J. W. Reid, Kathleen M. Robertson-Dunn, *Miriam Roskin, J. C. Ross, F. B. Shevlin, Ruth Simpson, Margaret E. Thomas, R. S. Turner, C. E. Unsworth, J. Unsworth, Rosalind Vacher, and F. W. Yates.

* Distinction in Pathology.

Part II.—C. P. Allen, A. Ashworth, C. Baxter, T. Bellis, D. Cohen, H. A. Cole, E. Cook, J. D. Craig, O. Dawood, H. Duff, J. H. Gilchrist, L. F. Henry, T. S. L. Jones, Rebecca Katz, A. L. Kerr, B. D. Knoblauch, B. Krikler, E. Martinez, J. R. Mitchell, and R. S. Turner.

Diploma in Tropical Medicine.

B. Abelman, Winifred M. Edghill, N. D. Fraser, R. Lee, E. R. Peirce, C. B. B. Reid, A. E. Richmond, and J. B. Steven.

Small-pox in England and Wales.—A further increase in small-pox has occurred. Sixty cases were notified in England and Wales during the week ended Dec. 8th in the following sanitary areas: Cheshire 1 (Chester); Derbyshire 24 (Alfreton 1, Bolsover 5, Heanor 4, Blackwell R.D. 14); Gloucestershire 16 (East Dean R.D.); Northumberland 1 (Morpeth R.D.); Notts 14 (Hucknall 7, Kirkby-in-Ashfield 3, Basford R.D. 4); Yorks, W.R. 4 (Adwick-le-Street 3, Bentley-with-Arksey 1).

Remuneration of Insurance Practitioners.—The Court of Inquiry appointed by the Minister of Health and the Secretary for Scotland to consider the question of the remuneration of Insurance practitioners held a private meeting on Dec. 13th at the Ministry of Health, and considered questions of procedure. Meetings for the purpose of hearing evidence will take place on Jan. 4th, 1924, at 10.30 A.M., and on Jan. 7th and 8th, at the Ministry of Health, Whitehall, S.W. 1. These meetings will be open to the public and the press.

Manchester Hospitals.—At the annual meeting of the Hospital Fund held in Manchester on Dec. 12th it was pointed out that the difference between the annual income and annual expenditure of the hospitals was £51,000, a deficit largely made up of charges upon the hospitals of patients coming from outside Manchester and the Borough of Salford. These outside patients cost £95,000, and the contributions in respect of them amounted to £44,000. Some very prosperous resorts favoured by Lancashire business men gave but meagre financial support. Manchester needed more organisation and coördinated effort if more funds were to be obtained.

Royal College of Physicians of Edinburgh.—At the annual meeting of the College held on Dec. 6th Dr. George Lovell Gulland was elected President of the College for the ensuing year. Sir Robert Philip, Drs. J. C. Dunlop, R. A. Fleming, Robert Thin, Lamond Lackie, and Edwin Matthew were elected members of the Council, and Drs. Dunlop and Claude B. Ker as representatives of the College on the board of management of the Royal Infirmary. The other office-bearers of the College for the ensuing year are as follows: Vice-President, Dr. Dunlop; Treasurer, Sir Norman Walker; Hon. Librarian, Dr. Thin; Curator of Research Laboratory, Sir Robert Philip; Secretary, Dr. J. S. Fowler.

Bethlem Royal Hospital.—A course of lectures and practical instruction for the Diploma in Psychological Medicine granted by the various universities is given at Bethlem Royal Hospital twice yearly during the spring and autumn. The next course, which will begin on Jan. 14th, 1924, will conclude in April and is divided into two parts—A and B. Part A deals with the anatomy, histology, and physiology of the nervous system and psychology, and Part B consists of lectures and demonstrations of neurology, psychological medicine, and mental deficiency. Clinical instruction in psychological medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 o'clock. Further particulars may be obtained from the Physician-Superintendent at the hospital, S.E. 1.

Royal Medical Benevolent Fund.—At the last meeting of the Committee 30 cases were considered, and £350 was voted to 22 applicants. The following is a summary of some of the cases relieved :—

Daughter, aged 77, of M.R.C.S. who practised at Market Drayton and died in 1878. She has been given a home and an allowance of £26 per annum for some years by a cousin who died in May last, and now she has to find other accommodation. Friends have helped her to the extent of £25 since December and she asks the Fund to give her some assistance. Voted £26 in 12 instalments.

Daughter, aged 39, of M.R.C.S. Eng. who practised near Rugby and died in 1902. Applicant has supported herself as a governess and owing to periods of unemployment has had a hard struggle to make ends meet. Her expenses during six months unemployment were about £52 and her total income amounted to about £70. She asks the Fund to give temporary assistance. Voted £10.

Widow, aged 66, of L.R.C.P.I. who practised at Worksop and died in a nursing home in Ireland in 1917. Applicant's late husband was unable to make any provision for his wife or family as he had to retire from practice owing to a mental breakdown. The son is unable to give any help and one daughter is married. The remaining daughter lives with her mother and shares expenses. Applicant had a temporary Government appointment which has now ceased, owing to ill-health. Voted £3 in two instalments as from Dec. 1st, and case to be reconsidered at the next meeting.

M.R.C.S. Eng., aged 60, who practised in Wales and through paralysis had to give up practice in 1892. Up to 1921 applicant's board, lodging, and attendance were paid out of his annuity, supplemented by friends' gifts and help from a brother. This brother retired from the Navy and is unable to give the same help. He applied to the Fund and the Committee voted £26 in 12 instalments. In 1922 this was repeated and at this meeting again renewed.

Daughter, aged 70, of M.R.C.S. Eng. who practised in the Isle of Wight and died in 1870. Owing to chronic ill-health applicant is quite unable to support herself. She lives with an old nurse and pays 3*s.* 6*d.* per week rent. Her only income is £20 from the Home for Incurables and the Old Age Pension. Voted £10 in two instalments.

Subscriptions may be sent to the hon. treasurer, Sir Charters Symonds, K.B.E., C.B., M.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

The seventh course of lectures for the Diploma in Psychological Medicine will begin at the Maudsley Hospital on Jan. 21st, 1924, under the direction of Sir Frederick Mott.

National Hospital for the Paralysed and Epileptic.—A post-graduate course on Diseases of the Nervous System will be held from Feb. 4th to March 28th, 1924. The general course will consist of clinical lectures and demonstrations, teaching in the out-patient department, and pathological lectures and demonstrations. A course of lectures on the Anatomy and Physiology of the Nervous System will be arranged if there are sufficient applicants. A course of clinical demonstrations, chiefly on Methods of Examination of the Nervous System, will be given. A course of eight lectures and six demonstrations on Neurological Ophthalmology to a limited number of students will also be held. A certain number of students can be enrolled as ward clerks or as clinical assistants in the out-patient department. Further particulars may be obtained from the Secretary, Medical School, National Hospital for the Paralysed and Epileptic, Queen-square, London, W.C. 1.

The late Lord Willoughby de Broke.—Lord Willoughby de Broke, nineteenth Baron, whose death occurred on Dec. 16th, besides taking a front place in politics, sport, and the arts, was always greatly interested in medicine, and especially in preventive medicine, in its relation to the reduction of venereal disease. On several occasions he raised the subject of the prevention of venereal disease in the House of Lords, and in 1919 took a leading part in launching the Society for the Prevention of Venereal Disease, accepting the Presidency of this Society, and the chairmanship of its Executive Committee. In combination with Lord Dawson and Lord Trevethin he helped to end the venereal controversy by bringing his own Society and the National Council for Combating Venereal Disease into line on the terms of the Trevethin Report, and one of his last acts, prior to his illness, was to visit Lord Trevethin with the object of discussing their proposed joint deputation to the Minister of Health. When he had formed a definite opinion as to what was the right course to pursue, he was not to be deflected from his goal, and courageously and determinedly followed his line. He earned the respect and affection of all who worked with him, and even those whose opinions differed most widely from his bore him no grudge.

The National Health Insurance Act in the Irish Free State.—The Irish National Health Insurance Commission made an important communication to the representatives of the Irish Medical Committee last week. Since the beginning of 1916 certification for benefits under the Act has been performed by the medical profession generally, the remuneration being provided by a special Government grant. The Minister of Finance in the Free State Government has notified the Commission of his inability to continue the grant. In the circumstances the Commission has looked round to find what funds it can make available for carrying on a necessary service. By obtaining a small contribution from the approved societies, and by calling on certain floating funds which can be put at he disposal of the Commission, sufficient moneys can be found to provide remuneration at about 3*d.* per head per insured person less than hitherto. At present, owing to an increased remuneration due to a war bonus, only part of which was taken off, the profession is paid 20 per cent. more than when the scheme was put into operation in 1916. If the profession now agrees to the reduction proposed by the Commission, the remuneration will return to a fraction above its original level. The statement of the Commission on this point was accompanied by an assurance that the offer, if agreed on, would be for one year only, and that early in 1924 the Government was to undertake an inquiry into the entire working of the National Health Insurance Acts in Ireland. Our Irish correspondent adds: It is to be hoped that such an inquiry will look into the whole question of the public medical services, without which the consideration of the question of medical benefits would be sterile. The Irish Medical Committee has not yet met to consider the communication from the National Health Insurance Commission.

THE MIDDLESEX HOSPITAL CONVERSAZIONE.

STAFF, students, and nurses of the Middlesex Hospital and Medical School were "At Home" on the evening of Dec. 18th, and so well organised was their reception of a very large number of guests, including the Prince of Wales, that all these seemed to feel at home also. The itinerary through the hospital and medical school was clearly mapped by sign-posts, and it was not advisable to move against the traffic. Section I. included the operating theatres and instrument rooms, where demonstrations of midwifery forceps appeared to have a special fascination for the general company, and the electrical and radiological departments. The anatomy and physiology departments made up Section II., while perhaps even more attractive, though apparently less frequented exhibits were available in Section III., which was reached by devious paths after passing through the other sections. In the anatomy department a series of stereoscopic photographs of dissected hearts suggested a useful means for students of revising and confirming impressions of their own dissections. Some very beautiful slides were on view in the same room. In the pathological department outstanding exhibits were those of the methods of growing anaerobic bacteria—the pathology of gas gangrene and tetanus had to be explained to a succession of enthralled listeners—and of the methods by which insulin is actually being made for hospital use. Even those who remain dubious as to the physiological value of alcohol must have been impressed by its remarkable efficiency in the laboratory, first in destroying the trypsin-secreting tissue of the ox pancreas, which is the raw material used, and at a later stage in precipitating the insulin from the concentrated watery solution to which this material has been reduced. Another exhibit was the demonstration of the treatment of boils by vaccines, in which the pus, the syringe, and the preparation of vaccines were shown, the final stage of the exhibit—and it is to be hoped of the boils—being the injection into an arm. Demonstrations of ultra-violet rays, of some newer laboratory methods of investigating disease, and of changes in the tissues in disease also received much attention. The whole impression was that of a hospital and school alive to its responsibilities alike for the care of the sick, for research, for the training of students and nurses, and, not least, for educating the public to appreciate the problems of medicine and the efforts being made for their solution.

Appointments.

BIGLAND, A. D., M.D., Ch.B. Liverp., M.R.C.P. Lond., has been appointed Honorary Assistant Physician, Liverpool Royal Infirmary.

BULMAN. M. W. B., M.S. Lond., F.R.C.S. Eng., Honorary Assistant Surgeon to the Norfolk and Norwich Hospital.

DAVIES, E. C., M.Sc. Manch., Assistant Lecturer in Chemistry at the Natal Technical College, Durban, South Africa.

HADFIELD, G., M.D. Lond., Consulting Pathologist to the Southmead Infirmary, Bristol.

HEADRIDGE, D., L.D.S., Lecturer in Dental Anatomy and Physiology, University of Manchester.

ORSMOND, E., M.R.C.S., L.R.C.P. Lond., House Physician, St. Bartholomew's Hospital.

TIBBLES, J. R., M.B., Ch.B., M.R.C.S., L.R.C.P., Resident Medical Officer, Willesden Health Department.

Salford Royal Hospital: PETERSON, N., M.B., B.S. Lond., F.R.C.S. Edin., F.R.C.S. Eng., Resident Medical Officer; GHOSH, J., F.R.C.S I., D.P.H., Anæsthetist (re-elected).

Vacancies.

For further information refer to the advertisement columns.

Bournemouth, Royal Victoria and West Hants Hospital.—Res. H.S. £150.

Chesterfield and North Derbyshire Hospital.—Res. Surg. O. and Sen. H.S. £300 and £200 respectively.

Dreadnought Hospital, Greenwich.—H.P. £150.

Exminster, Devon Mental Hospital.—Third Asst. M.O. £300.

Harefield, Middlesex County Tuberculosis Sanatorium.—Third Asst. Res. M.O. £400.

Hastings, Royal East Sussex Hospital.—Hon. S. and Hon. P.

Hospital for Sick Children, Great Ormond-street, W.C.—Biochemist. £600. Res. Med. Supt. £300.

Hull, Victoria Hospital for Sick Children, Park-street.—R.M.O. £100.

Liverpool, Royal Southern Hospital.—Hon. M.O. Electro-therapeutic, &c., Dept., and Hon. M.O. Electro-cardiographic Dept.

Loughborough and District General Hospital and Dispensary.—Res. H.S. £175.

Manchester, Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—Sen. and Jun. H.S.'s. £150 and £100 respectively.

Manchester Royal Infirmary,—Sen. and Jun. Pathological Registrars. £100 and £50 respectively.

Middleton-in-Wharfedale Sanatorium, near Ilkley.—Asst. Res. M.O. £350.

Orkney, Parish of Eday.—M.O.

Reading, Royal Berkshire Hospital.—H.P. Also Third H.S. Each £150.

Royal Army Medical Corps.—Commissions.

St. Bartholomew's Hospital.—Radiologist. £500 to £1000.

Sunderland Royal Infirmary.—H.S. £140.

Union of South Africa, University of the Witwatersrand.—Senior Lecturer in Anatomy. £450.

West End Hospital for Nervous Diseases, 73, Welbeck-street, W.—Cas. P. £200.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Cockermouth, Cumberland.

The Secretary of State for the Home Department gives notice that he proposes to appoint a second Medical Referee under the Workmen's Compensation Act. 1906, for the Barrow-in-Furness and Ulverston, Kendal, Kirkby Lonsdale. and Windermere County Courts in Circuit No. 3. Application for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than Jan. 5th, 1924.

Births, Marriages, and Deaths.

BIRTHS.

BATTERHAM.—On Dec. 12th, at Stone Field, Kidbrook-grove, Blackheath, the wife of Captain D. J. Batterham, R.A.M.C., of a daughter.

HODGSON-JONES.—On Dec. 8th, at St. Agnes, Caterham-on-the-Hill, the wife of Dr. R. W. Hodgson-Jones, of a daughter.

MARRIAGES.

MOLESWORTH—HOARE.—On Dec. 15th, at St. Marylebone Parish Church, Hickman Walter Lancelot Molesworth, F.R.C.S., to Caryl Margaret, daughter of Mr. and Mrs. Stanley Hoare, of Cornwall-terrace, Regent's Park, N.W.

DEATHS.

CLAPP.—On Dec. 9th, at St. Leonard-road, Exeter, George Tucker Clapp, M.B. Camb., M.R.C.S., aged 66.

GOGGIN.—On Dec. 16th, at Folkestone, George Taylor Goggin, late Colonel, R.A.M.C., aged 72.

HOLLINGS.—On Dec. 10th, after three days illness, Edwin Thomas Hollings, M.R.C.S., L.R.C.P., of Jamaica-road, London, S.E.

MARSHALL.—At 1, Douglas-crescent, Edinburgh, on Dec. 16th, Lieut.-Colonel D. G. Marshall, I.M.S. (retired).

STEPHENSON.—On Dec. 15th, at his residence, Welbeck-street, Sydney Harry Stephenson, M.B., F.R.C.S Edin., D.O. Oxf.

SWAN.—On Dec. 13th, at a nursing home, following an operation, Charles Robert John Atkin Swan, O.B.E., M.B., B.Ch. Oxf., of Chester-place, Hyde Park, aged 60.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

DONATIONS AND BEQUESTS.—By the will of the late Lieut.-Colonel Alfred Conway Bishop, the testator left £500 each to Charing Cross Hospital, the London Hospital, St. George's Hospital, the West London Hospital, and the Given-Wilson Institute, Plaistow, E.; £200 each to the East London Hospital for Children, Shadwell, St. Mary's Hospital, Plaistow, the Hospital for Sick Children, Great Ormond-street, and the London Lock Hospital.—Mrs. Margaret Dacre, of Carlisle, left £1000 each to the Cumberland Infirmary, and the Free Home for the Dying, London, for a bed in memory of her husband.

Notes, Comments, and Abstracts.

ON THE HUMANITY OF METHODS OF SLAUGHTER.

BY LEONARD HILL, M.B., F.R.S.,
DIRECTOR, DEPARTMENT OF APPLIED PHYSIOLOGY, NATIONAL INSTITUTE OF MEDICAL RESEARCH

WHILE blood is a medium in which microbes readily grow, muscle is far more resistant to their invasion; this is because each muscle fibre is not only enclosed in a homogeneous membrane, but turns acid after death. The more blood therefore left in flesh, the greater will be the tendency to putrefaction, and the less the keeping quality. Every good housewife knows that flesh left lying on a dish turns faint quickly where oozings of blood touch it; she also knows that to keep suet sweet, the lumps of fat must be broken up and freed from blood-vessels and connective tissue, and then kept dry in flour to which it gives up its moisture.

Traditional Methods of Slaughter.

Now the butchers claim that animals killed by being shot in the brain cannot be so well drained of blood and lymph as those killed by the old traditional methods. In consequence, the flesh is moister, not so firm, weeps drops of blood and serum when cut, while the fat is softer and is not so white and shows spots and streaks of blood in places. The bacon-curers also say that the carcasses of pigs killed by shooting show extravasations or "blood-splashings" which are so disfiguring that competition with the bacon and ham of animals slaughtered by the old method—that is, by cutting the big arteries in the neck and bleeding—is out of the question, and therefore their trade will be ruined if the shooting method is made compulsory. These contentions are reasonable, and have, as I shall show later, a solid basis of physiological science behind them. They are supported by the photographs of bacon splashed with blood, which were given me by a bacon-curer, and are confirmed by the results of a recent test of the various methods of slaughter conducted by the Birmingham authorities at their public abattoir. I was one of those invited to witness there the killing of oxen, sheep, and pigs by means of various safety pistols and by the old method—viz., the pole-axe for oxen and throat-cutting for oxen (Jewish method), and the latter for sheep and pigs. It is generally assumed by laymen that the shooting is much more humane than the older methods. They suppose that the cutting of the throat is a most painful operation, and that struggling movements are necessarily a sign of pain. Educated in the false ideas and statements of writers of romance they are easily led astray by agitators having no knowledge of physiological science, nor surgical experience. Now the surgeon knows that sudden big injuries are not felt at the time of their infliction. He knows, moreover, that structures beneath the skin, apart from sensory nerves, are insensitive to the knife. It is well known that men injured in battle—severely and perhaps fatally—often fight on unaware that they are wounded until they see the blood or become exhausted. At most the wounded feel a dull sensation of a blow and numbness in the injured part. Pain comes later when a wound becomes septic and inflamed. The merciful insensitiveness of man to severe injury was impressed upon me, when I was a young house surgeon, by two cases—one of a man with his pelvis crushed between the buffers of a train. Conscious, although collapsed, he was able to tell me that he had felt no pain; shortly afterwards he died of shock. A similar case was that of a man impaled by the shaft of an iron railing through falling out of a window.

Is Throat-cutting Painful?

In defending the Jewish method of slaughter from unjust attack, the distinguished surgeon, Mr. T. H. Openshaw, stated that several cases of throat-cutting, which surviving from their injury had come under his care at the London Hospital, were questioned by him. Not one of these had felt the cut when it was made. When a very sharp knife is used to cut the healthy (not inflamed) skin, very little pain is felt—even by a man who is expecting the cut—particularly so in parts, such as the back, which are not so trained to delicate sensibility as the finger-tips. Horses standing loose in a stall are bled from the jugular vein for the obtaining of antidiphtheritic serum; they continue during the operation to eat placidly at the manger. Sensitive as the horse is to the sting of a fly, or whip, or prick of a spur, it takes no notice of the cut of a sharp knife. The skin has been evolved sensitive only to those things which concern it in the natural struggle for existence, and deep structures, apart from sensory nerves, protected as they are by the skin, are wholly insensitive to touch. The touch of whip or spur is like the sting of a fly, and is therefore felt by the horse, which must protect himself against a natural enemy; on the other hand, the cut of a sharp knife is not a natural stimulus and is unfelt.

Of these facts laymen are, as a rule, wholly ignorant. As to the duration of consciousness after the cutting of the throat, I can cite an experiment made by myself some years ago when, together with Mr. Openshaw, I defended the Jewish method of slaughter. I anæsthetised a calf and inserted a tube in the peripheral end of the cartoid artery—that is, in the end connected with the arteries supplying the brain. It must be borne in mind that the vertebral arteries do not also supply the brain of cattle but end in the muscles of the head. The tube placed in the artery was filled with a strong saline solution to prevent clotting of the blood, and connected with a mercurial manometer arranged so as to record (on a revolving drum) the blood pressure. The animal's neck was then cut with a sharp knife so as to divide the great blood-vessels at one stroke. The manometer recorded an instant fall of blood pressure which reached zero in a second or two, showing that the circulation in the great brain had ceased. Now we know by human experience that such sudden cessation of the circulation by depriving the brain of oxygen instantly abolishes consciousness, whether produced by pressure on the brain or by heart failure, or by occlusion of the great blood-vessels of the neck. An old medical writer tells of a beggar in Paris who had a large hole in his skull covered with skin. He sat in the street and for a coin allowed a person to press upon his brain, when he fell asleep. The moment the pressure was withdrawn he became conscious again. The very word carotid betokens sleep. Mountebanks used to compress these arteries in a goat and make the animal fall down unconscious or spring up again at their will. The garrotter by compressing these arteries by a grip from behind rendered his victim unconscious while he robbed him of his watch and money. A schoolboy playing at hanging has lost consciousness through the sudden compression of these arteries and has died in consequence. This unhappy accident has been repeated through a general ignorance of the danger.

Adventitious Factors.

Two facts are, then, indisputably established: (1) that a big injury, such as throat-cutting, is not felt at the moment of infliction; (2) that the cutting of the big arteries in the throat instantly arrests the circulation in the great brain and abolishes consciousness. The actual operation of cutting the throat is, then, as humane as shooting with the safety pistol, or stunning with the pole-axe. Each of the last two methods requires the correct application to the skull of the weapon, and either may fail in a restive animal which happens to swerve at the critical moment. The cutting of the throat requires the casting of oxen and sheep and the holding of pigs or hoisting in the head-down position, but it cannot fail. Any charge of inhumanity can therefore be made justly not against the cutting of the throat, but only against the operation of casting, or hoisting. Now sheep are carried in and cast on their backs on a table whether for shooting or throat-cutting, so any such charge fails in regard to sheep. Oxen, by the Jewish method, are cast by a tackle fastened to their feet and to a hoist. Pigs have a tackle fastened to one hind leg and to a hoist. If both legs were fastened the animals would be able to jerk themselves up and down. At Birmingham an electric motor was used to both hoist and transfer each pig from the pen to the slaughterer. Nine pigs were thus slaughtered in a space of a little over five minutes. At a big bacon-curing factory pigs are slaughtered far more quickly than this—e.g., at the rate even of ten a minute. On the other hand, a minute or two were spent at the Birmingham tests by the operator manœuvring round each pig, free in a pen, in order to get the pistol in the proper position for shooting, and there was some risk to the operator and much skill required of him. He was an intelligent official, highly trained in the use of the pistol. The pigs may struggle violently after shooting, convulsed by the damage done to the brain. In one case the convulsions were so violent that the throat could not be cut for about three minutes after the shot had been fired. The time spent in shooting pigs is, then, much greater than that spent in cutting the throats of an equal number. So, too, in the case of sheep, shooting requires two operations in place of one, a serious matter when some hundreds of sheep are killed in one day; it also requires two men when one suffices to hold and cut the throat. Shooting means, then, dearer meat.

Animals, whatever be the method of slaughter, have to be driven to market and pushed, pulled, poked, and tail-twisted by drovers in order to make them go first into the pens outside and then into the slaughter-house itself. By no means can they escape some measure of rough handling. Casting of oxen or hoisting of pigs entails, in my judgment, handling which is no more inhumane than the rest. Conducted skilfully and with electrically-driven hoists these operations may occupy no more or even less time than that spent in forcing and roping an animal into position for shooting. In casting an ox by the Jewish method a mattress is used. Mr. Openshaw found no evidence of bruising post mortem ; it is obviously not to the advantage of the butcher to bruise the meat and cause extravasation of blood in the carcass. The butcher asserts that the more gently beasts are handled and the less driven the more tender the flesh. It is obvious that it is a disadvantage to exhaust the muscles and produce excess of lactic acid in them. A hunted animal at once goes into rigor mortis after death, and its flesh is tough.

The Consciousness of Animals.

It must be borne in mind that animals have no more consciousness of death than uneducated babies have. Man's recognition of the hideousness and horror of the slaughterhouse is the result of education. It is absurd to think—as sentimental people do think—that animals are conscious of the presence of a dead carcass, or spilt blood. Careful observation has convinced me—as it will any level-headed man—that animals in an abattoir are nervous of moving men, of drovers with their pushing, pulling, and tail-twisting, but so soon as they are left alone they become placid and indifferent to the sights about them. Pigs are naturally disturbed by the squeals of other pigs when caught and pulled from their pen, but no more so than when they are caught for the operation of nose-ringing. Whatever suffering there may be is separable from the actual operation of slaughter, and occurs in the process of driving the beast to and putting it into position for slaughter. Whether an animal is pushed, pulled, and tail-twisted into the right position for the pistol, or cast or hoist into the posture necessary for throat-cutting, appears to me, then, a matter of very small moment. As the result of human experience we must conclude that a cast or hoist animal will be so hypnotised by the unusual position into which it is suddenly put, that it will be able to take no further notice of anything going on around it. The layman must recognise that while an animal with its throat cut continues to breathe and move convulsively for some minutes, these convulsive movements are not signs of consciousness. The shot beast may be convulsed for no less a time. Such convulsions are due to acute anæmia of the power parts of the nervous system. Observation has shown me that the movements of the eyes of an ox become convulsed within a very few seconds of throat-cutting, a sure sign of the acute anæmia and dying state of the centres in the mid-brain. The great brain, where sits consciousness enthroned, ceases to function at once, the mid-brain next, the spinal bulb next, and last, the centres of the spinal cord.

It has been a custom of certain African savages, after decapitation of an enemy, at once to close the blood-vessels of the neck with a cautery, and then amuse themselves by exciting reflex movements in the corpse. No doubt the savage thinks his enemy feels his insults. It is well known that even movements of locomotion can take place in a lower animal the great brain of which has been destroyed. Thus, a fowl, after decapitation, runs round before it falls over. When from an anæsthetised cat the great brain is removed without loss of blood the body continues to carry on its functions, including respiration, and these functions may be studied by the physiologist for many hours. Nay, if the body of the animal is kept in a warm bath even for several days. The layman must discard his crude idea that movement betokens consciousness before he can form any just view of the humanity or inhumanity of a method of slaughter.

The Flesh of Shot Animals.

I now return to the contention of the butchers that the flesh of shot animals is moister and contains more blood. This was clearly shown by the Birmingham tests. Half carcasses of selected and representative animals killed by each method were reserved in a locked-up store and examined a week later. On cutting up the carcasses and comparing the flesh of the shot oxen with that of the ox killed by the Jewish method, it was clear that the flesh of the latter was firmer, drier, and free from blood. The flesh of the shot carcasses not only was moister and softer, but showed blood in the vessels. The flesh of the pole-axed ox appeared to me somewhat drier and freer from blood than that of the shot animals, but there was no striking difference. When the throat is cut by the Jewish method the centres in the lower parts of the nervous system—viz., the spinal bulb and cord—continue to act for a time. Deep, gasping respirations occur, and convulsive movements which press the blood out of the muscles and organs of the belly. The vaso-motor centre in the spinal bulb is excited by the acute anæmia and causes constriction of the arteries all over the body, the heart is accelerated in action, and the bowels undergo peristaltic movements which wring out the blood. The whole of these actions result in almost complete drainage of blood and tissue-lymph out of the body. When an animal is shot the slaughterers cut the throat—this after some period of delay—and then, respiration having stopped, try to imitate its effect by rocking the body with their feet. The bullet by explosive action may set up increased pressure in the skull, and so stimulate the inhibitory centre of the heart which lies in the spinal bulb, and thus temporarily stop the action of the heart. This is a well-known result of increasing the pressure within the skull, and was shown to occur by the late Sir Victor Horsley when a bullet was fired into the skull. By pole-axing the skull is opened, and it is therefore unlikely that inhibition of the heart should result. After the shooting or pole-axing of an ox the lower nerve centres may be, and generally are, destroyed by the insertion of a can or wire. This destroys the vaso-motor centre and relaxes the muscles. The blood by either of these methods cannot, therefore, be emptied out from the body so well as it is by the Jewish method.

When the brain of a small mammal is destroyed, as it can be instantly by the passage of a bradawl through the foramen magnum into the skull, it occasionally happens that the physiologist cannot keep the body alive by artificial respiration for the study of its functions. He then finds a clot formed in the right auricle of the heart It is probable that some damaged tissue—e.g., small fragments of bone—is in these cases carried from the venous sinuses of the brain to the heart, and there set up clotting. Such clotting would be more likely to happen in a shot than in a pole-axed animal ; if a clot forms in the heart bleeding is impeded.

Drawbacks of Pistol and Pole-axe.

It is clear, then, that the Jewish method of killing oxen is the best for draining an animal of blood. In Colombo, Ceylon, cattle are killed by throat-cutting after they have been fastened to tackle, whereby they are tilted into the head-down position so that the drainage of blood is complete. The machine carries the carcass on to the flayers, &c. By such means cattle can be killed, flayed, and cut up with great rapidity. Properly carried out, no better or more humane method can be devised. The pole-axe is not a certain method in the case of restive animals and in the hands of inexperienced slaughterers. The blow of the axe may sometimes miss the small area of the skull—about the size of a breakfast cup—which has to be struck. Missing this the pole-axe goes into the air spaces within the thick wall of the skull, and does not stun the animal. At Birmingham, in one case, the first blow brought the ox to its knees, but did not penetrate deeply enough to allow the cane to be used. It was then repeated. The long-armed pistol-killer of the R.S.P.C.A. appears to be a surer method of killing oxen. As in the matter of bleeding, the results of these two methods are not very dissimilar, the choice for oxen would then be with the pistol rather than the pole-axe. The free bullet is, however, not safe to use in slaughter-houses, and while the captive bullet is safe, it is difficult to use on restive or wild animals. An excellent method of slaughtering oxen is in use in Australia. Driven up an inclined path each comes finally to a small narrow enclosure with a window at the end. The ox lifts his head to look over, and a man standing above with a hammer at this moment stuns it. The ox falls, and is then carried down to the slaughter-house where it is hung up and bled. Breathing continues after stunning, so that bleeding is efficiently carried out. An ineffectual attempt to stun a pig with a hammer was made at Birmingham.

In the case of pigs, by fastening the animal head down and cutting the big arteries in the neck, blood and tissue and lymph are drained out by gravity, by convulsive respirations, and by general convulsive movements. When an animal is so bled, lymph passes from the tissues into the capillaries and veins in the effort of the body to keep up an effective circulation. The carcass of the pig thus bled, selected at Birmingham, showed firm dry flesh and firm white fat, and no blood could be squeezed out of the intercostal veins by running the finger along these. The shot pigs fell on the floor and were more or less convulsed ; in one case the convulsions delayed for three minutes the cutting of the throat. The effect of gasping respirations and gravity did not come into play. Hence the carcasses of the shot pigs showed moister flesh, pinker fat with blood in the vessels, and here and there small extravasations. It is obvious that such carcasses will keep less well and also be less fit for curing. The bacon curers say that the pig after shooting often falls with the hind feet so extended that the veins are ruptured, and large extravasations caused which make the hams useless for curing.

I took away the blade bone with some of the muscles attached to it from each one of the selected pigs. I placed a little of the muscle, taken from a similar part in every case, on a glass slide, flattened it out with a cover-slip and examined it under the microscope, using a low power. Blood was then seen here and there in the small blood-vessels and capillaries in the muscle and fat of each of the shot pigs. The muscle and fat of the pig bled in the ordinary manner, on the other hand, showed very little blood. The difference was clear also in sections of hardened and stained muscle. From the shot pigs, and one bled in the old way, I took 2 g. of flesh cut from the same part and minced it in each case in 20 c.cm. of water, and then froze and thawed the mince so as to break up the tissue and set the colour free. The coloured solution was then filtered. That of the pig bled in the old way appeared pale; that of one of the shot pigs was pinker; that of the other quite a deep pink. I examined each solution with the spectroscope and found hæmoglobin present. I then found how much water had to be added to each to make the characteristic bands of hæmoglobin almost disappear. Taking 3 c.cm. in each case I had to add 9 c.cm. of water, in the case of the pig bled in the old way 16 c.cm. in the case of one, and no less than 25 c.cm. in the case of the other shot pig. These results confirm what the naked eye observed, and the microscope showed; the muscle of the shot animals contained more blood.

Conclusion.

The butchers and bacon-curers are then right in their contention, and on the grounds of humanity, economy, and proper carrying out of a great business they should not be prevented from continuing the old methods of slaughter. These methods have been found right through ages of human experience. It is clear that bleeding is most rapid and complete in the head-down position, and I would urge that all pigs are killed in this position. A pulley and tackle can be used in any village. If a pig is stuck while standing up, bleeding cannot be so free or loss of consciousness so immediate. A chemist in the leather trade tells me that the quality of leather is lowered by the presence of blood in the hide; not only is the leather coloured by the blood, but suppleness is diminished. This is another point in favour of the method which secures most efficient bleeding.

QUO VADIMUS?

THE sustained interest taken by the general public in the course of nine public lectures just concluded by Prof. A. Dendy, F.R.S., on the Biological Foundations of Society is symptomatic of an age that is tending more and more closely to follow the progress of science. Among his audience was a very considerable sprinkling of clergy, and fitly enough, because the culmination of the lectures was a speculation from the zoological standpoint on the latter end of modern civilisation. The underlying basis was no new one. Individual species and civilisations have so far all followed the common trail—birth, youth, maturity, old age, death, a summary in fact of Shakespeare's seven ages, but Prof. Dendy examined whether there might not be a way out. There were, he argued, six problems urgently awaiting solution if modern civilisation was to escape the fate of its predecessors. The physical environment had to be ameliorated, the system of education had to be remodelled, the population controlled, the race improved by selection, the social organisation altered for the better, and the relations between the nations placed on a sounder footing. The most novel of the suggestions was that based on the view that man had to some extent superseded his physical by his mental environment, with the result that a vastly increased importance has been given to his mental images and emotions, and that this new mental environment now leads the way in progressive evolution, just as the physical environment did in the lower stages. On mental grounds, therefore, he advocated country life for early education and development, and for later education insisted on the importance of fostering ideas that were beneficial to mental and moral development, and repressing if not eradicating those of an opposite tendency. In dealing with the control of population he strenuously opposed teaching the masses of the people to restrict their families by means that seemed to strike at the very roots of self-respect and decency, and preferred the alternative solutions of a return to the land or emigration. For selection of the human race he looked to the progress of individual ideals rather than to any self-conscious State scheme, while warmly approving the policy of preventing the propagation of the feeble-minded. In discussing international relations he held that in view of the absence of physiological barriers and the breaking down of geographical barriers there should be erected strong moral barriers to prevent indiscriminate breeding, looking forward to the time when by division of labour each nation should coöperate in the interests of humanity as a whole. His concluding note was optimistic, to the effect that if modern civilisation should fail there was much in it of permanent value that would survive and serve as a foundation upon which future generations might build a more noble edifice.

A NEW CANCER CURE.

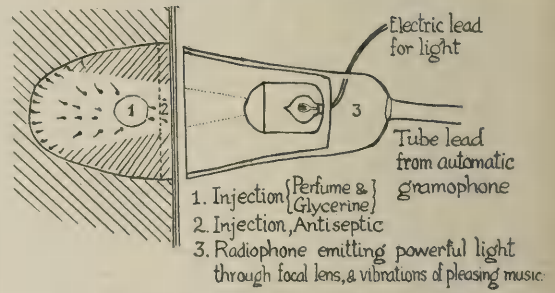
WE have received from the Director of the Imperial Cancer Research Fund the following account of a proposed treatment for cancer as submitted to him for publication. The document appended is exactly as it was received.

TREATMENT FOR CANCER.

Devised by Garnet B. Fawcett, A.R.A.S., Professor of Astrology, Aqualogy, Physiology, Dietics, Hygiene, etc., etc., etc.

Points to Remember.—(1) The germ is the equal of a serpent; (2) Serpents can be Charmed, Attracted, or Diverted by (3) Perfume, Sweets, Music, Light.

Treatment.—Diet and Salt the Body to give all the resistance possible to the germ. Inject to nearly the center a quantity of Glycerine impregnated with a powerful *Natural Perfume* (not Synthetic) (see No. 1 in Sketch). Then just beneath the Skin inject a powerful non-irritant Antiseptic (see No. 2 in Sketch). Then apply the Radiophone (see No. 3 in Sketch).



Electric lead for light
1
2
3
Tube lead from automatic gramophone
1. Injection {Perfume & Glycerine}
2. Injection, Antiseptic
3. Radiophone emitting powerful light through focal lens, & vibrations of pleasing music.

Action of Treatment.—The germ being held in check with the increased Salts in the body, will change its course and seek the Perfume and Glycerine, afterwards it will seek the Light and Music from the Radiophone and fall into the Antiseptic waiting for it. This treatment should be continued until the organism is exhausted of the germ, building up the Flesh behind it until the organism itself is ejected.

We agree that the cure presents distinctive features which make it unique among the many hundreds of suggestions which are submitted to the Imperial Cancer Research Fund for consideration.

WRIGHT'S IMPROVED PHYSICIANS' AND SURGEONS' VISITING LIST, 1924.

THIS list is now in its thirty-first year. The compiler, Dr. Robert Simpson, seems to have taken for his motto "Economy in space and time," for in a small compass—the book measures 7½ by 4 by ½ inch—is compressed a vast amount of useful information: diary, postal regulations, utero-gestation and posological tables, average heights and weights, poisons and antidotes, facts concerning the principal zymotic diseases, and so forth, while an ingeniously constructed visiting list enables the patient's name to be entered monthly instead of weekly, and the consultant's record enables him to see at a glance the date and hour of his appointment, together with the name of the medical man in attendance. In the visiting list one month is shown at an opening with space for receipts and payments. The obstetrical and vaccination engagement sections are equally well arranged, and space is also provided for motor-car expenses and memoranda. Well bound and printed on good paper, with a pencil within the flap of the cover, this list is ruled for from 40 to 240 patients, and the price varies from 10*s.* 6*d.* to 13*s.* A copy will be sent to any member of the medical profession on approval by the publishers, Messrs. John Wright and Sons, Ltd., Bristol.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

THURSDAY, Dec. 27th.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

FRIDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

Observations
ON
THE PARKINSONIAN SYNDROME IN LETHARGIC ENCEPHALITIS:
A PATHOLOGICAL POSTURE.*

BY IVY MACKENZIE, M.D. GLASG.,
VISITING PHYSICIAN, VICTORIA INFIRMARY, GLASGOW; PHYSICIAN TO THE MENTAL OBSERVATION WARDS, GLASGOW; NEUROLOGICAL SPECIALIST TO THE MINISTRY OF PENSIONS.

THE reactions of the human subject to the virus of epidemic encephalitis afford an excellent example of the general principle that however varied may be the sites of focal irritation or destruction of nervous tissue there is only a very limited number of ways in which the organism shows a response. It is difficult to imagine how so many lesions diffused through the series of basal nuclei which underlie the nervous integration of the body can find expression in manifestations characteristic for a single disease. And yet so it is; for although the signs and symptoms are admittedly protean, they combine as a whole to present a clinical picture which is typical for the illness.

The initial motor agitation bears only a superficial resemblance to that of chorea. It may vary from a series of tics affecting isolated muscles or portions of muscles of the head, trunk, or limbs, to rhythmic, undulatory, and coördinate gesticulations of the whole body resembling certain phases of hysteria. Myoclonus may be so violent as to render it difficult to prevent the self-infliction of bodily harm. Spasms of rotatory movement round the axis of the trunk may be seen either on the floor or under the bedclothes. Even where the behaviour is suggestive of chorea the phenomenon is distinct, in that by persuasion or by the attraction of attention it can be inhibited.

When to the peculiar agitation there is added paresis of cranial nerves—third, fourth, sixth, seventh, or twelfth—it is obvious that one is dealing with a process of a distinctive character. Implication of medullary structures is exhibited in disorder of respiratory, circulatory, or alimentary movement, as may be seen in isolated cases in spasms of rapid respiration, in others with bradycardia (pulse 40 per minute without heart-block), or tachycardia, and in still others with vomiting and profuse salivation.

CHARACTERISTIC SEQUELÆ TO LETHARGIC ENCEPHALITIS.

The sequelæ in which the nature of the disease may be disclosed for the first time are even more characteristic than its initial stages. For descriptive purposes these might be regarded as belonging to two classes according as they affect children on the one hand, and adults on the other. In considering this aspect of the problem one is naturally confined to the late effects of the earlier epidemics. In the case of children who have retained a legacy of the original disease the main disorder consists in profound emotional instability with perversion of conduct. Ebullitions of excitement, with uncontrollable impulse, manifesting itself often in outrageous and criminal conduct, would appear to afford the evidence of a serious dissolution of nervous integration effected in the earlier stages of the disease. Even in the most extravagant forms of misconduct there is rarely any clouding of the perception such as one finds in epilepsy, for when the spasm has subsided there is clear recognition of what has happened, and often an expression, even a precocious expression, of regret. After two or three years of illness one frequently finds no abatement of mental activity so far as intelligence is concerned, although, of course, organised mental development would appear in some cases to have been brought to a standstill by the incidence of the disease. The peculiar character of the sequelæ in children is probably determined by the fact that the disease has supervened during the early developmental period, and that neural dissolution has occurred before the organism has had an opportunity of establishing cerebral stability. Normal organic growth depends on the harmonious development of correlation between the basal centres which control the expressions of the grosser emotions and the cerebral centres which constitute the structural basis of perception and will-power. It is conceivable that extensive destruction of basal structures would lead to results in children quite different from those to which it would give rise in adults.

In adults in whom the early stage of lethargy was survived there was frequently a period of sleeplessness and restlessness, but there was no general tendency to the exhibition of those aberrations of conduct which lend such a distinctive colouring to the late effects in children. It has transpired, however, that some cases have acquired a relic of their own no less peculiar in its general characteristics than the impulsive restlessness of the younger victims. This relic or sequela of encephalitis in adults is described as a "Parkinsonian syndrome," on account of its alleged resemblance to paralysis agitans. A considerable literature has already appeared on the subject, and the descriptions of different observers in various countries bear testimony to the uniformity of the nature of the disability. General muscular rigidity, masking of the expression, relative immobility of the eye-balls, fixation of the head on the shoulders, restriction of movement, and especially of rotatory movement in joints, comprise in varying degrees the almost invariable features of this condition. Tremors in some cases, and especially in the hands, lend an aspect which suggests the resemblance to paralysis agitans. Propulsion or retropulsion is not present to the degree which might be expected from the facial expression and general rigidity, and the practically constant presence of inordinate salivation justifies a doubt as to its affinity to the syndrome with which it has been compared.

To those accustomed to view an illness from the point of view of the attitude, posture, or behaviour of the organism, it must have occurred that while the by-product in children is an expression of aberrant psycho-motor excitement, that in adults is closely akin to catatonia. It is, however, a catatonia without stupor, although in some cases there is a certain degree of psycho-motor retardation. This important aspect of the problem has received but very fragmentary attention in current accounts; but it cannot be dealt with here, as it is our purpose to consider a more limited but equally interesting side of the question—namely, the organic basis of the so-called "Parkinsonian syndrome."

ORGANIC BASIS OF THE PARKINSONIAN SYNDROME.

What strikes one most forcibly about a series of these cases is the extraordinary constancy of the appearance they present. The staring eyes with an expression of fear or of wonder emphasised by the immobility of countenance, the fixation of the head on the shoulders in erect posture, and the rigid attitude of the body as a whole, gliding rather than walking, are features which suggest the characters of a lay figure. In turning round the body turns as a whole. Rotation of one part of the body on another cannot take place in sufficient time to give the impression of coördinate or natural agility. A disability of this character and extent must be associated with a very widespread depression of neural function. If it depends immediately or remotely on a localised lesion, that lesion must be situated at important centres of nervous integration. The early choreiform movements and the late rigidity resembling paralysis agitans have been responsible for the suggestion that the lesion may be found in nuclei in the base of the cerebrum. Little is known, however, about the function of these nuclei in health and in disease, and the evidence as to their mode of action is somewhat contradictory. On the other hand, there is very definite evidence that nuclei in the mid-brain, pons, and medulla are involved in the acute processes of the early stages of encephalitis, and the clinical evidence of such involvement has been correlated with post-mortem findings. Ophthalmoplegia, facial and hypoglossal paresis, respiratory disorder, profuse salivation and trigeminal neuralgia are frequent symptoms in the initial stages, and they are symptoms whose anatomical basis can be interpreted in the light of the function of nuclei whose physiological action is generally recognised.

---

* Made under a grant from the Medical Research Council.

Although the Parkinsonian syndrome does not at first sight appear to depend on involvement of these nuclei, it does very forcibly suggest the implication of a neural system in the base of the brain to which some of them at least are closely related. This system is known as the *median longitudinal fasciculus.* According to Elliot Smith,[1] it consists of—

> "a very conspicuous tract of longitudinal fibres which extends throughout the whole length of the medulla oblongata, pons, and mesencephalon, in the formatio reticularis or tegmental part of each. Below, at the level of the decussation of the pyramids it becomes continuous with the fasciculus anterior proprius of the spinal medulla, whilst, by its superior or opposite end it establishes intricate connexions in the region immediately above the mesencephalon. Throughout its whole length it lies close to the median plane and its fellow of the opposite side. In the mesencephalon it is applied to the ventral aspect of the central grey matter, whilst in the pons and medulla oblongata it is situated immediately subjacent to the grey matter of the floor of the fourth ventricle. One of its most salient features is the intimate association which it presents with the three motor nuclei from which the nerves for the supply of the muscles of the eye-balls take origin—viz., the oculo-motor nucleus, the trochlear nucleus, and the abducens nucleus. The first two of these are closely applied to its medial and dorsal aspect, while the abducens nucleus is placed on its lateral side. Into each of these nuclei it sends many collaterals, and probably also some of its constituent fibres, and these end round the nuclear cells. It would appear, therefore, that one of the most important functions of this strand is to bind together these nuclei and thus enable them to act in harmony, one with the other. Fibres also enter the median longitudinal fasciculus from the vestibular nucleus of the acoustic nerve system. The result obtained by degeneration would seem to indicate that to a large extent it is formed of fibres which run a short course within it."

The cephalic end is extremely complicated, and is believed to have relation to the globus pallidus and to nuclear centres in the posterior commissure (Muskens).[2] Into its composition there are said to enter also fibres from the cortico-bulbar tract to the oculo-motor nuclei. Whatever modification it may have undergone in its functional reaction as the result of cerebral development, it is essentially a system of great antiquity and of great neural stability. It has a phylogenetic history coincident at least with the evolution of vertebrate life. In fishes, amphibians, and reptiles it is one of the largest bundles of the medulla oblongata ; and in man its fibres acquire their medullary sheaths between the sixth and seventh month of fœtal life, and at the same time as the fibres of the fasciculus anterior proprius of the spinal medulla with which it stands in connexion.

With the transference of the spinal accessory nerve from visceral to somatic innervation the median longitudinal fasciculus enters into relation with the nucleus of that nerve in its control over the muscles which regulate the movements of the head on the trunk. Here, then, is a common neural system, comprised of two long fasciculi and containing a variety of fibres, which binds in integral relationship the motor nuclei which govern the conjugate movements of the eyes and the complementary coördinate movement of the head on the trunk. It is feasible to suggest that this system is in some way associated with the phenomena of the Parkinsonian syndrome, for its activity is admittedly connected with those movements which in this disability are laid under restraint.

Posture or attitude is the dominating feature of the clinical picture. Muscular rigidity is the sign of the disease. There is no muscular wasting, no motor paralysis, and the tendon reflexes are present, and are relatively more brisk on the side which is more rigid when two sides of the body are affected in different degrees. Although there is hypertonicity, there is no spasticity. The defect is obviously one associated with muscular innervation, and yet both the upper and lower motor neurones appear themselves to be intact.

In discussing the wider combination of reflexes in the production of coördinate movement, Sherrington[3] points out that—

> " the motor neurones of a muscle of the knee are the terminus ad quem of reflex arcs arising in receptors not only of its own foot, but from the crossed fore-foot and pinna, and tail also undoubtedly from the otic labyrinth, olfactory organs, and eyes. Thus, if we take as a standpoint any motor nerve to a muscle it consists of a number of motor neurones which are more or less bound into a unit mechanism ; among the reflex actions of the organism a number can be brought together as a group because they all in their course converge together upon this motor mechanism, the final common path, activate it, and are in harmonious mutual relation with regard to it. They are in regard to it what were termed above 'allied' reflexes."

The problem of the functional activity of the motor neurones concerned in this syndrome should be approached in the light of this conception. The compendium of neural elements which comprise the median longitudinal fasciculus binds into a harmonious mechanism the motor nuclei to the extrinsic muscles of the eyeballs (third, fourth, and sixth), the motor nuclei for the muscles of the neck (eleventh, &c.), and through the fasciculus anterior proprius the motor nuclei in the anterior cornua of the cord. The fibres of the fasciculus may be regarded as the connector portions of reflex arcs converging on the motor nuclei whose internal arrangements constitute the motor mechanisms for the muscles they supply. Now the fasciculus itself is a tract which is common to a variety of arcs emerging from various sources, and in virtue of the peculiar properties of these sources exercises a determining influence on the activity of the motor mechanism on which they impinge. (1) Stimuli enter the fibres of the fasciculus through its complex origins from the superior colliculus, posterior commissure, and globus pallidus. (2) The influence of the cerebral cortex is exercised through the cortico-bulbar tract, some of whose fibres are said to join the fasciculus, while other oculo-motor fibres from the cortex enter the nuclei directly. These fibres are motor in the sense that they originate in the cells of the motor cortex, but they are afferent in respect of their relation to the lower motor neurones. (3) Stimuli from the visual apparatus enter the fasciculus through the mid-brain, and from the fasciculus are distributed to the motor nuclei. (4) Fibres from the vestibular nucleus (Deiters') join the fasciculus to be distributed to the motor nuclei, and in addition to these other fibres find a course through the vestibulo-spinal tract to the motor nuclei in the cord.

Coördinating Function of Median Longitudinal Fasciculus.

It is thus evident that the fibres of the median longitudinal fasciculus and related structures have a very varied origin, but they have this in common that they combine in their various ways to exercise a coördinating influence, not merely on individual motor nuclei, but on a series of motor nuclei which operate in a mutually harmonious fashion for a definite purpose. The question then arises whether it is possible by examination of the contributing sources to detect any abnormality which might indicate a faulty reaction of the mechanism, of which the median longitudinal fasciculus constitutes a consolidating element. The following information is available : (1) The neural connexions of the cephalic end of the fasciculus have not been sufficiently defined to warrant their consideration in a clinical interpretation ; (2) there is no evidence, in the cases examined, of disease of the motor cortex or of upper motor neurones ; (3) the visual apparatus is normal ;

(4) examination of the vestibular apparatus in a series of cases showed in a majority of these an abnormal reaction, and the degree of abnormality was proportionate to the gravity of the general disability.

The following record of a typical case illustrates the course of development of the disease and the present clinical state :—

CASE 1.—A single woman, aged 32, who had previously enjoyed excellent health, took ill on May 20th, 1920, with sickness and vomiting. This lasted for a week, during which she slept normally, and had no other symptoms. A pain then began at the back of the right ear, and she had a sensation in her face as if it were being squeezed. Coincident with the onset of pain, the right side of her face and right arm began to twitch; this continued for ten days, during which she was sleepless. She then passed into a delirium, which lasted other ten days. She has a vague recollection of suffering pain during the delirium. Following the delirium she had diplopia which lasted a week. During the following six months pain in the head and right arm was persistent and she never had a good night's rest, although she sometimes slept during the day. Her general condition, however, gradually improved; the pain became less, and on Dec. 12th, 1920, she resumed her work. From this time till August, 1921, she enjoyed comparatively good health, although the pain in the head and arm never completely disappeared, and she suffered occasionally from peculiar feelings in the arms and legs "as if something was working in them." In August, 1921, she noticed a stiffness in her neck, arms, and legs. This was most profound in the left arm to begin with, and it gradually became worse till she was compelled to give up work in December, 1921. Since then the stiffness has increased, more particularly on the right side, and there has been a tendency to profuse salivation. A remarkable feature in her condition is that since the onset of the rigidity the headaches have disappeared, although the pain in the shoulder and arm still remains.

Later State.—On March 19th, 1923, but for a slight tremor of the right hand, she looked, when standing in the erect position, as if she were petrified. The eye-balls were fixed, the expression was in statue-like repose, the head erect and stationary, the right shoulder slightly elevated and retracted, the arms were slightly flexed at the elbows, and the hands slightly flexed, almost meeting in front. She progresses along the floor like a mobile mass. The movement of sitting down was carried out under inhibition, and further examination shows that if the buttocks were as rigid as the shoulders, to sit would be impossible. The rigidity was more intense in the cephalic than in the caudal end of the body. The right shoulder was more rigid than the left, and the shoulder-joints were more firmly flexed than those of the elbows or hands. Rotation was defective in the joints of the limbs as well as in those of the neck. The tendon reflexes were exaggerated, and relatively more so on the side on which the rigidity was more pronounced. There was tenderness on pressure over the back of the neck and on the shoulder on the right side. There was less tenderness on pressure of the right elbow and no tenderness on pressure of the right wrist. The tongue was tremulous and was protruded with difficulty, but apart from excessive salivation the visceral systems appeared normal, and menstruation was regular. Mentally she was quite clear, and her memory was excellent. She was extremely anxious to become well, although the effort to help herself appeared to impeded by a sense of hopelessness and despair. She was emotionally unstable and wept on slight provocation. The pupils were unequal, the right being smaller and less reactive to light than the left; both pupils reacted in accommodation; there was no squint or defect of vision or of hearing. Examination of the vestibular apparatus by the caloric method and by rotation on a Bárány chair showed an absence of nystagmus, of vertigo, of falling, and of past pointing.

One is dealing here with a state of pathological posture immediately due to muscular hypertonicity. There is no paralysis except in so far as movement is restricted by abnormally increased tonus. There is obviously a disturbance of nervous equilibrium in favour of processes which induce muscular tonus.

The following summary in the first eight cases examined applies generally to the results of the examination of the vestibular reaction in a series of 32 cases. The cases are arranged in order according to the severity of the muscular rigidity. There was little difference in this respect between each of the first four, but there was more rigidity in the first four than in the last four. In Case 8 the vestibular reactions were practically normal, although the patient exhibited in a mild degree the expression and gait characteristic of the syndrome. The first four were completely incapacitated by the rigidity; the last four were able to go about and help themselves to some extent. Cases 5 and 7 are specially interesting in that while ocular movements could be induced by the caloric test and by rotation, there was no vertigo, falling, or past pointing, and the patients walked straight from the Bárány chair without reeling or stumbling. The results of the caloric tests may be summarised as follows :—

(*a*) *Nystagmus.*—(1) Absence of nystagmus to caloric test in four cases out of eight (Nos. 1, 2, 3, 4). (2) Diminished or delayed in one case (No. 5). (3) Diminished in one eye and absent in the other in one case (No. 6). (4) Normal in degree, but abnormal in direction in one eye in one case (No. 7). (5) Normal in both eyes in one case (No. 8).

(*b*) *Vertigo.*—(1) Absent in four cases (Nos. 3, 4, 5, 7). (2) Present in four cases (Nos. 1, 2, 6, 8).

(*c*) *Falling.*—Subjective and objective falling absent in those cases in which vertigo was absent (Nos. 3, 4, 5, 7).

(*d*) *Past Pointing.*—Absent in all cases except one (No. 8).

A number of interesting clinical points have been passed over in the attempt to focus attention on the involvement of the proprioceptive system, for this would appear to afford the most favourable means of interpreting the conditions of neural dissolution which underlie the syndrome. The vestibular tests, however, present a paradox which invites further inquiry. The absence of a vestibular reaction is not at first sight consistent with muscular hypertonicity. Destruction of the vestibular apparatus is followed, as a rule, by loss of muscular tone on the side of the lesion. Consideration will be devoted later to the nature of the disturbance of the proprioceptive system which is consistent with insensitiveness of the vestibular apparatus and abnormal increase in muscular tone in one and the same subject.

CLINICAL PICTURE OF LETHARGIC ENCEPHALITIS.

Attention has been called already to the fact that notwithstanding the widespread distribution of inflammatory reaction in the early stages of lethargic encephalitis, the clinical picture is one which is, generally speaking, typical for the disease. Through the maze of reactive phenomena incident to multiple foci of irritation there may be noted signs and symptoms which, when taken as a whole, are characteristic expressions of one morbid process. This, at any rate, applies to the average case which comes under the care of the hospital physician, although it is quite possible, and even probable, that there are instances in which the infection is so mild and transient as to elude recognition. It is quite otherwise, however, with the Parkinsonian syndrome, a residual legacy of the initial disorder. Here there is no evidence of those fleeting disorders which at one time take the form of motor agitation, and at another the form of paralysis, delirium, lethargy, or sleeplessness. It may be the evidence of a neuronic irritation, but it does not suggest a recrudescence of the infection in its original form; yet neither does general paralysis, although it is an expression of infective activity. As a rule it makes its first appearance at varying intervals after the curtain has been lowered on the phantasmagoria of the earlier scenes. It commences gradually; it progresses steadily; and there would seem to be a method in the manner in which one part of the body after another is brought under the restricting influence of muscular hypertonicity. In the earlier stages and in milder cases the cortical motor power would appear to be able to overcome the resistance, but in the more advanced stages the contraction increases till the patient would seem to be held in a muscular vice.

EXTENT OF INVOLVEMENT OF MECHANISM OF EQUILIBRATION.

If the results of the vestibular tests warrant the assumption that the syndrome is due to an abnormality of the mechanism of equilibration, the question naturally arises whether or to what extent that mechanism is involved in the acute inflammatory stage of the disease. Microscopic examination of the brain in fatal cases reveals a very extensive infiltration and destruction of nervous tissue, more particularly in the basal structures. But there is no such predilection for special areas as would justify the assumption that the late effects are the direct results of local lesions. The uniformity of the clinical picture with its typical delineation from case to case suggests that the syndrome is the expression of abnormal reaction on part of some important compendium of reflexes. One is dealing not so much with the immediate results of neuronic destruction and neural dissolution as with the delayed and remote reaction of structures whose function in the harmony of nervous integration has been impaired. The syndrome supervenes after an interval of apparent recovery. It is not of the nature of a genuine recurrence, for it is not accompanied by any of the phenomena which distinguish the onset of the disease. Nevertheless a link does exist. If the absence of vestibular reaction possess the ætiological significance it would appear to indicate, then one might expect to find in the early stages of the disease some clinical evidence of disorder either of the apparatus itself or of some of the structures to which it is closely related. The vestibular tests during the acute phase show in some instances—e.g., Case 2—an exalted reaction. Giddiness, sickness, and nystagmus may be even spontaneous when the patient assumes a particular posture and disappear when that posture is changed. But these symptoms appear without any affection of hearing, and it is highly improbable that the vestibule and semi-circular canals could be the site of an inflammatory process which did not at the same time involve the cochlea. If, however, the receptor organ is not affected, the disturbance must be relegated to the important nuclei of correlation in the pons and medulla which subserve the functions of the peripheral apparatus. These nuclei are the secondary or terminal nuclei of the vestibular nerve (the primary neurones are on Scarpa's ganglion on the course of the nerve in the petrous bone). They occupy an extensive area of the rhomboid fossa (area acoustica) and extend as far forward as the caudal border of the main sensory nucleus of the trigeminal nerve, and as far backward as the rostral extremity of the nucleus gracilis. These central cellular masses of terminal neurones are described anatomically as divisible into four main nuclei: (1) Dorsal, median, or principal nucleus; (2) inferior spinal or descending nucleus; (3) superior or Bechterew's nucleus; and (4) lateral or Deiters' nucleus. Into these nuclei and into the cerebellum stimuli are poured from the reception terminals in the labyrinth. In the nuclei the stimuli are correlated and distributed according to their appropriate destinations and the functions they are supposed to perform. Fibres pass from the nuclei (1) to the motor nuclei in the brain-stem and to the anterior cornua of the cord through the vestibulo-spinal tract; (2) to the motor nuclei for the ocular muscles through the median longitudinal fasciculus; and (3) to the reticular formation of the opposite side across the median raphé. The nuclei themselves lie in close proximity to important medullary and pontine centres. On their medial aspect in front is the trigeminal nucleus, while more caudally lie the nuclei of the facial, glossopharyngeal, and vagal nerves. Their position in the brain-stem is therefore such that should they become the seat of pathological reaction, that reaction is likely to involve at the same time nervous centres which are concerned with the regulation of the vegetative systems of the organism. It is likewise reasonable to suppose that disorder of the vegetative centres, whether of an irritative, toxic, or inflammatory character, may also implicate the neighbouring nuclei of the vestibular apparatus.

There is, as a matter of fact, conclusive evidence that in the early and acute stages of lethargic encephalitis the vestibular and also the neighbouring nuclei participate in the production of the morbid phenomena. In the following case the clinical signs and symptoms could be ascribed, for the most part, to disorderly function of the vestibular nuclei.

CASE 2.—On March 21st, 1923, a married woman, aged 48, with previous good health, was seized suddenly with severe pain in back of neck and shoulders; power appeared to leave her legs; she fell to the ground and became very sick; vomiting and retching persisted for some hours, and when these symptoms ceased the pain became localised to the head and was so severe as to prevent sleep. Even pressure of head on pillow sufficed to elicit tenderness. On the following day there was twitching of muscles of face and neck. About 36 hours after onset of illness diplopia appeared, and there was an external squint on left side. Photophobia present during the first few days. There was no delirium. The temperature, 103° F. on the second day, subsided gradually in the first week. Giddiness has been a constant feature, and has been noted more particularly in certain positions. After the first few days she slept normally, and after regaining her sleep there was no pain.

Condition on Admission.—She was admitted to the Victoria Infirmary, Glasgow, on the 29th, when her only complaint was of giddiness and sickness, the symptoms appearing only when she lay on left side. Apart from an external squint in the left eye and twitching of the eyelids, nothing abnormal was noted.

On April 3rd, quite comfortable so long as she lay on her right side; still a squint and flickering of the eyelids; no paralysis or sensory disturbance; hearing, sight, and temperature normal. No visceral disorder, but as soon as she turned on her left side she felt very giddy and imagined that objects were turning from right to left. This was associated with spontaneous nystagmus to the right. On turning on to her back or right side, giddiness and nystagmus disappeared. Cold water in the left ear, while she lay on her back, produced in seven to ten seconds nystagmus to the right. It increased in intensity after cessation of the stimulus and was accompanied by severe giddiness and sickness. Nystagmus to the left from cold water in the right ear occurred in 30 to 35 seconds.

Had this illness not occurred at a time when encephalitis was epidemic, legitimate doubt might have been cast on the diagnosis. Such doubt, however, may be regarded as dispelled by consideration of the nature of the associated phenomena. The main feature of the condition, that is to say, the giddiness, sickness, and nystagmus, might quite well have been due to a hæmorrhage into the vestibular apparatus. The sudden onset with collapse and headache might have been explained on this assumption also. But when to these expressions of disease were added the squint and diplopia, the twitching of the facial muscles, the febrile disturbance lasting for the most part of a week, and with these the absence of any affection of hearing, the conclusion was justified that the pathological process involved the vestibular nuclei in the brain-stem. This conclusion was further confirmed by the abnormally sensitive character of the vestibular reaction to the caloric and postural tests.

The following case illustrates some of the peculiar phenomena which characterise the more severe forms of the disease in children. In the course of its development the reaction passes into a phase which suggested an affinity to the Parkinsonian syndrome in adults.

CASE 3.—H. M., a well-developed and intelligent although nervous lad, aged 14, had good health till Feb. 16th, 1923, when he complained of pain in the right shoulder, radiating up the right side of the neck to the right ear. The pain was severe and persisted during the course of the day. In the evening his parents noticed intermittent twitching of the right eye-lid, and later on the right side of the face. He spent a sleepless night, and on the following day spasmodic contractions of the facial muscles were more profound and almost continuous. Irregular grimacing contortions of the face were accompanied by jerky opening of the mouth and protrusion of the tongue. At night his voice was hoarse, and he became delirious and raved about Germans and bombs, and appeared to live through incidents he had witnessed in picture-houses. On the 18th the whole of the right side was affected, and he tossed himself about in bed, assuming extraordinary attitudes. He bit and tore the bedclothes, turned his pillow time after time, and got in and out of bed. Another restless delirious night was spent partly in shouting and partly in singing pieces of songs.

Condition on Admission.—On the 19th he was admitted to the Victoria Infirmary. Both sides of the body had now become involved in the motor agitation, and he was in a state of acute delirious excitement. At one period on the day of admission he appeared to suffer from fleeting hallucinations of different kinds. He was restrained in bed with difficulty. He wept, laughed, shouted, and sang alternately, and in his quieter moments he prayed "give me strength to kill my oppressors." For two days and two nights he remained in this excitable state; only occasionally during that period was it possible to obtain from him rational response to questions. It appeared as if the spasms of excitement occurred in phases with short intervening intervals in which he was comparatively lucid.

Course of Case.—On the 22nd he became more restful. The delirium passed off; the jerky, irregular movements continued, and he muttered in an incoherent manner, but his attention could be held with ease, and he answered simple questions intelligently and was well orientated in time and place. When his attention was held it was possible to induce cessation of the movements. An internal squint on the left side had now appeared, and he had diplopia. The temperature, 101·2° F. on admission, had gradually returned to normal. Apart from the involvement of the ocular muscle there was no evidence of paralysis, and sensation was normal. He remained perfectly quiet during the day, but at night he again became restless and delirious, although not to such an extent as on the previous nights. There was no complaint of pain since the day of the onset of illness.

On the 24th he was much quieter. The motor agitation had almost completely gone. He fed himself and was able to answer questions clearly, although somewhat slower than normal. His expression was dazed. He was inclined to be lethargic, and lay, for the most part, on his face. At night he was restless, turned the pillow about from time to time, and occasionally got out of his own bed and attempted to get into those of his neighbours. The squint and diplopia persisted, and there was spontaneous nystagmus to the right. His cerebro-spinal fluid was normal.

On March 12th he had gradually become quieter, and, although never in a deep lethargic state, slept for considerable periods during the day and night. His face had assumed a masked expression. He was cataleptic. Mentally he was quite clear, and there had been no sign of stupor or of other nervous disorders usually associated with catalepsy. His pulse, which varied from 70 to 90 per minute during the earlier stages of the disease, had varied from 50 to 60 per minute during the previous week, and on that day was registered at 40 per minute. There was no heart-block, and the circulatory system seemed to be normal in other respects. The catalepsy was associated with hypertonicity of the muscles.

On the 18th the cataleptic state persisted, and there was no mental abnormality. Patient slept well; squint still present; rapid, jerky movements of eye-balls as soon as eyes passed the middle line on either side. The periods during which these movements lasted varied from day to day and from time to time during the same day. They might last from 2 seconds to 20 seconds, and their rate appeared to be between 200 and 300 per minute. There was partial double ptosis, and the right pupil was wider than the left. Both pupils reacted to light and in accommodation; fundi normal; deep reflexes exaggerated; no sensory disturbance.

On the 30th the condition had varied but little since the 18th. The jerky movements on deviation of the eye-balls had diminished, and lasted but one or two seconds. At times there was only a slight flicker. The expression was still marked. There was a lack of ease and agility in his movements, and he was still cataleptic.

On April 5th there had been for three days no spontaneous nystagmus. The expression, however, was still masked. Patient dull, cerebration slow although quite clear; squint present. Cataleptic posture not so well sustained; definite catatonic resistance and rigidity in left lower limb; deep reflexes were exaggerated. So long as spontaneous nystagmus was present it was considered inadvisable to make vestibular tests. These tests now failed to reveal nystagmus by the caloric method.

Whatever may be the ultimate outcome in this particular case, there can be no doubt that already in the early weeks of the disease it exhibited not only an involvement of the structures related to the vestibular apparatus, but also a state of abnormal tonus akin to that which characterises the Parkinsonian syndrome.

While these two cases are selected from a series of 15 in order to demonstrate the occurrence of vestibular phenomena in the incipient phase of the disease, a review of the prominent signs and symptoms in the whole series indicates that these phenomena are by no means unusual. Thus, diplopia or squint was present in 14, spontaneous nystagmus in four, giddiness in five, revolving on the longitudinal axis of the body in three, and incoördinate motor agitation (including choreiform movements (six), twitchings (seven), and coarse general tremors (two)) in 15. Signs and symptoms referable to the nuclear centres in close proximity to the vestibular nucleus were noted as follows: Trigeminal neuralgia in six, vomiting in six, rapid respiration in five, slow pulse in two, rapid pulse in three, pain in neck and shoulder in five. There has been no opportunity to correlate the earlier with the later clinical features of the Parkinsonian cases, and attention has been directed to the vestibular phenomena in the recent epidemic in view of the fact that the labyrinthine tests in the sequelæ were a subject of observation at the time of the outbreak.

PATHOGENY OF THE PARKINSONIAN SYNDROME.

Two leading questions suggest themselves in considering the pathogenesis of a syndrome of this kind; these have reference to (1) the site and the character of the structural changes underlying the reaction; and (2) the nature of the perverted physiological processes responsible for the uniformity of the clinical picture.

(1) To the first question no satisfactory answer has been offered. This is not surprising when one considers the great variety of structural changes which have been described in paralysis agitans. In this condition regressive changes have been described in the corpora striata, thalami, substantia nigra, pons, and medulla. These admittedly are sites in which the lesions in acute encephalitis are found. But pathological degeneration of the same structures in other diseases does not give rise to clinical states which have a resemblance to the Parkinsonian syndrome. An instructive analogy may be found in general paralysis of the insane, a disease due to the particular manner in which a specific virus attacks the nervous system. Here also the uniformity of the clinical delineation from case to case is associated, not with any localised lesion, but with neuronic and vascular degeneration in the tissues of both the forebrain and brain stem. We have examined a number of brains from acute and from chronic stages of encephalitis, and the lesions have been so diffuse and so widespread as to preclude the possibility of formulating a specific correlation between the anatomical abnormality and the clinical disorder of function. Infiltration and degeneration of the vestibular nuclei (although accompanied by lesions elsewhere) have nevertheless been observed in several instances.

(2) It is no reflection on the value of histological investigation to suggest that the attempt to find an anatomical basis for clinical phenomena is often responsible for hasty and ill-considered conclusions. It is only on some occasions that it is possible to bridge the gulf between degenerate tissue and abnormal organic reaction by a process of satisfactory reasoning. In such well-recognised conditions as chronic heart disease, chronic nephritis, or general paralysis of the insane, the pathologist and the clinician are able to recognise the abnormal process each from his own point of view; there may be complete agreement between the two as to the concurrence and interdependence of the anatomical and clinical states, but the nature of the association between the states is usually a matter of conjecture.

In the Parkinsonian syndrome, the outstanding features of organic behaviour are the attitude of the patient, the muscular rigidity, and the impediment of voluntary movement especially of a rotatory character. In the absence of evidence of involvement of the cortico-spinal tracts attention is attracted to the complementary proprioceptive system. Examination of the vestibular apparatus shows that in a proportion of cases there is evidence of interference with the normal processes of somatic equilibration. The extent of abnormal reaction to the caloric and rotation tests seems to bear some relation to the degree of rigidity.

The significance of the vestibular tests may be estimated in the light of the principle of "associated phenomena" expounded by Mackenzie in his interpretation of the signs and symptoms of disease. The associated clinical phenomena in this problem may be divided into (*a*) those which are directly related to the system of equilibration, and (*b*) those which are related to nervous structures which lie in immediate proximity to the vestibular nuclei in the pons and medulla.

(*a*) There can be no doubt that in the acute phase of many cases of encephalitis the nervous structures which subserve equilibration are affected. Diplopia, squint, nystagmus, giddiness, rotatory movement, catalepsy without stupor, are all evidence of this. The absence of any affection of hearing precludes the likelihood of involvement of the internal ear, and the signs and symptoms are not such as are usual in disease of cerebellar origin. There is thus justification for supposing that the disorder is expressive of abnormal reaction on the part of the proprioceptive system which is represented in the vestibular nuclei of the medulla and pons.

(*b*) The associated clinical phenomena which have no reference to equilibration confirm this suspicion. The intensive trigeminal neuralgia, sometimes in the eye or in the ear or in the teeth, which marks the onset of the disease is probably due to affection of the trigeminal nuclei which lies in close relation to the vestibular nuclei. Respiratory disorder and vomiting may be referred to abnormal reaction of a compendium of medullary reflexes which is also in close relation to the vestibular nuclei. Excessive salivation, which is one of the most constant and most prominent signs of the Parkinsonian syndrome, must be associated with irritation of the salivary nucleus which lies also in close proximity to the vestibular nuclei. The tremor of the tongue, the defect in mastication and swallowing, and the lack of expression in phonation, are probably a local expression of the general motor disability, although they are so pronounced in some cases as to suggest a special implication of the pons and medulla.

If there is any justification for regarding the vestibular nuclei and their associated reflex arcs as a mediating centre in the production of the Parkinsonian syndrome, the question arises as to the manner in which they participate. The vestibular nuclei comprise the secondary or terminal neurones of the vestibular apparatus. They bear the same relation to the vestibular portion of the internal ear as do the trigeminal nuclei to the skin and mucous membranes supplied by the fifth nerves. They are the centres of correlation for stimuli induced in the internal ear through movements of the body in space, just as the trigeminal nuclei are centres of correlation for stimuli of exteroceptive origin impinging on its area of distribution. The fifth nerve has to do with the conduction of stimuli for touch, pain, heat, and cold, while the vestibular nerve is concerned exclusively with the conduction of stimuli which induce a state of muscular tonus indispensable to the maintenance of somatic equilibrium. Under physiological conditions the trigeminal nucleus is stimulated from the mucous and cutaneous surfaces of the head; but it may be, and usually is in pathological states, subjected to irritation of central origin. For example, the headaches of fever, migraine, epilepsy, neurasthenia, and biliary colic are associated with either toxic or excessive irritation of the trigeminal compendium, and the site of stimulation is not the periphery but the central or terminal nuclei in the medulla and pons. There is no necessity to labour this point in demonstration of which a great mass of clinical evidence could be adduced. There is reason to believe that the vestibular nuclei may also become "foci of irritation" (Mackenzie) or sites of abnormal reaction from stimuli which impinge on them, not from the vestibular apparatus but from sources of central origin. The frequent occurrence of headache and vomiting with giddiness is indicative of the proclivity of medullary centres to become the seat of aberrant irradiation of neural stimuli in whose clinical manifestations reaction of the vestibular nuclei plays an important part. Giddiness is only one of the by-products of abnormal vestibular recoil; it is the resonance in consciousness of the irregular behaviour of vestibular structures which in the normal course of events make no appeal to the higher centres of the brain. The vestibular nuclei are the main centres of correlation of the afferent stimuli of the proprioceptive system; in this capacity they are in close functional relationship with the internal ear, the eyes, the cerebrum, the red nucleus, and the cerebellum. Hughlings Jackson and Sherrington have laid the clinical and experimental foundation of observations which show that this system contributes to the coördination of somatic movement by the influence it exercises on muscular tone. In the posture of post-hemiplegic and decerebrate rigidity it plays its rôle by the production of abnormal muscular tonus. It is suggested here that abnormal irritation of the vestibular nuclei and their associated structures is responsible for the pathological features of the Parkinsonian syndrome. This conception, while it explains the rigidity, accounts also for the increased salivation and for the absence and abnormality of vestibular reactions in the more advanced stages, in which stimuli from the ear cannot be correlated in nuclei which are already in a state of pathological activity. There is probably a close analogy between the persistent headaches which follow influenza and the rigidity which is so prominent a sequela of infective encephalitis.

I am much indebted to my colleague Dr. Hector M. Walker for his assistance in this research.

[Since this article was written an important communication on "Lethargic Encephalitis and Herpes Febrilis" has appeared, in *Brain*, by Syzmanowski and Zylberlast-Zand.[4] They find that "in animals (rabbits infected with emulsion from cases of lethargic encephalitis) the most common symptoms are abnormal position of the head, circus movements, nystagmus, and oscillating movements of the head, that is, symptoms of labyrinthine involvement." In their microscopic findings they note that "the rabbit No. 31 helped to determine the origin of the labyrinthine symptoms," so often met in their investigations. They say that "no inflammatory changes were discovered in the brain tissue except in the nucleus of the nervus vestibularis and in the tuberculum acusticum. The cells of the vestibular nucleus were degenerated. Slight changes were also found in the cells of Deiters's nuclei and in the nuclei of the floor of the fourth ventricle, but the cells of the cerebellum, red nuclei, and nuclei dentate were not affected."]

AN IMMUNITY REACTION IN SCARLET FEVER.*

By W. MAIR, M.D., B.Ch., B.Sc. Edin., D.P.H.,
RESEARCH PATHOLOGIST TO THE METROPOLITAN ASYLUMS BOARD.

In 1918 Schultz and Charlton[1] described the following phenomenon in connexion with scarlet fever (I give a free translation of their words): "If one injects intracutaneously into the skin of a scarlet fever patient with a bright rash 1 c.cm. of serum from a normal person, or from a convalescent case of scarlet fever, there appears, after a time, at the site of the injection, a characteristic change. This begins after about six hours, and consists in a complete blanching of the rash over an area of from half an inch to a few inches in diameter. The area of pallor is usually circular or oval in shape, the margin being as a rule only slightly irregular. In the affected area the swollen follicles, which are a feature of many rashes, disappear. Looked at from a little distance, the margin of the defect in the rash is generally pretty sharply defined. In one case we saw the contrast between the pale area and the surrounding rash heightened by a markedly hyperæmic margin. The colour of the blanched area is that of the normal skin. The duration of the phenomenon coincides, on the whole, with that of the rash itself; at any rate, it may remain quite visible for several days."

---

* A paper read to the Fever Hospital Medical Service Group of the Society of Medical Officers of Health, Nov. 23rd, 1923.

Schultz and Charlton found that this reaction could be obtained in the great majority of scarlet fever cases with a sufficiently well developed rash. For a series of 46 cases they report 40 positive reactions, five being doubtful and one negative; but they state, without giving particulars, that they have since obtained a higher percentage of negative results. They do not mention the source of the serum used in the tests, but merely say that they could detect no qualitative difference between the action of convalescent scarlet fever serum and that from normal persons. On the other hand, the serum from scarlet fever patients during the acute stage of the illness invariably gave negative results. They tested the serum of a number of scarlet fever cases taken at different stages of the disease and give the results shown in Table I. Apparently all the sera were from different individuals.

TABLE I.

Day of disease.	No. of cases tested.	Result.	Day of disease.	No. of cases tested.	Result.
1st	2	0	16th	1 1	0 +
2nd 3rd	1 3	0 0	17th	1 2	0 +
4th–13th	14	0	18th	1 2	0 +
14th	2 1	0 +	19th	2	+
15th	2 1	0 +	20th 21st	1 3	+ +

They conclude that the serum of the scarlet fever convalescent "recovers its lost power of blanching the rash between the fourteenth and nineteenth days of the disease." Thus Schultz and Charlton assume that their reaction is due to a normal property of human serum which is temporarily lost during the acute stage of scarlet fever, to be regained during convalescence. I shall show later that this is an unwarranted assumption. In the meantime, it may be noted that according to their own observations we should have to suppose that this mysterious property of normal serum disappears suddenly with the onset of scarlet fever. It is absent even on the first day of illness.

Implied Serological Means of Diagnosis.

Although Schultz and Charlton are in general very restrained and cautious in their attitude, and do not even suggest any practical application of their reaction in diagnosis, their unfortunate assumption as to its nature is, I think, partly responsible for a fallacy which has appeared in the work of their immediate followers. If their assumption were true, then obviously we should have a serological means of diagnosing cases of scarlet fever; a serum which does not give the reaction must be that of a patient in the acute stage of the disease.

This position has been adopted uncritically by Paschen,[2] Neumann,[3] and others. Although Paschen had the opportunity of testing the serum of a child five days before she developed scarlet fever, and found it negative, this did not shake his faith in the dogma. It was for him merely a puzzling exception to the rule. Paschen tested 71 scarlet fever rashes and found the reaction positive in 62; the source of the sera used is not mentioned. Neumann tested the sera of 23 scarlet fever convalescents and obtained positive reactions in all but three; he attributed the failure in these three cases to the fact that the rashes faded too soon. He noted that a serum which gave a positive reaction in one rash might fail to do so in another. Thus four sera tested on different rashes gave:—

Sera	+	0	Sera	+	0
2	3	1	1	1	1
1	2	1			

He tested the sera of 59 cases of scarlet fever within the first four days of the disease and found that of these only three gave the reaction. The sera of three children with rubella gave a negative reaction, and Neumann also regards these as being "remarkable exceptions" to the rule. In spite of these findings, Neumann formulates explicitly the rule for the diagnosis of doubtful cases of scarlet fever on this basis. If the serum gives a positive Schultz-Charlton reaction it is *not* from a scarlet fever case (presumably in the first fortnight of the disease); if the serum does not give the reaction it *is* from a case of scarlet fever.

Mulsow[4] tested the serum of acute cases of scarlet fever, convalescents and normal persons, giving the results separately. Omitting two cases where the reaction was doubtful, he found the sera from eight scarlet fever cases in the acute stage negative, the sera of six scarlet fever convalescents positive, and among the sera of seven normal persons one negative. His observations also show that a serum which gives a positive reaction with one rash may give a negative reaction with another. Mulsow rightly concludes that a negative reaction can give no help in the diagnosis of scarlet fever in the patient from whom the serum was obtained.

The observations of Tron[5] are much at variance with those of all others who have worked at the subject. It is possible that his standard of what constitutes a positive reaction is higher than usual. In 17 scarlet fever convalescents after the third week he obtained only 10 positive results; 15 cases of scarlet fever in the acute stage were negative; among 16 cases of follicular tonsillitis and laryngeal catarrh he found two positive, and among 12 cases of diphtheria four positive.

As regards the specificity of the test for the scarlet fever rash Table II. shows the number and nature of other rashes which have been tested by the intracutaneous injection of serum, all with negative results.

Inquiry into Nature of Schultz-Charlton Reaction.

About a year ago Dr. E. W. Goodall drew my attention to the Schultz-Charlton reaction, and with his help, and that of Drs. F. H. Thomson and C. E. Matthews, I have been making some inquiries into its nature. I am also particularly indebted to Dr. J. W. Mann, of the North-Eastern Fever Hospital, for his assistance in carrying out some of the tests.

There is no doubt that the reaction, when well marked, is a very striking phenomenon. As regards its appearance, there is little to add to the description given by its discoverers. One point of interest should, however, be noted. Where there is early and profuse desquamation the blanched area may remain visible for a week or more, being clearly marked off from the surrounding skin by the absence of desquamation. Schultz,[6] in a later paper, also notes this condition and emphasises the fact that the blanched area is an area of normal skin, as shown by the absence of exudative phenomena (sudamina and swollen papillæ) when these occur, as well as by the disappearance of the rash. In these well-marked reactions one cannot resist the impression that the injection of the serum has completely suppressed the whole sequence of pathological events which are occurring in the skin elsewhere. But these striking reactions are somewhat uncommon; the area of pallor does not always persist till the rest of the rash has disappeared; sometimes the rash reappears after an interval, and often it never completely disappears from the area affected. In the latter case it may be difficult to decide whether or not there has been any reaction. With regard to the time at which the reaction first appears, there is considerable variation. I have not seen it as early as the six hours mentioned by Schultz and Charlton, and it is certainly sometimes better marked after 24 hours than earlier.

A Toxin-Antitoxin Phenomenon.

From the beginning I have thought it likely that in the Schultz-Charlton reaction we have to deal with a toxin-antitoxin phenomenon; and the justification of the title chosen for this paper is that, after a study of the literature and consideration of our own results, I still think that this is the most probable explanation of the facts. I have shown elsewhere [7] that there is reason to believe that in scarlet fever there is concerned a toxin which presents certain points of resemblance to that of diphtheria. We have to suppose that the rash and other changes in the skin are due to a scarlatinal toxin which has entered into combination with the tissue cells; among the affected cells are those contractile elements which have been shown to exist even in capillary blood-vessels [8] and to the function of which the normal tone of the capillaries is due. The toxin interferes with the function of these cells and a loss of tone of the capillaries results in the erythema and exudative phenomena with which we are familiar in the scarlatinal rash. The serum injected, when it gives a positive reaction, we suppose to contain an antitoxin which is able to dislodge and neutralise the toxin fixed in the cells, and so to restore their normal function in the area affected. The period of delay, 12 to 24 hours, in the appearance of the reaction, is no doubt due to the fact that the toxin is attached to the cells, and some time is thus required for its neutralisation. When the rash fades in a normal manner the mechanism is probably different as this occurs long before any antitoxin can be demonstrated in the patient's blood.

Now diphtheria is a disease which in many other respects exhibits analogies and even relationships with scarlet fever. It is known that over 80 per cent. of so-called normal adults have appreciable amounts of diphtheria antitoxin in their blood, but we do not therefore assume that the diphtheria patient has antitoxin in his blood before he is attacked, and that he suddenly loses this antitoxin on the first day of the disease. It is, of course, known that the diphtheria patient has no antitoxin, or only inappreciable traces, in his blood before he is attacked by the disease, and the same is no doubt true of scarlet fever. The reason for the negative Schultz-Charlton reaction given by the serum of scarlet fever patients in the first fortnight of their illness is simply that the necessary antitoxin has not yet had time to develop. It follows that when the serum of a so-called normal person is found to give the reaction, this means, just as in the case of diphtheria, that the individual in question has acquired at least a certain degree of immunity to scarlet fever, either by an attack of the disease, or by an atypical illness which could not be diagnosed as such, or possibly by a series of sub-infective immunising doses, or by a combination of these events.

In diphtheria we have to deal with a known toxin and antitoxin which can both be accurately measured, and the Schick test gives an easy means of estimating, at least approximately, the amount of antitoxin in the blood of any individual. In scarlet fever, we are dependent, as yet, on casual occurrences in nature for our test toxin. This, fortunately, manifests itself in the scarlet fever rash in a form which is not altogether unsuitable for the demonstration of antitoxin, but which leaves much to be desired from a quantitative standpoint. We are dealing with two unknown variables, the amount of toxin to be neutralised, and the amount of antitoxin available for its neutralisation.

Differing Reactions of Same Serum in Individual Cases.

Let us now see how this hypothesis, founded on what is known in regard to an analogous disease, agrees with the facts. It was desired in the first place to ascertain how the same sample of serum reacts when tested on different scarlet fever rashes; 5 c.cm. of blood were taken from each of 14 scarlet fever convalescents in the fifth week or later. The sera after separation were pooled and distributed in ampoules in amounts of about 1 c.cm. This pooled serum was tested on 18 different rashes; 14 of these gave a positive, 1 gave a negative reaction, and in 3 no reading was possible owing to the whole rash having disappeared. The one case where no reaction was obtained was a very severe case with persistent rash which became brighter on the fourth day. The test was made on the fifth day of the rash. On the sixth day the patient was still delirious and the rash bright, but she made a good recovery without complications. In this case there was probably more toxin present than could be neutralised by the serum injected. Other observers have noted that in a case which subsequently proved fatal the rash was not blanched by the injection of serum (Wöhlisch and Mikulicz-Radecki [9]).

The serum from a normal adult, with a history of scarlet fever in childhood, was tested on eight cases; in seven it gave a positive reaction and in one a negative. The case which gave the negative reaction had a coarsely punctate rash with little or no diffuse erythema. This type of rash does not appear to be suitable for the test. With both these sera it was noted that the degree of the reaction varied much from case to case, although the same amount of serum was injected.

Twelve samples of serum from scarlet fever convalescents were now tested separately on a number of different scarlet fever rashes with the results shown in Table III.

Table III.

Sera.	+ Cases	0	Sera.	+ Cases	0
1	2	0	7	2	0
2	4	0	8	4	0
3	2	2	9	1	1
4	4	0	10	4	0
5	4	0	11	2	0
6	3	1	12	3	0

Again, it was noted that the reaction of a given serum varied considerably in degree according to the rash on which it was tested. It follows from these observations that in testing any serum a single distinct positive result is of value and can be accepted as indicating that the serum in question contains antitoxin whereas a serum can be shown to be negative only if it has been tested on a number of rashes, or better, if it has been tested on a case which has at the same time given a clear positive reaction with another serum. We can compare one serum with another, by testing both on the same rash, but owing to the variability of the test object we cannot, strictly speaking, do more than this in the direction of a quantitative estimation.

In order to find at what period of convalescence the reaction develops in the serum of the scarlet fever patient, some observations were made with the serum of the same patients taken at different times. As a rule, the sera taken on different days from the same case were tested on the same rash and could thus be compared quantitatively. The results are shown in Table IV.

Thus the time at which the reaction appears varies in different patients. It is not always found as early as the twenty-first day, and there is evidence of an increase in the degree of the reaction during the fourth week. The sera of three other cases in the first week gave negative reactions. Seven other scarlet fever convalescents were examined during the fifth week or later, and all their sera gave positive reactions. The sera of all the 25 convalescent cases examined were therefore positive.

TABLE IV.

Case.	Negative.	Positive.	Case.	Slight.	Well-marked.
1	3rd day	15th day	5	15th day	25th day
2	3rd ,,	18th ,,	6	20th ,,	29th ,,
3	7th ,,	17th ,,			
4	21st ,,	38th ,,			

Now, if our hypothesis be true, it should be possible to find individuals whose serum does not give the reaction, although they are not at the time suffering from scarlet fever either in the acute stage or in the early weeks of convalescence. At an early period I was able to satisfy myself that the serum of a healthy boy, aged 10, was quite without the property in question. This serum was tested on four rashes with negative results, two of which at the same time gave positive reactions with another serum.

A Question of Immunity.

Later, by a fortunate chance, I was able to test the serum of a girl, aged 5, a convalescent diphtheria case, who was attacked by scarlet fever four days after the sample of blood was taken. This serum gave a negative reaction. Another sample was taken on the thirty-eighth day from the onset of scarlet fever, and her serum now gave a positive reaction. This amounts to a demonstration that the property of the serum which gives rise to the Schultz-Charlton phenomenon is one which can be acquired as the result of an attack of scarlet fever; and this fact alone would appear to make it extremely probable that we are dealing with a question of immunity. It is, in fact, quite easy to find children of the ages at which scarlet fever is common whose sera give negative reactions. Not including the two negative cases already mentioned, I have found, among 13 children, seven whose sera were negative. One of these was in the acute stage of measles, one was a measles convalescent, and the remaining five were diphtheria convalescents. Of the six cases whose sera were positive, four were diphtheria convalescents, and two were cases of erythema, where the positive Schultz-Charlton reaction was of value in confirming the negative diagnosis as regards scarlet fever. In none of the children was there any history of scarlet fever.

In this connexion it appeared that it would be of interest to examine the blood of newly-born infants. Through the kindness of Miss Mocatto I was able to obtain from Queen Charlotte's Hospital four samples of blood from the umbilical cord, with corresponding samples of the maternal blood. These were tested in pairs on the same rashes with very interesting results. In each case the serum of the new-born child gave an exactly similar reaction to that of its mother. In two of the cases distinct positive reactions were observed. In one of these the mother gave a history of previous scarlet fever. The other two gave such feeble and indefinite reactions that it was doubtful whether they should not be classed as negative. The scarlatinal antitoxin, therefore, behaves like that of diphtheria, in passing through the placenta from mother to child, in such a way that the titre of the two sera is identical.

With regard to adults, it seems probable that the proportion of positively reacting sera is high; I have few personal observations, but if it were not so it would be difficult to understand the attitude of previous writers on the subject, who have not thought it worth while to distinguish between the serum of "normal persons" and that of scarlet fever convalescents in giving their results. Omitting the maternity cases already referred to, I have examined the sera from nine adults with eight positive results and one negative.

In three of the positive cases there was a history of scarlet fever many years before; five of the cases were nurses in scarlet fever wards with no history of scarlet fever; one of these gave a negative reaction; the other four gave very well-marked positive reactions. The occurrence of these marked reactions in nurses exposed to frequent and close contact with scarlet fever patients certainly suggests the possibility of immunisation without a definite attack of the disease. The remaining case was one of enteric with a rash which was probably the result of enemata; here again the positive reaction was of assistance in excluding the diagnosis of scarlet fever.

Technique of the Reaction.

A few points in the technique of the reaction may now be noted. A positively reacting serum may be heated for half an hour at 55° C. without impairing its power. It may also be stored for long periods in the cold room without alteration. I have obtained positive reactions with sera kept thus for nine months. As regards the quantity of serum to be injected, this should be at least half a cubic centimetre, although some sera give the reaction in smaller amounts. In the observations described above the amount of serum used was from 0·7 c.cm. to 1 c.cm. This seems a large amount to be injected intracutaneously, but experience has shown that after the prick of the needle and the injection of the first few tenths of a cubic centimetre, the remainder of the injection causes the patient no discomfort.

It is hardly to be expected that a complete demonstration of the nature of the interesting phenomenon to which I have called your attention can be obtained until we know something more of the cause of scarlet fever. In the meantime, the evidence in favour of the toxin-antitoxin hypothesis is, I think, sufficient to justify us in undertaking a more extensive investigation of the phenomenon from this point of view. Such an investigation would, no doubt, throw light on the epidemiology of scarlet fever, just as the Schick test has done in the case of diphtheria. In another way, also I think, the reaction is likely to help in the elucidation of the ætiology of scarlet fever. Claims are put forward from time to time that a particular organism, isolated from the throat or elsewhere, is the cause of scarlet fever. The fact that no experimental animal can be found which is susceptible to scarlet fever, in the sense of showing all the symptoms of the human disease, has proved a barrier to the proof or disproof of these claims. If, however, our hypothesis is correct, it seems highly probable that the true causal micro-organism will be capable of producing a toxin, and, by the immunisation of animals, an antitoxin, of which the latter should give the Schultz-Charlton reaction in man.

It would be well to maintain an attitude of reserve towards the claims put forward for any particular micro-organism until it has been shown to be capable of producing such an antitoxin.

ON IMMUNO-TRANSFUSION.

By LEONARD COLEBROOK, M.B., B.S. Lond.,
ASSISTANT, BACTERIOLOGICAL DEPARTMENT, MEDICAL RESEARCH COUNCIL;
AND
E. J. STORER, M.R.C.S.,
ASSISTANT, INOCULATION DEPARTMENT, ST. MARY'S HOSPITAL, LONDON.

(From the Inoculation Department, St. Mary's Hospital.)

(Concluded from p. 1334.)

Procedure Employed for Drawing Blood from the Donor and Defibrinating It.

Apparatus Required.—This is shown in Fig. 1.‡ A needle, about two feet of rubber tubing, and a short piece of glass tubing, serve to conduct the blood from the donor's vein to the bottle. The latter is of about one litre capacity, and is fitted with a rubber bung. Through the centre of the bung is passed a glass rod, bent at its lower end in the form of a U, which is intended to collect the fibrin clot during defibrination of the blood. The escape of air from the bottle as the blood runs into it is provided for by a third hole through the bung. This is lightly plugged with cotton-wool (A). Attention may be called to three points of detail: (1) The bore of the needle should be not less than 1½ mm.—with this size it is usual to draw off 500 c.cm. of blood in four to six minutes. A smaller needle might become partially blocked with clot before the bleeding was completed. (2) The glass tube admitting the blood to the bottle should not extend more than an inch or two below the bung. In this position we can easily observe the rate of flow from its orifice. (3) When the bottle and its connexions are kept sterilised for use in an emergency, the needle should be detached and sterilised independently—otherwise it will rust.

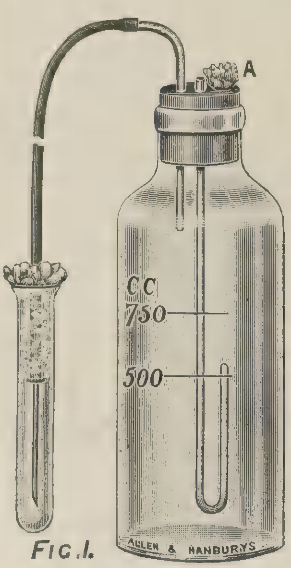

FIG. I.

Apparatus employed for drawing blood from the donor and defibrinating it.

Technique of the Bleeding Operation.—Our practice has followed closely the description given by Fleming and Porteous (The Lancet, 1919, i., 973) to which the reader is referred. It has never been found necessary to incise the skin and expose the vein of a donor. Two points only seem to us to require emphasis—viz., the importance of obtaining at the outet the proper degree of venous congestion by the tourniquet, and of maintaining this, so long as the blood is flowing, by the donor's muscular efforts. He should be instructed to close the fist tightly and relax again five or six times a minute. This simple but effective trick is often forgotten.

Defibrination of the Blood.

Our aim is to obtain the blood in a permanently fluid form with nearly its normal content of corpuscles—in particular, of white corpuscles. In other words, we must so arrange things that the great bulk of the corpuscles are not caught up in the fibrin meshwork at the moment of clotting. To secure this result we keep the blood continuously in motion around a rigid scaffolding on which the fibrin filaments as they form become very rapidly entangled. The scaffolding is provided in our apparatus by the glass U. Our procedure is as follows: Commencing not later than one and a half minutes after the blood first begins to flow into the bottle, we move the latter without ceasing in a rotatory fashion and fairly briskly until at least six minutes after the needle is withdrawn from the vein. As stated above the time usually taken to collect 500 c.cm. of blood is 4 to 6 minutes. Shaking of the bottle has, therefore, to be kept up for 10 to 12 minutes. The fibrin clot in blood treated in this way is found tightly adherent to the glass U. Its volume is about 10 to 20 c.cm. for 500 c.cm. of blood. The fluid blood retains practically all its red corpuscles, and 70 to 75 per cent. of its leucocytes.

On the Question of Keeping the Donor's Blood for Some Hours Before Injection.

This question is of some practical importance. The results already obtained allow one to hope that immuno-transfusion will prove of value in the treatment of fulminating septicæmic conditions such as acute puerperal fever, osteomyelitis, &c. If this expectation is justified it is important that the method should be made available at short notice for patients in the country as well as in the cities. This will be possible if it can be shown that the quality of the blood does not undergo appreciable deterioration within three or four hours of its being withdrawn from the donor. At a summons by telegram or telephone a donor could be chosen from a register kept in cities and large towns, immunisation and bleeding could be carried out by someone familiar with these procedures, and the blood could be transported without delay to the patient's bedside perhaps many miles away.

The following experiments bear upon this matter. They were undertaken to show whether the bactericidal efficiency of the blood—for it is with this property that we are chiefly concerned in carrying out an immuno-transfusion—becomes diminished on keeping it, and also whether such diminution is dependent upon the temperature at which the blood is kept. A normal individual was inoculated subcutaneously with staphylococcus vaccine. Specimens of blood were taken before the inoculation and four hours after, and each was defibrinated. The specimen taken four hours after inoculation was divided into two parts, one being incubated at 37° C., the other kept at room temperature. Tests of the hæmo-bactericidal efficiency were carried out (by the method of "slide cells," as in experiments 1 to 7) with the bloods taken before and after inoculation, and also with the latter sample after it had been kept for stated periods at the different temperatures. The results were as shown in Table IV.

TABLE IV.

Blood of—	Number of colonies which grew in :—	No. of Staph. implanted in the blood (as determined by an agar count) : *(882)	(294)	98
L. C., inoc. with 500 mill. Staph.	Blood taken before inoculation	47	18	5
	Blood taken 4 hr. after inoculation and tested immediately	11	9	2
	Same blood tested after standing :			
	1 hr. at room temperature ..	27	11	5
	1 hr. at 37° C.	40	10	5
	4 hr. at room temperature ..	34	13	4
	4 hr. at 37° C.	29	12	7
E. J. S., inoc. with 750 mill. Staph.	Blood taken before inoculation ..	92	27	11
	Blood taken 4 hr. after inoculation and tested immediately	25	5	4
	Same blood tested after standing :			
	1 hr. at room temperature ..	20	5	1
	1 hr. at 37° C.	14	2	2
	4 hr. at room temperature ..	49	16	4
	4 hr. at 37° C.	26	13	2

* The figures given in brackets represent calculated, not actual, counts.

As these two results did not give very clear indications a third experiment was carried out by Dr. H. B.

---

‡ Messrs. Allen and Hanburys are prepared to supply the complete apparatus.

Maitland. The plan of this experiment differed slightly from the foregoing in that, at each testing, the blood was implanted in bulk with living Staphylococci, and *several* 50 c.mm. samples were transferred to slide cells for incubation. Experimental errors were in this way minimised. The result obtained was as shown in Table V.:—

TABLE V.—*Blood of E. J. S., Inoculated with 1000 Million Staphylococci.*

—	No. of Staph. implanted in blood (as determined by agar counts).	No. of colonies which grew in the blood.	Percentage of Staph. which survived in blood.
Blood taken before inoc. . .	198	28, 44, 37, 44 } aver. 44, 53, 46, 60 } 44	22
Blood taken 4 hr. after inoc. and tested immediately	177	19, 12, 6, 3, } aver. 7, 9, 5, 10 } 9	5
Same blood tested after-standing: 1 hr. at room temp.	155	3, 6, 10, 10, } aver. 7, 5, 16, 16 } 9	6
1 hr. at 37° C. . .	142	6, 8, 6, 12, } aver. 15, 8, 13, 7 } 9	6·6
4 hr. at room temp.	745*	17, 13, 12, 16, } aver. 30, 36, 42, 27 } 24	3·2
4 hr. at 37° C. . .	686*	36, 49, 44, 29, } aver. 38, 36, 34, 29 } 37	5·4

* A different staphylococcal emulsion was here employed.

The results set out in the last column of the table show—and this experiment carries more weight than the other two by reason of the multiple sampling adopted at each test—that an "immune" blood loses little, if any, of its bactericidal efficiency on being kept for periods up to four hours, either at room temperature or at 37° C.

We conclude, then, that it is permissible, if circumstances require it, to allow a period of several hours to elapse between the bleeding of the donor and the transfusion of the patient, and that it is not necessary to keep the blood warm during the interval.

With regard to this last point it will, perhaps, be urged that, quite apart from any question of deterioration of the quality of the blood, it is manifestly desirable that this should be warm when it is injected into the patient. We would suggest that this consideration is probably of very little importance. The stream of blood which we inject into the patient is so small in relation to the very large volume of venous blood with which it is almost immediately mixed in the great veins and the auricles, that it can have only an extremely small effect in reducing the temperature of the whole circulating blood.

Procedure for Injecting the Blood into the Patient.

To drive the blood out of the bottle into the patient's vein a positive pressure is required. This may be obtained (*a*) by gravity, using the "funnel-and-tube method" for the injection; (*b*) by means of an air pump of the Higginson type, as recommended by Robertson,[8] Fleming and Porteous,[9] and others; (*c*) by means of a syringe acting as a combined suction and force pump, as recommended in 1911 by Fleming and Colebrook[10] for the injection of "606."

We have never employed the first method. It serves well enough, no doubt, if one exposes the patient's vein and ties in a cannula, but it may lead to difficulties when one dispenses with that unnecessary procedure and simply injects the blood through a needle. The patient's veins, when immuno-transfusion is required, are often partially collapsed, and one cannot always be sure of plunging the needle directly into the lumen, or of keeping it in that position throughout the operation. In these circumstances it is of the utmost importance that the pressure system should enable us at the commencement of the operation, or at any moment subsequently, to satisfy ourselves that the point of the needle is rightly placed. We need assurance also that its lumen has not become blocked during the progress of the injection. These requirements are met: (*a*) If the injecting apparatus allows us to suck blood back through the needle at will; and (*b*) if we are continually informed that the blood is flowing satisfactorily from the apparatus into the vein. For both purposes the funnel-and-tube system is ill-adapted.

The same criticism applies to the air-pump method which we used for several months. If all goes well it works admirably, but if we fail at first to lodge our needle in the lumen of the vein—or if, subsequently, some obstruction develops owing to the formation of clot in the needle, this pressure system is found to be lacking in adaptability and control. We come then to the third method, which has proved, in our hands, the most satisfactory. The proposal to adopt it for the purpose of transfusion came from our colleague Dr. Alexander Fleming. Although at first sight it may appear a little complicated, a few minutes' practice with it will suffice to put the operator at his ease.

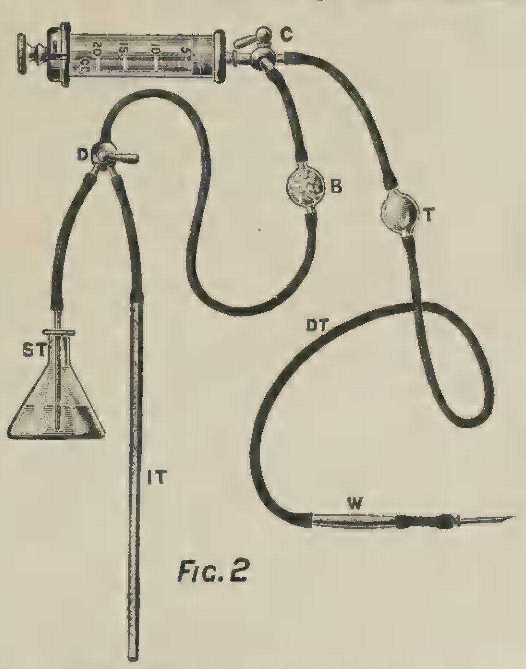

FIG. 2

Apparatus employed for transferring the defibrinated blood from the bottle to the patient's vein.

Apparatus Required.—This is shown in Fig. 2. The essential features consist of a record syringe connected by means of a two-way tap (C) with (I.T.) a thick-walled rubber tube and glass connexion through which the blood is sucked up out of the bottle into the syringe (the "intake tube"); and (D.T.) a second thick-walled rubber tube fitted with a needle—the delivery tube—through which the blood is driven from the syringe into the patient's vein. To these essential features are added one or two simple contrivances which make for convenience and safety in carrying out the injection. They are as follows: (1) On the intake tube is incorporated a glass bulb (B) loosely fitted with glass-wool (*not cotton-wool*, which would soon obstruct the flow of blood). This is intended to catch any small fragment of clot which might be free in the blood. Probably it is unnecessary. We have never seen such loose fragments of clot. (2) On the delivery tube is incorporated another glass bulb (T) which serves as an air trap. If a few bubbles of air should be unwittingly driven over from the syringe with the blood they will lodge in the convexity of this trap while the blood passes along to the needle. (3) At (D) a second two-way tap is introduced, giving connexion by rubber and glass tubing (ST) to a bottle of sterile physiological salt solution. This provision enables the operator, at the commencement of the injection or at any time subsequently, to fill the delivery tube with salt solution in place of blood. (4) A short piece of glass tubing (W) inserted near the end of the delivery tube serves as a window, the purpose of which will appear when we describe the technique of the injection. (5) Connecting the needle with the end of the delivery tube is a metal " adapter."

Attention may be called to some points of detail in connexion with this apparatus: (*a*) If the syringe is sterilised by sucking hot oil (120° C.) into it it will work much more smoothly than it will after being boiled. (*b*) The needle should be considerably smaller than that employed for taking blood from the donor. A bore of about one millimetre will be suitable. At the risk of pointing out the obvious, we would urge that the operator should not take for granted that its point is sufficiently sharp. If he wishes to avoid trouble he will himself examine it with a hand lens, and, if necessary, touch it up on a fine sharpening stone. (*c*) It is well to ascertain, before commencing the injection, that the nozzle of the syringe makes a tight joint with its two-way tap. (*d*) The joints between rubber tubing and glass, and also those connecting the tubing with the two-way taps, should be secured with a turn of thin wire or a ligature—otherwise, after being sterilised several times, they may leak.

Technique of the Injection.—The sterilised apparatus is first assembled at the bedside, the syringe being connected with its two-way tap (C), the glass tube I.T. being put into the blood through the hole in the bung which until now has been closed with a cotton-wool plug (A), and the other tube (S.T.) placed in the flask of salt solution. The next step is to fill the whole system of tubes—and also the syringe half full—with salt solution. (In order to expel the air from the delivery tube the needle end must, of course, be held up at arm's length while salt solution is driven into it from the syringe.) This done, we are ready to commence the injection. While an assistant compresses the upper arm with his hand (this arrangement is preferable to the use of a tourniquet, as the pressure can be released more promptly and with less risk of dislodging the needle) the operator inserts the needle into the vein at the elbow. As soon as he thinks its point is well in the lumen of the vein a second assistant, in charge of the syringe, pulls lightly on the piston until blood appears at the glass window (W). With this assurance that his needle-point is correctly placed, the operator, still holding on to the needle himself, gives the word for the compression of the upper arm to be released and the injection to begin. A few cubic centimetres of salt solution are first injected in order to give renewed assurance that the needle is still in the vein. The assistant in charge of the syringe then turns the tap C from the delivery tube to the intake tube, and the tap D from the tube S.T. to the tube I.T. and proceeds to fill the syringe with blood. This done he turns the tap C back towards the delivery tube and injects the blood into the vein. By alternate filling and emptying of the syringe in this manner the transfusion is completed. One difficulty only is likely to arise after the needle is satisfactorily lodged in the vein. If, for any reason, there is delay in commencing the injection—or if this is interrupted—a little blood may flow back from the vein into the needle and delivery tube, and, clotting there, prevent or impede the further progress of the injection. The operator has only to be aware of this possibility to avoid its occurrence.

In conclusion we would emphasise the desirability of injecting the blood slowly. On one occasion when we were using the Higginson pump apparatus, most distressing symptoms were caused by inadvertently hurrying the injection of the first 100 c.cm. of blood. It is our practice now to take at least 20 minutes over the injection of 500 c.cm. of blood—the quantity we usually employ.

Results of Treatment by Immuno-transfusion.

It is always a difficult matter to convey in print what is thought to have been achieved by any method of treatment. Either the reader must be given all the evidence on which to form his own judgment—a wearisome and unsatisfactory procedure for both writer and reader—or, failing that, the writer must state broadly his estimate of the value of the method, and, for the reader's guidance in accepting or rejecting that estimate, must indicate the nature of the evidence on which it is based. We shall here employ the latter alternative, and, before referring to the results we have obtained, shall deal beiefly with the problem of evidential methods in its bearing upon these results. Sir Almroth Wright has devoted much thought to this problem and we may quote from him as follows:—

" The statistician has done his very best to persuade the world that there is only one way—that being the statistical method—by which the efficacy of a therapeutic method can be scientifically put to the test. The statistician asserts that there should in connexion with every therapeutic method be set out the results of a long series of cases treated, and that there should be compared with these results those of a similar series of untreated control cases. This method, except in connexion with very common and comparatively light infections (where no one is going to go to the trouble of applying it) is not only impracticable but almost inevitably fallacious. It is impracticable (*a*) because of the difficulty of assembling, unless we include all grades of infection and patients affected with all sorts of complications and accessory infections, sufficient cases for statistical operations; and (*b*) because of the all but impossibility of providing, by withholding treatment from a very large number of patients, the theoretically necessary number of control cases. And statistical treatment is almost inevitably fallacious because when we take an assortment of patients suffering from all different grades of infection, different complications and accessory infections (to say nothing of a percentage of patients wrongly diagnosed), and now proceed to divide these by any system into two groups, we shall almost inevitably have two groups which would not, if they had both been left to themselves, have furnished the same results. We may in view of this be devoutly thankful that there are non-statistical methods by which the efficacy of therapeutic measures can be tested.

" (1) Clinical evidence of the efficacy of a therapeutic measure is furnished by a cure effected in an intractable and progressive local infection, and by rescue from death in a plainly desperate case. But the evidence must not be limited to the citation of only one or two of such cases, for provision requires to be made for an occasional profound blunder in prognosis, and for the possibility of some undiscerned factor other than the treatment applied having been responsible for the transformation in the patient's condition. The difficulty of furnishing convincing testimony of dramatic improvements, and cures produced in hopeless cases will consist in the difficulty in finding words (for photographic records will only rarely be available)—words graphic enough to depict to the reader the desperate conditon of the patient when treatment was initiated and the resurrectional change that followed. Where verbal description is inadequate and photographic records are not available, the reader will have to be largely guided by his estimate of the trustworthiness and sobriety of judgment of the reporter.

" (2) To the clinical evidence furnished by cures of intractable and progressive local infections or rescues from death supervening in desperate conditions there can be superadded immunological data procured by measuring the antibacterial power of the patient's blood before and after treatment, and by measuring, in addition, when immuno-transfusion or serum-therapy is in question, the antibacterial power of the blood or serum injected. When such data testify to an improvement in antibacterial power following directly on treatment, and when they further show in connexion with immuno-transfusion or serum-therapy that the blood or serum incorporated was calculated to produce such a result, a previously existing strong presumption that the benefit witnessed resulted from the treatment will (for the man who consents to regard immunological data) be converted into a practical certainty.

" (3) Additional but not conclusive clinical evidence of the efficacy of a therapeutic measure is furnished by rapid and striking recoveries supervening upon treatment in serious but not desperate local and general infections, and by unambigious temporary improvements in cases which afterwards terminate fatally.

" (4) The evidential force of such clinical data is increased when these are supplemented by immunological data which show that treatment was regularly followed, and improvement preceded, by a marked increase in the antibacterial powers of the blood.

"The rôle of immunological data in the appraisement of value of therapeutic measures will have become clear. In the case where a cure has been obtained immunological data can, as we have seen, convert the presumption that the cure is due to treatment into a certainty. They can also render invaluable logical service by silencing the witticisms which make merry over the idea that it can, under some circumstances, with propriety be claimed in connexion with a patient who has succumbed that the therapeutic measures applied effectually did their office. Immunological data not only put a quietus upon such witticisms, but moreover they bring home the fact that no achievement of increased antibacterial powers is of any permanent avail when we are dealing either with a disseminated infection which is disproportionately large in comparison with the antibacterial forces we can bring against it, or with an unevacuated nidus of infection which goes on poisoning the blood."

With these considerations before us we may now briefly summarise the evidence afforded by our records that immuno-transfusion has been of value. The cases referred to have either been treated by us or have come closely under our cognisance.

(1) Of "plainly desperate cases" in which rapid improvement or definite cure has been obtained we have three records. One case was that described by Sir Almroth Wright in 1919, of severe streptococcal infection of the sacrum and ilium, to which reference has already been made. Another was the case of mastoid suppuration and lateral sinus thrombosis (streptococcal infection) referred to in the recent paper by Wright, Colebrook, and Storer (THE LANCET, 1923, i., under Example 3, p. 476). In this case immunological data (determinations of the strepto-phagocytic power) enabled us to correlate the patient's quite astonishing recovery with an increase of protective substances in the blood.

The third case, under the care of our colleague, Dr. John Freeman, was that of a lady, aged 74, who, following upon a mosquito bite, developed a very severe streptococcal cellulitis of the forearm, which soon extended to the upper arm and axilla. In spite of very free multiple incisions, the cellulitis was not checked and the erysipelas which accompanied it began to invade the trunk. The surgeon who was called in decided that amputation must be done in order to save life, but when he arrived to perform it the patient's condition was so grave that he judged her chance of surviving the operation was too slight to justify it. The case was therefore regarded as quite hopeless when Dr. Freeman was asked to see her. A culture he made from the arm yielded a pure and copious growth of streptococcus, and on testing her blood he found that the smallest addition of vaccine only served to reduce its already feeble phagocytic power. He therefore decided upon immuno-transfusion. The day following this treatment the patient's condition was already better and from that time she made good progress, the erysipelas subsiding, and no further operative treatment being required. After ten days a swab from the wounds on the arm yielded no culture of streptococci.

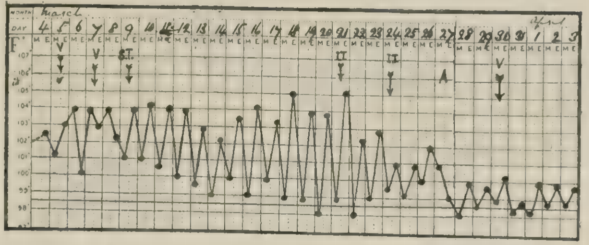
In addition to these three desperate cases which recovered we may refer very briefly here to a case of malignant endocarditis in which only temporary but nevertheless striking improvement was obtained. The patient was a man, aged 56, who had been ill with irregular fever for 12 weeks before treatment was begun. Streptococci were grown from the blood in considerable numbers on several occasions. After three immuno-transfusions at intervals of two to three weeks, and a few intravenous doses of vaccine, his temperature came to normal and kept down for several weeks, his general condition showing a corresponding improvement. The bloodstream was, however, never freed from Streptococci, and the patient finally died from circulatory collapse.

Turning now to the cases we have treated which may be grouped under the heading "serious, but not desperate infections" (Classes 3 and 4 above) we find in our records nine cases in which evidence of the value of immuno-transfusion was furnished by rapid and striking improvement, and, in some of them, also by immunological data. The salient features in respect of each of these cases were as follows:—

CASE 1.—A very grave case of staphylococcal osteomyelitis under the care of Mr. Maynard Smith. Both femora, one fibula, and the phalanges of one finger were affected and the boy had already developed pneumonia. Twenty-four hours before the transfusion his life was almost despaired of, but he rallied slightly, and following the injection of blood there was—to quote Mr. Maynard Smith's words—"a great and immediate improvement." From that time the boy held his own, but recovery was necessarily slow. There was a slight recrudescence of infection three months later. (The immuno-transfusion in this case was carried out by our colleague Dr. Porteous.)

CASE 2.—A child suffering from a generalised streptococcal infection with abscesses in the elbow-, ankle-, and wrist-joints. It will be seen from the accompanying temperature chart (Fig. 3) that two intravenous doses of vaccine and also a simple transfusion—i.e., of unimmunised blood—had failed to influence the infection and that a very satisfactory improvement followed the two injections of immunised blood, even in spite of the fact that an abscess remained unopened in the elbow-joint. When this focus was dealt with the boy's condition improved still further and he completely recovered. Some immunological data relating to this case will be found in the paper by Wright, Colebrook, and Storer, p. 476.

FIG. 3.



V, inoculation of vaccine. S.T., simple transfusion, 20 c.cm. I.T., immuno-transfusion, 25 c.cm. A, abscess of elbow-joint opened.

CASE 3.—A case of osteomyelitis of the frontal bone. Striking improvement followed the transfusion and the patient continued to do well for some time. Eventually an abscess developed and the patient did not long survive the operation undertaken to deal with this. The increased hæmo-bactericidal power of the patient's blood 24 hours after the transfusion and also that of the donor after immunisation are shown on p. 476 of the paper just referred to (*supra*).

CASE 4.—A case of puerperal infection. (Blood culture negative.) The temperature fell after the first transfusion, but rose again some days later. Complete recovery after a second immuno-transfusion.

CASE 5.—Female. Very severe streptococcal cellulitis of hand and arm, progressing in spite of multiple deep incisions. Condition considered critical. Remarkable improvement immediately during the 24 hours following immuno-transfusion and uninterrupted recovery.

CASE 6.—A boy suffering from septic infection of stump (streptococcus infection) following amputation through upper third of humerus for trauma. His condition caused anxiety, but began to improve at once after immuno-transfusion. Complete recovery.

CASE 7.—Male, with portal pyæmia following appendicitis and cholecystitis. Made good progress for several days after immuno-transfusion. He was extremely ill at the time of the transfusion, but held his ground and certainly improved somewhat during the following four days. Unfortunately, on the fifth day the sutures of his abdominal wound cut out and he did not long survive the operation required to deal with this.

CASE 8.—Male, with acute streptococcal epidemic infection (which resulted in three deaths). Patient had high fever but no localising signs. Blood culture negative. His condition was much improved on the day following immuno-transfusion and the temperature came to normal within 36 hours.

CASE 9.—Female. Severe puerperal infection. Pelvic cellulitis. Clinical improvement followed immuno-transfusion and was correlated with improved hæmo-bactericidal power (see below). Condition subsequently grew worse;

patient refused further treatment. Post-mortem revealed thrombus in inferior vena cava. The following experiment shows increased hæmo-bactericidal power to Staphylococcus of patient's blood 24 hours after immuno-transfusion. (Slide cell method.)

TABLE VI.

—	—	—	26	3	88
—	—	—	13	0	100

In addition to those specified above we have records of seven cases which did not furnish any evidence that immuno-transfusion was of value. These were as follows :—

(*a*) A case of malignant endocarditis in a child associated with an unusually heavy infection. (Blood cultures when the patient first came under treatment yielded 76 colonies of streptococci per cubic centimetre of blood, and later on the number increased to 200.)

(*b*) A patient with colitis of many months' standing, who was absolutely in extremis when the transfusion was carried out, being too weak to speak, and incontinent.

(*c*) A case of puerperal pyæmia with very large abscesses which could not be adequately drained.

(*d*) A case of streptococcus septicæmia occurring in a very debilitated subject already suffering from generalised eczema and cellulitis.

(*e*) A case of puerperal septicæmia in the country whose general condition was extremely bad as the result of continued high fever for seven weeks and many rigors.

(*f*) A case of very advanced phthisis with laryngitis.

(*g*) A case of chronic mucous colitis of the neurasthenic type. There was no sufficient indication in this case for immuno-transfusion, which was carried out rather as a policy of despair—the patient having failed to respond clinically to vaccine-therapy and other forms of treatment.

In conclusion, we may remark that the results so far obtained represent only a beginning. It is quite possible, indeed probable, that with increasing knowledge we shall be able in the future to effect a still greater immunisation of the donor's blood and achieve with it correspondingly better therapeutic results.

Grateful acknowledgments are made to Sir Almroth Wright for his continual help and criticism; to Dr. H. B. Maitland, who worked with us for some months and to whom we are indebted for the records of several experiments; to Mr. Alexander Fleming for suggestions in connexion with technique; and to Dr. Freeman and Dr. Porteous for particulars of cases treated by them.

Glasgow Northern Medical Club held their annual At Home on Dec. 11th in the Grand Hotel. The gathering was large and representative, and a very enjoyable evening was spent.

THE TREATMENT OF LIVER ABSCESS BY ASPIRATION.

BY A. R. NELIGAN, M.D. LOND.,
PHYSICIAN TO THE BRITISH LEGATION AND MEDICAL OFFICER TO THE PERSIAN GOVERNMENT HOSPITAL, TEHERAN.

I HAVE read recently in THE LANCET[1] the paper by Manson-Bahr, Low, Pratt, and Gregg on the treatment of liver abscess by aspiration. The writers are to be congratulated on their excellent results in the 15 cases described, and on the way in which they have set them out. My experience is not as great as theirs, but as I am a firm believer in the aspiration treatment I may be allowed to express my agreement with their methods. Indeed, almost the only criticism, if criticism it be, that I have to make on this excellent paper is one of surprise that its authors should have felt obliged to insist so strongly on its advantages as compared with open operation. Is not the aspiration treatment firmly established in tropical practice? And has it not been so, not "recently," but ever since the publication of Rogers's work—that is to say, for the last 10 years? Personally on reading his book, "Dysenteries," in 1913, I adopted the method and quickly became convinced of its value. As I write, however, I am reminded of two facts which suggested to me at the time that the aspiration treatment had not come into its own; one was Lieut.-Col. E. O. Thurston's analysis[2] of a series of cases of liver abscess treated in Bengal hospitals by open operation with 40 per cent. mortality; the other was that when last on leave I was asked to read a paper on the method. I desire, therefore, most emphatically to subscribe to all the statements made by Manson-Bahr and others. There is no doubt that, both for patient and surgeon, the aspiration treatment is preferable in every way for the very great majority of liver abscesses to open operation. I feel, indeed, that, with the exception to be described below, to open one is as much to be avoided as to open a tuberculous abscess. On the one side there is, or may be, a difficult operation under general anæsthesia, with a definite operative risk, a long period of convalescence, with daily expensive dressings and complicated endeavours to maintain asepsis and too often secondary infection, and, in the case of debilitated patients, death. On the other side there is a puncture (with or without local anæsthesia) and a collodion dressing, which may have to be repeated once, or in some cases twice or thrice. In the intervals the patient lies in bed undisturbed and free from pain, receiving his emetine injections, and causing neither anxiety nor trouble. The exception mentioned above is the abscess in the epigastric or hypochondriac regions, which presents no definite evidence of having formed adhesions with the parietes. Here it is safer to incise the abdominal wall, pack off the peritoneal cavity, and drain.

Technique.

As regards operative technique I have little to add to what is recommended in the paper quoted.

Site of Operation.—Under "swelling" is no doubt included pitting of the skin on pressure, a most important and helpful sign when present. In the absence of localising signs, and after unsuccessful punctures at other sites, one should always be made near the angle of the right scapula. This, I think, is mentioned in Manson's book. I remember assisting at an operation when several unsuccessful punctures were made in the lateral and anterior surfaces of the liver; the abdomen was then opened, and still no abscess was found. Finally a puncture was made near the angle of the right scapula and pus withdrawn at once.

I have rarely used general anæsthesia. A small skin incision or stab wound with a tenotomy knife makes the introduction of the large trocar of an aspirator easy. There is no pain once the body wall has been traversed. The statement that it is not necessary to inject a solution of quinine or of emetine into the abscess cavity after the pus has been aspirated, as recommended by Rogers, is interesting. I have notes of a small acute abscess which recovered without their use after withdrawing only a drachm of pus with an exploring syringe. In future I shall treat some of these cases without injections into the cavity, but I do not think I shall omit them in the case of patients who are very weak or who have not received some emetine before aspiration. I have seen two cases in which there was a secondary infection, one with a streptococcus, the other with a bacillus and a diplococcus, and in which therefore I did not expect a very favourable result. Did the injection of a solution of quinine into the abscess cavity help towards their recovery? "The effusion of serum into the abscess cavity probably takes place normally, and should be regarded as the natural method of repair." My experience corresponds with the first half of this sentence, but the effusion has on several occasions been accompanied by a rise in temperature, and this fell after a second aspiration. The serum was stained with altered blood and contained no formed elements. I, too, have never seen symptoms which could be set down to internal hæmorrhage, after exploring the liver with either needles or trocars.

---

Diagnosis.

The frequent absence of a leucocytosis in abscess of the liver is well emphasised in the paper. It is a most important factor for those who are beginning tropical practice to learn. Lesions of the pleura at the right base, be they a recent small serous effusion or a chronic empyema, may cause difficulty in a country where abscess of the liver occurs. Tenderness on pressure between the ribs occurs in both conditions (a fact which, by the way, I have not seen mentioned in text-books), and it is a classical sign in hepatitis. On the other hand, an abscess in the upper posterior part of the right lobe of the liver may cause displacement of the heart's apex beat, to say nothing of dullness and weak breath sounds. Indeed, in the case of empyema, there may be doubt even after finding pus with the needle, for liver pus is not always of the anchovy colour. In yet other cases there may be a lesion of the pleura together with an abscess of the liver. The patient is frequently a villager from some distant part, and the history often of no assistance. Returning to that important physical sign, tenderness on pressure between the ribs (present in the majority of cases of hepatitis, and often the sole indication as to where to explore), it may in some cases seem to fail us. It is not easy for a patient of low intelligence to distinguish between a superficial pain caused by squeezing the integuments between finger and rib and the deep tenderness due to pressure on an inflamed organ. Indeed, people who are very ill and thin may complain of pain at whatever point of the body pressure is made. In these circumstances I find it useful to explain as clearly as possible that I am searching for deep tenderness, and then to compare the two sides of the chest, examining methodically the intercostal spaces with the same degree of finger pressure. In this way the patient learns what is the sensation due simply to pressure on skin and rib, and whether, on one side or the other, there is an added discomfort, which he may now be able to say is definitely deeper than the surface.

Altogether the region of the diaphragm presents some of the most interesting problems in clinical diagnosis, especially when a patient comes during one of the apyrexial intervals which may occur during the course of a hepatic abscess. The X ray screen must be a great help in the diagnosis of the various conditions found here, but I have not had the advantage of being able to use it.

In concluding I would like to describe shortly three cases which bear further striking testimony to the value of aspiration and which show that it is sometimes necessary to remove collections of serum.

CASE 1.—Cultivator. Seen August 23rd, 1918. Abscess ight lobe of liver; no leucocytosis; 75 ounces of pus spirated same day (emetine gr. 2). On the 31st temperature ose to 100° F.; 16 ounces of serum aspirated (quinine gr. 10). emperature fell to normal, and patient insisted on leaving ospital on Sept. 4th as he "felt so well."

CASE 2.—Labourer. Seen May 9th, 1919. Abscess left lobe of liver and of spleen; leucocytes 8000; 62 ounces of pus aspirated on the 13th; trocar entered in middle line of abdomen 2 inches below xiphisternum (emetine gr. 2). Pus again aspirated from the left lobe on the 25th 14 ounces (quinine gr. 10), on June 25th 6 ounces (emetine gr. 2), and July 4th 6 ounces (quinine gr. 5). The patient has been seen recently and has been well in the interval.

CASE 3.—Hod-carrier. Seen May 27th, 1919. Abscess right lobe of liver; leucocytes 5600; 37 ounces of pus aspirated same day (emetine gr. 2). On June 16th, 27 ounces aspirated (emetine gr. 2). On the 20th (emetine gr. 1) and 26th, and on July 12th (quinine gr. 10), temperature rose and blood-stained serum was aspirated on each occasion, with consequent drop in temperature to normal. There were probably two large abscesses in this case. This patient has been seen recently for myocardial trouble; he is otherwise well and has been hod-carrying.

The amounts of emetine and quinine mentioned were injected through the trocar before withdrawing it from the abscess cavity. Case 2 is remarkable for the fact that there were abscesses of the left lobe of the liver and of the spleen, which were in communication and which were emptied at one aspiration. The splenic abscess did not refill, but that in the liver required subsequent treatment.

A NOTE ON A RARE FORM OF CONGENITAL CARDIAC ABNORMALITY.

BY EDITH F. WILLOCK, M.B. DUB., D.P.H.,
RESIDENT MEDICAL OFFICER, MANCHESTER BABIES' HOSPITAL.

THE interest of the following case lies in the peculiar cardiac condition present, which was associated with a duration of life of over three months.

The Case Described.

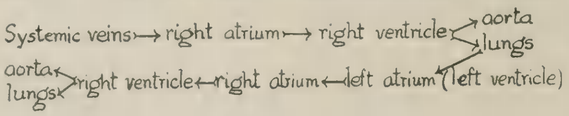
A male child, aged 3 months, was admitted into hospital as a "cardiac case." The history was that the infant's colour had always been bad, and that he had suffered from constant dyspnœa, which was greatly increased when fed; there had been no dyspeptic symptoms, but the child had not thrived normally. The family history was negative.

Condition on Admission.—The patient was a small wasted infant, who looked very ill; the colour was ashy grey, the eyes sunken, fontanelle depressed, respirations rapid and laboured, pulse very rapid and feeble, and temperature subnormal. Examination showed that the area of cardiac dullness was increased to the right of the sternum, the apex beat was displaced downwards and outwards, and a diffuse epigastric pulsation was present; on auscultation no cardiac murmurs were audible, and pulmonary examination revealed nothing abnormal.

Course of Case.—The infant was given two-hourly feeds of breast milk, which he took with great difficulty; when fed the colour at once became worse and slightly cyanotic, and the respirations grew very rapid and laboured; this distress gradually abated after the completion of the feed, but oxygen and brandy had to be administered during each meal, and occasionally camphor and strychnine given in addition. During the next few days the infant's condition improved slightly, and milk was taken with less difficulty. On the fifth day, however, the temperature rose to 101° F. and a cough developed; on examination of the chest a few râles were audible in the left axilla, and the breath sounds generally were harsh. On the following day the infant was much worse, the temperature rose to 104° that evening, and death occurred six hours later.

Post-mortem Examination.—There was an abnormal quantity of pericardial fluid present, and the heart itself appeared flattened from above downwards. The great vessels looked normal, except that the aorta was small compared with the pulmonary artery; the condition of the ductus arteriosus was, most unfortunately, not investigated. The right atrium was dilated and hypertrophied, and communicated with the left atrium through a patent foramen ovale; the right atrio-ventricular orifice was large with somewhat nodular valves, but was apparently competent. The right ventricle was greatly dilated and hypertrophied, while both aorta and pulmonary artery sprang from the conus arteriosus; no inter-ventricular foramen was present. The left atrium was small with a large auricular appendage; the foramen ovale was patent, and the left atrio-ventricular orifice was small and ring-like, with obviously functionless valves. The left ventricle was very small (about one-eighth the size of the right), and its only communication was with the left atrium through the atrio-ventricular orifice. The aorta originated from the right ventricle, commencing posteriorly and to the right of the pulmonary artery; it was somewhat small in size, but with normal valves. The pulmonary artery was large and normal as regards its valves. The lungs were congested, and showed evidence of slight bronchitis; the only other abnormality present was a complete mesenteric attachment to the whole of the large intestine. The blood from the systemic veins reached the right ventricle from the right atrium, its passage to the left atrium through the foramen ovale being prevented by the valvular formation of that opening. The right ventricle then drove the blood through the aorta and pulmonary artery to the systemic and pulmonary circulations. From the lungs the blood returned through the normal pulmonary veins to the left atrium, and thence by the foramen ovale to the right atrium, the left ventricle being merely an appendage of the left atrium and the left atrio-ventricular orifice functionless.

The schema of the circulation was as follows:—



Systemic veins → right atrium → right ventricle
aorta
lungs
aorta
lungs
right ventricle ← right atrium ← left atrium (left ventricle)

The heart was carefully examined for the presence of inter-ventricular foramina, but the inter-ventricular septum was complete and well developed. Evidence of the normal origin of the aorta was also sought for, and two or three shallow recesses were found in the left ventricle, in the region from which the aorta should have arisen; there was, in addition, an ill-defined recess in the right ventricle leading from the base of the aorta, backwards and to the left, towards the small left ventricle; these were, however, only cul-de-sacs.

It is probable that the ductus arteriosus in this case was patent, since, the pressure in the aorta and pulmonary artery being equal, the lungs would have suffered greatly from the high pressure, and the small aorta would have proved insufficient for the needs of the systemic circulation, had not such a safety-valve been present.

Commentary.

The most interesting points in this case were, therefore, as follows. The inter-ventricular septum was complete, showing no defects at all; the left ventricle communicated only with the left atrium, of which chamber it was merely a recess; and the aorta and pulmonary artery both sprang from the conus arteriosus of the right ventricle. To attempt to explain these anomalies it would appear necessary to assume an almost complete failure of development of the proximal bulbar septum, with secondary closure of the resultant defect in the inter-ventricular septum, the two ventricles being thus completely separated. The patent condition of the foramen ovale is a less rare occurrence, but it is interesting to note that in this case the blood passed through the aperture in the reverse direction to that of the normal fœtal stream.

There are a few cases on record which somewhat resemble the one described above. Keith[1] described a similar condition, but the infant only lived for two days; the cardiac malformations consisted of stenosis of the aorta, obliteration of the left atrio-ventricular orifice and left ventricle (traces only of this chamber remaining), a small left atrium, a patent foramen ovale, dilated right ventricle, patent ductus arteriosus, and partial transposition of the great vessels. Dudzus[2] collected records of a series of congenital cardiac abnormalities, three of these in particular (those of Jost, Theremin, and Spolverini) show a marked similarity to the case recorded here. The condition I have described is, according to Abbott in Osler and McCrae's "System of Medicine," one of the rare cases of true cor triloculare biatriatum, showing two fully developed atria, a patent foramen ovale, a single functioning ventricle from which both great vessels spring, and a rudimentary left ventricle which is merely a recess of the left atrium.

I am greatly indebted to Dr. Nesta Perry for her permission to publish this case.

Medical Societies.

LIVERPOOL MEDICAL INSTITUTION.

A pathological meeting was held on Dec. 6th. A number of specimens were shown and a short discussion followed.

Prof. E. Glynn, in association with Prof. J. Hill Abram, communicated a note on a case of

Acute Miliary Tuberculosis Complicated by an Anaerobic Infection.

The patient, a male aged 19, had suffered from "influenza" twice during the past year and pleurisy once. Weakness had been increasing for six weeks before admission and he died three days later, the temperature ranging from 103°–105° F. The lymph glands and spleen were enlarged, but there were no other signs except a systolic cardiac murmur at the apex. Blood cultures yielded *Staphylococcus albus* consistently. Red blood cells were 3,000,000 with a few megalo- and normo-blasts. The white cells were 12,000 per c.mm. with a preponderance of lymphocytes. At the post-mortem, 11 hours after death, the ileo-cæcal glands formed a mass the size of a hen's egg, were hæmorrhagic, and swarming with tubercle bacilli. They also grew *Staphylococcus albus*. All other lymph-glands were somewhat enlarged. There were gas bubbles in the portal system and large numbers of Gram-positive bacilli in the liver, which proved to be of the *B. aerogenes capsulatus* type. The liver showed typical caseating tuberculous nodules as well, and it contained hæmosiderin. The lungs showed a patch of grey hepatisation in which great masses of organisms resembling pneumococci were present. A similar case of miliary tuberculosis affecting mainly the mesenteric glands, but without *B. aerogenes capsulatus* infection, was described. This patient had not the anæmia of the pernicious type found in the former case. Of the four organisms found at death, the anaerobe was the most likely to have caused this anæmia. Other cases suggesting blood infection with anaerobes during life were quoted to confirm the speaker's opinion that in this case the anaerobe was present in the blood during life.

Prof. Hill Abram and Mr. J. T. Morrison believed the infection was probably terminal, the latter mentioning that the typical blood picture seen in aerogenes infection was not present.—Prof. J. M. Beattie thought that the multiplicity of organisms present might explain the rapid multiplication of tubercle bacilli.

Mr. Morrison read a short paper on the

Differentiation of Human and Bovine Tubercle Bacilli.

Alluding to the need for a reasoned consensus of opinion on this subject, he proceeded to sketch the differences recognised between the two types, and showed illustrative specimens of cultures and animal inoculations. Attention was drawn to the variations in results even in animal inoculations. Dean and Todd, and others too, had shown that Koch's original statement that animals could not be infected with human bacilli was not accurate. In the rabbit the results of inoculation were usually conclusive, but variations were also suggested that the number of organisms injected might materially influence the decision. With regard to the question of the stability of types the findings of the Royal Commission on Tuberculosis were quoted, and the importance of the exceptional cases pointed out, where by passage or culture definite changes in type had been produced. These observations supported the view of Besson and others that the two organisms were essentially one, to which view the author tended to adhere. At the same time in animal inoculation we had a means of determining with considerable accuracy the immediate source of the infecting bacillus, and on such conclusions it was justifiable to base public policy in the campaign against tuberculosis.

LONDON ASSOCIATION OF THE FEDERATION OF MEDICAL WOMEN.

A meeting was held on Dec. 11th at the Elizabeth Garrett Anderson Hospital, with Miss M. Chadburn the President, in the chair.

Dr. **Agnes Savill** read a paper on the

Sun Treatment of Tuberculosis at Leysin.

Dr. Savill said that a happy chance had led her, while enjoying a holiday in Switzerland, to visit the now world-famous clinic of Dr. Rollier, and spoke of the pleasant and inspiring experience that awaits any medical practitioner who attends the summer course of lectures and demonstrations there. Dr. Savill dealt with the subject mainly from two aspects. In the first place she gave a vivid description of the clinics (Les Frênes and the Châlets), making her hearers see in imagination the spacious balconies, the clear and artistic rooms, filled with the morning sun, the happy patients, the brown and laughing children playing naked in the snow, and emphasising above all the pervading spirit of human comradeship and cheerful helpfulness which pervades the whole organisation. In the second place she dealt with the more purely scientific aspect of the treatment. The physical properties of light were briefly discussed, with its bactericidal and chemical powers. It was pointed out that the ultra-violet rays, though apparently of low penetrating power, yet seemed of great therapeutic importance, and it was suggested that their wave-length might be modified by passage through the pigment-containing basal layers of the epidermis. That the good results are due to the sunlight itself rather than to the pure air and good conditions was indicated by the fact that the results seemed to be distinctly poorer in cloudy weather, and also that very severe reactionary effects could be produced by improper or careless dosage. A point to be emphasised was that light, like any other therapeutic agent, requires careful regulation, the dose being studied for the individual and based on the measurement of definite reactions (e.g., rise of temperature, dermatitis, exhaustion, &c.). It was worthy of note how health was maintained by the action of the light alone, the patient being entirely at rest and no massage being used. Dr. Savill also dealt with the various artificial substitutes for sunlight, which could be used in this country. The principal ones discussed were the carbon arc lamp, which was giving good results at the London Hospital at the present time, the mercury-vapour lamp, and the tungsten arc, this last giving the greatest proportion of ultra-violet rays and requiring therefore short exposures. In conclusion, Dr. Savill emphasised the need for accurate dosage of sunlight, for a pure atmosphere, and for a lengthy treatment, if a successful result was to be obtained.

Discussion.

Dr. **Kate Platt** read some notes sent by Dr. **Florence Stoney** on several cases she had treated at Bournemouth with good results.—Dr. **Charlotte Brown** said that her experiences at Leysin confirmed Dr. Savill's, and dealt with the sun treatment in England, when supplemented by arc-lamp treatment in the winter.—Dr. **Helen Mackay** spoke of the experimental side of the question of the action of light and described her experiences in the investigation and treatment of rickets, both in Vienna and London.—Miss **Ida C. Mann** described a case of Dr. Rollier's which she had followed, and discussed the results of the treatment at present being obtained at the Royal Sea Bathing Hospital, Margate, which she had had the opportunity of visiting.—Dr. **Lucy Nash** inquired as to the cost of substitutes for sunlight.—Mrs. **Handley H. Read** asked whether treatment by light had any action on pyorrhœa alveolaris.

The questions of the relation of impure air to tuberculous cervical adenitis, and the advisability of improving the health of the school child in this respect, and also the practical side of treatment and prophylaxis in England, and the type of patient most likely to be benefited by treatment, were discussed by various speakers, among whom were Dr. **Octavia Lewin**, Dr. **M. Dobbie**, Dr. **L. M. Potter**, and Dr. **C. A. S. Fitter**.

EDINBURGH OBSTETRICAL SOCIETY.

A meeting of this Society was held in the New Gallery, Edinburgh, on Dec. 12th, Prof. B. P. Watson, the President, being in the chair.

Exhibition of Specimens.

The following specimens were exhibited :—

Dr. **William Fordyce**: Large fibroid tumour of cervix, weighing 16½ lb. at time of removal.—Dr. **J. Lamond Lackie**: (1) Uterus with multiple fibroids, removed after expulsion of a four months' fœtus; placenta in situ. (2) Uterus with multiple fibroids; Cæsarean section done in full-time pregnancy. Hysterectomy performed on account of pain.—Dr. **W. F. T. Haultain**: Fibroid tumour simulating a horn of a bicornuate uterus.—The **President**: (1) Uterine fibroid with sarcomatous change; (2) uterine fibroid with carcinomatous invasion in a patient with carcinoma of vulva and of cæcum; (3) fibroid pushing cervix up on to the pubis removed at fifth month of pregnancy; (4) dermoid tumour of ovary with twisted pedicle simulating pelvic abscess and removed per vaginam.

Dr. **F. J. Browne** read a paper on the

Induction of Labour by Quinine and Pituitrin.

He began his address by referring to the researches of Oliver and Schafer, Dale and Blair Bell concerning the discovery of the drug and its action in causing uterine contraction, and went on to speak of the investigations of Fries, Haugh and Meyer, Stein and Dover, Cron and of B. P. Watson in inducing labour by its agency. In 1922 Watson had published the results obtained in a series of 195 cases, in 90 per cent. of which labour was induced with no maternal mortality and a fœtal death-rate of 6 per cent., nor could any of these deaths be fairly attributed to the use of pituitrin. The present communication was based on a series of 44 cases. Most of these had suffered from purulent vaginal discharges, and were therefore unsuitable for mechanical methods of induction. The technique employed was that advised by Watson. The indications included disproportion at term, primiparity, post-maturity, toxæmia, and hydramnios; 27 of the patients were primigravidæ, the others multiparæ; 23 of the patients were at term, three were post-mature according to the estimated dates, and 18 were premature. Out of the 44 cases, 40 were successful—i.e., a little over 90 per cent. All the failures occurred in cases where premature labour had been attempted. With regard to the time taken to start and complete labour, counting from the first dose of quinine, the average time taken till the onset of labour averaged 29 hours, and the average duration of labour was 16 hours. In the premature cases the average time taken till the onset of labour was 39 hours, and the average duration of labour nine hours. In spite of the numerous objections urged against the use of pituitrin for this purpose, the only misfortunes the speaker had experienced were two cases of tetanic contraction of the uterus. In both cases the spasm was effectually controlled by chloroform, but in one case the child was stillborn. While 26 of the patients had suffered from purulent vaginal discharges, only three patients showed a rise of temperature in the puerperium, and in no case was this prolonged into a second day. In four cases the child had been stillborn; in only one case, however, the case of tetanic contraction referred to, could this be attributed to the use of pituitrin.

Dr. **Fordyce** read the notes of a case of rupture of the uterus, following the administration of pituitrin for the induction of labour. A discussion followed.

Reviews and Notices of Books.

HISTORY OF THE GREAT WAR.

Medical Services: General History. Vol. II. By Major-General Sir W. G. MACPHERSON, K.C.M.G., C.B., LL.D. London: H.M. Stationery Office. 1923. Pp. 510. 21*s.*

THE second of four volumes on the General History of the Medical Services, forming part of the official medical history of the war, is exclusively the work of Sir William Macpherson, as was the first volume on the general history published two years ago.[1] There remain two volumes of general history, which have been prepared, though some time will elapse before they can be published. These will close the series apart from the volume on Statistics, which is being undertaken by the Ministry of Pensions. The present volume deals with the medical services of the British Expeditionary Force in France and Belgium down to the Battle of Loos, and has been compiled entirely from war diaries, including diaries of the administrative medical services, and from official despatches. At the outset of the campaign, without carefully prepared schemes and organisation, so as to ensure the rapid collection and evacuation of the wounded, confusion and delay were inevitable, and here the importance of administration in the employment of the medical services in war is emphasised. During the earlier operations, while the work of organisation was going on, the field medical units of divisions were most in evidence; for until the Expeditionary Force had been formed into armies, each with casualty clearing stations and motor ambulance convoys allotted to it, it was difficult to carry out schemes for methodically receiving and evacuating sick and wounded. But in the succeeding years the casualty clearing stations became the chief centres of the medical work with the field armies, and " when put to the practical test of war " fully justified their description in the field service regulations as " the pivot on which the whole system of collecting and evacuating sick and wounded turned." Hence the chapters on the later battles emphasise more the strategical employment and work of those units than the tactical employment of the field ambulances, which were acting under divisional control along normal lines.

The volume contains a number of illustrations and many carefully prepared charts and plans. Six large maps, unbound, are included in a pocket of the cover. It is understood that separate histories of the Medical Services of the Dominion Contingents are in course of preparation.

TEXT-BOOK OF CLINICAL PERIODONTIA.

By PAUL R. STILLMAN, D.D.S., and J. O. MCCALL, A.B., D.D.S. New York: Macmillan Co. 1922. With 79 Illustrations. Pp. 240. 16*s.*

FOR the benefit of the English reader unversed in the newer developments of dental terminology in America it may be as well to state that by " periodontia " is meant the branch of dentistry concerned with the treatment of " periodontoclasia." The latter term can be translated into the familiar words pyorrhœa alveolaris. While we may agree with the authors that this phrase is pathologically inaccurate, it is doubtful whether it can be replaced at this stage. Many strange words, indeed, appear in this book, such as " apoxesis " (the operation of scaling the teeth) and " ula " (the gum), and the authors find it necessary to devote a whole chapter to nomenclature. We deplore this invention of new and unnecessary words when others exist with the sanction of long usage. It darkens counsel and may, as Voltaire reminded us, conceal a poverty of thought.

In a book concerned with so elusive a disease as pyorrhœa, the chapters on ætiology are those likely to be first examined. The authors put forward some new hypotheses of considerable interest. They divide the ætiological factors into two—primary or inaugurating, and secondary or non-inaugurating. These two co-exist in a kind of symbiosis; neither alone can cause pyorrhœa. The primary causes are, according to the authors, almost entirely mechanical; the secondary causes are of various kinds, of which bacterial infection is only one receiving comparatively brief mention. Among primary causes the authors lay great stress on traumatic occlusion as an important factor in the production of pyorrhœa. Since this view was first put forward by P. R. Stillman, this book represents an authoritative account of his theory. The conception depends on the hypothesis that there is a normal occlusion of standard type; Stillman, following E. H. Angle, assumes a rigid and fixed type which may be considered the same for all cases. The orthodontist concerned with the correction of irregularities of the teeth is familiar with this hypothesis, but its application to the ætiology of pyorrhœa is a newer development. Such a view does not appear to allow any margin for biological variation. Traumatic occlusion as an ætiological factor in pyorrhœa seems therefore somewhat speculative. Gross deviations from normal occlusion often exist in pyorrhœic mouths, though not invariably, and may undoubtedly predispose to pyorrhœa by favouring the impaction of food. But Stillman goes much beyond this and considers that very slight deviations from the hypothetical normal can cause pyorrhœa. According to his argument, the impact of mastication on teeth not correctly aligned injures the periodontal membrane to such an extent that bacterial infection supervenes. Stillman advises that pyorrhœa should be treated by correcting the mal-occlusion, and this by grinding the surfaces of the teeth, so as to produce the same series of inclined planes which exist in normal occlusion. No very convincing proofs are offered in support of the theory, but it is claimed that this form of treatment is highly successful. Since the usual routine of scaling and medication is also carried out, it might reasonably be argued that improvement results rather from the last-named treatment.

There may be a wholesome kernel of truth in this theory, but the husk of conjecture seems disproportionally large, and we doubt if the obscurity surrounding the causation of pyorrhœa is much lightened by the theory propounded in this book.

SURGERY.

Elements of Surgical Diagnosis. Sixth edition. By E. P. GOULD, M.D., F.R.C.S., Assistant Surgeon, Middlesex Hospital; Surgeon to the Bolingbroke Hospital. London: Cassell and Co. 1923. Pp. 739. 12*s.* 6*d.*

THIS is a new and revised edition of a well-known manual. It maintains the standard of former editions. It is eminently readable, has a good index, and is of a handy size. It is likely to remain popular with the student beginning the study of clinical surgery.

A Text-book of Minor Surgery. Fifth edition. By E. M. FOOTE, A.M., M.D., Visiting Surgeon, St. Joseph's Hospital; Consulting Surgeon, Randall's Island Hospitals and Schools; Clinical Professor of Surgery, New York Polyclinic Medical School and Hospital. London: D. Appleton and Co. 1923. Pp. 845. 35*s.*

IN the preface to this book Mr. Foote points out that in the past few years many new ideas in the diagnosis and treatment of disease have been announced and tested. Some of them, like the Wassermann test of the blood and the intravenous injection of preparations of arsenic in the treatment of syphilis, have affected all branches of medicine. Others are purely surgical in character, and it is these which have been incorporated in the fifth edition of this popular text-book. The excellence of illustrations alone would account for this popularity, and the general get-up of the book is attractive. The section on blood transfusion needs to be rewritten entirely. Direct blood transfusion from one patient to another cannot be ranked as a minor surgical procedure, and, moreover, it is not justifiable, in view of the other simpler and more reliable methods. In most other respects the book is adequate for its purpose, which is to apply to the less serious everyday problems of surgical practice the new knowledge which the discoveries of the last 20 years have revealed.

Orthopædic Surgery. Seventh edition, thoroughly revised. By ROYAL WHITMAN, M.D., M.R.C.S., F.A.C.S., Surgeon to the Hospital for the Ruptured and Crippled, New York, &c. With 877 engravings. London: Henry Kimpton. 1924. Pp. xii. + 993. 42*s*.

DR. Royal Whitman seems rightly determined to keep his treatise on Orthopædic Surgery up to date, for he has this year brought out a seventh edition. We noticed the sixth edition in THE LANCET (1919, ii., 19), and it is therefore only necessary now to note the changes which have been made in the new edition of this well-known work. In the first place, a few of the old illustrations have been omitted, but a number of new ones have been added, so that there are now 877 instead of 767. The additional figures are distributed throughout the book, but the principal changes are to be found in the chapters on the treatment of the deformities following upon anterior poliomyelitis in which operations of tendon transplantation are fully illustrated. The operation of arthrodesis of the foot and ankle, which is so well known under the author's name, is illustrated by some new photographs. The section on the treatment of fracture of the neck of the femur in adults is expanded and transferred, without reason assigned, to the chapter on Collateral Orthopædic Surgery, which takes the place occupied in the sixth edition by that on Military Orthopædic Surgery. Under this new chapter heading are included the treatment of fractures, operations of reconstruction or arthrodesis of the hip-joint, and some of the subjects which were formerly included in Military Orthopædics.

It is unnecessary to say much about a book which has become so well known, but we may hazard the opinion that this standard treatise has been brought so thoroughly up to date as to make it one of the most complete works on orthopædic surgery in the English language.

MCNALLY'S SANITARY HANDBOOK FOR INDIA.

Sixth edition. Rewritten by Major A. J. H. RUSSELL, M.A., M.D., Director of Public Health, Madras. Madras: Government Press. Pp. 472. R.4.8.

THE appearance of this well-known handbook, now revised and rewritten by Major Russell, affords useful evidence of advance in Indian sanitation, and its contents incidentally throw much light on British sanitary problems. The book is well written, readable, and we heartily commend its perusal to public health students in this and other countries desiring to view the chief problems of public sanitation from an Eastern standpoint.

The subjects are dealt with on similar lines to those followed in other text-books on public health. The information given under certain headings is elementary, as befits a book for consumption by Eastern students; but the main principles are clearly stated in the light of recent research, and we have failed to discover any error of fact or inference, except possibly the remarks on page 357 on the prevention of syphilis; here it is definitely stated that the inspection and treatment under the Contagious Diseases Acts in this country were definitely beneficial, and an opinion is expressed that regulation of prostitutes by law has been of obvious benefit in many European states. Both of these statements are highly debatable. The chapter on foods is very full, and includes a section giving a useful summary of our knowledge on accessory food substances. The importance of milk as a food is stressed, as in India it forms the sole animal food of Brahmins and some other castes. The Indian cow gives only about a quarter of the milk yielded by an English cow, the difference probably being due in the main to the deficiency and poor quality of the food supplied to the Indian cow. Raw milk is very rarely used in India; but that the apparently small amount of non-pulmonary tuberculosis in India is not thus explained is indicated by the statement on page 355 that in Madras Presidency it is very rare to find a tuberculous animal in a slaughter-house.

Parasitic diseases are very prevalent, especially ankylostomiasis. Special investigations in the last three or four years have shown that the infection-rate of the population varies from 99 per cent. in wet districts to between 30 and 40 per cent. in dry districts. It is almost universal in the coolie classes working on tea and coffee estates. We note a useful practical point in protecting coolies who will not wear boots against hookworm disease—viz., to make each man, before going to work, step into a vessel containing tar, so that the legs are coated with tar up to the knees. Apparently no instances of dermatitis have been recorded. The difficulty of protecting natives against this disease, even in cities, may be appreciated from the statement that in Madras city 20 tons of fæcal matter are estimated to be deposited daily in unauthorised places all over the town, and there allowed to remain. Ingenious use is made of ancient Indian teaching on various topics, as that Vishnu laid down a heavy fine for the pollution of drinking water. So in advising against immature marriages orthodox Indians are commended to observe the teaching of the seer who stated that a young man should not marry until he becomes a grihastha—that is, when he is about 24 years old.

The student or health officer who reads through this sanitary handbook will be impressed by its mastery of the essential principles of hygiene and public health, and by the excellent manner of presentation and discussion of each subject.

INDUSTRIAL OPHTHALMOLOGY.

L'hygiène de l'œil et le travail industriel. Problems of Industrial Illumination. Geneva: International Labour Office of the League of Nations. 1923. Pp. 160. Fr.3 (Swiss).

THE subjects dealt with in this useful brochure are as follows: The comparison of various sources of natural and artificial light, the minimum amount of light required for various employments, and the methods whereby it can be measured; ocular fatigue and its prophylaxis in different employments, its bearing on progressive myopia and on miners' nystagmus; industrial accidents due to deficient illumination; and lastly, a comparison of the regulations in force in different countries whose object is the minimising of ocular fatigue in industrial employment. This volume affords a useful summary of the present stage of knowledge and practice in all these subjects. Its value is enhanced by a bibliography containing a list of papers on these subjects by English, American, French, German, and Swiss writers.

CHEMISTRY.

Systematic Organic Chemistry. Modern Methods of Preparation and Estimation. By WILLIAM M. CUMMING, B.Sc., F.I.C., I. VANCE HOPPER, B.Sc., A.R.C.Sc.I., F.I.C.; and T. SHERLOCK WHEELER, B.Sc., A.R.C.Sc.I., A.I.C. London: Constable and Co., Ltd. 1923. Pp. 535. 25*s*.

A CRITICISM which may justly be levelled at the majority of books dealing with practical organic chemistry is that they have been written with a complete disregard for any considerations of practical importance in technical production. To meet this criticism the present authors, all of whom have had both academic and industrial experience, have emphasised the necessity for considering the cost of the process and materials employed in the production of any given compound and have further introduced several manufacturing methods on a laboratory scale. They have, moreover, very wisely included a few operations involving the use of "oleum" in view of the industrial importance of this material.

The book opens with a useful chapter containing cautions with regard to the dangers of fire, poison, and accidents, and simple methods of dealing with the latter and other general advice to students; the second chapter deals at some length with a variety of apparatus which should be contained in a well-equipped laboratory. The second part of the book is divided into 30 chapters dealing with the actual preparation of specific compounds. The arrangement here adopted is novel and has much to recommend it; the general principle has been to divide the preparations and the headings of linking of carbon to carbon or hydrogen, sulphur, nitrogen, &c., each group being further systematically subdivided. Part III., composed of ten chapters, deals with quantitative measurements and estimations of groups, &c., while Part IV. is devoted to the preparation of a number of inorganic compounds required for the production of some of the organic compounds described in Part II. The authors have kept before them the intention of showing the student the close connexion between the lecture-room and the laboratory by accompanying each new reaction mentioned by a practical experiment to illustrate it, and have thus compiled a valuable book containing a large variety of organic preparations. The practical instructions are throughout clear and intelligible and references to original literature are repeatedly given. The book should be welcomed by teachers and students as a valuable addition to the practical text-books of organic chemistry.

Kurzes Lehrbuch der Chemie in Natur und Wissenschaft. By Prof. Carl Oppenheimer, Ph.D., M.D. Leipzig: Georg Thieme. 1923. Pp. ix. + 258 + 862. 29*s.*

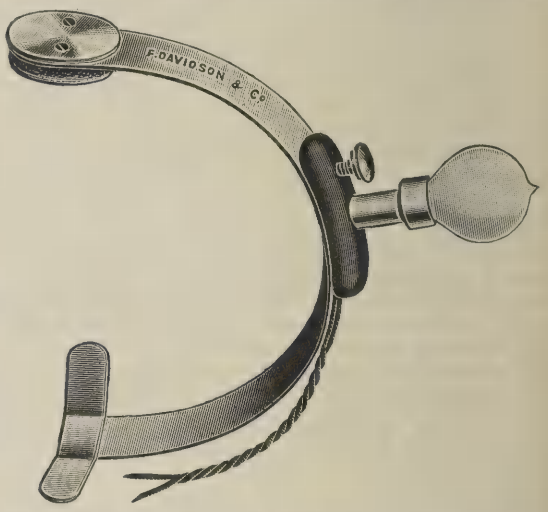
There is nowadays hardly a branch of pure or applied science which does not, sooner or later, require the assistance of chemistry for the further elucidation of its problems, but unfortunately not all workers have chemical equipment requisite for further progress. It thus happens that there exists a large body of what may be described as chemical amateurs who, through force of circumstances, have acquired an interest in chemistry when it is too late to take up a complete study. For these a book such as Prof. Oppenheimer's may supply a want, since it attempts to compress into one volume the whole subject of chemistry in potted form. The introduction to general chemistry has been entrusted to Prof. Johann Matula, who deals ably with a wide range of subjects which include, among others, radio-activity, atomic structure, X ray spectra, colloids, valency, coördination numbers, thermodynamics, electro-chemistry, &c., the whole being treated in an up-to-date and readily intelligible manner. The second part, devoted to inorganic chemistry and covering 318 pages, is by Prof. Oppenheimer himself, and by skilful interspersion of a number of facts of practical or of physiological interest he has invested the subject with an interest not commonly encountered in a text-book of inorganic chemistry. The perusal of this section might well be recommended to those who would like to see inorganic chemistry cut out of the syllabus of medical students. The third part, on organic chemistry, is in some ways perhaps the least satisfactory of the three; the author has here attempted an almost impossible task, and the subject is treated in too sketchy a manner to serve the needs of students.

As a book of reference for biologists and others the work may be recommended on the whole, since it contains a wealth of up-to-date biochemical information which has not yet been incorporated in text-books on biochemistry. It is stated in the preface that the book is addressed to biologists, pharmacists, medical men, and agriculturists, as well as to technical chemists who wish to obtain information upon subjects in which they are not themselves specialists; but the author furthermore claims that it should be of use to any educated person wishing to obtain an insight into the workshop of the chemist. Whether it is possible to write a text-book appealing to such a heterogeneous type of audience remains doubtful, but there can be no doubt that the compilation is a very readable one.

New Inventions.

PORTABLE LIGHTING APPARATUS FOR OPHTHALMIC WORK.

Some years ago, when commencing refraction work in schools scattered over the area of the county of Durham, I was forced to evolve a source of light that would be sufficient, reliable, and easily portable. Through the kindness of my friend, Dr. A. C. Norman, my attention was drawn to the desirability of using electric light supplied by an accumulator. I have gradually improved on the original, and the improved instrument is shown in the illustration. A polished metal spring head-band, with an eight candle-power frosted lamp at its centre, is placed across the child's head from occiput to forehead. This lamp is connected by eight feet of flex, with a four-volt accumulator which stands on the floor near the child. A threaded screw placed near the lamp makes or breaks the contact. The accumulator will give sufficient output for 100 average refractions. The eight candle-power lamp gives ample light. If it be desired to use the light for direct examination of the fundus or for inspection of the cornea, the metal band is lifted off the head, and thus one is able to hold the light in any position. Apart from its portability, the light when on the head has the advantage of moving as the patient moves—a considerable advantage where a restless child is concerned. At the Durham County Hospital I use this same lamp for all purposes, and I obtain current by attaching the terminals to a pantostat. Oculists who may be called upon to see private patients in houses where the light is not too accessible and where the electric ophthalmoscope does not give sufficiently intense illumination, will find this portable apparatus of considerable service.



Messrs. F. Davidson and Co., 29, Great Portland-street, London, W. 1, supply sets to medical men.

Durham.

THE LANCET.

LONDON: SATURDAY, DECEMBER 29, 1923.

GASTRIC ULCERATION.

The thoughtful surgeon has an inveterate conviction of the ephemeral nature of his work. He knows that there can be no finality in surgery until surgery is banished from the treatment of disease. Eventually, injury alone will demand the exercise of surgical skill. This change is slowly but surely taking place before our eyes. Not many years ago the excision of tuberculous cervical glands was amongst the commonest of operations performed in a London hospital; now it is almost a rarity. Improved methods of combating disease have allowed us to dispense with the resort to the knife. Dr. A. R. Neligan reminds us in this issue how, in the treatment of liver abscess, open incision is giving place to aspiration. The same revolution has taken place in the treatment of tuberculous joints, whilst it seems fairly safe to predict the elimination of surgery in the treatment of malignant disease when the secrets of this scourge have been revealed to scientific investigation. It is therefore to be accredited as a virtue, when a surgeon is found to relinquish an established method for one he finds more effective in accomplishing his purpose. These truths of surgery are driven home by Sir Berkeley Moynihan in two recent lectures on the Treatment of Gastric and Duodenal Ulcer.[1] "A physician doomed to practise surgery," as the author calls himself, Sir Berkeley Moynihan has brought an essentially critical mind to bear upon problems arising out of an experience of no less than 718 cases of ulceration of the stomach and duodenum, where the diagnosis was established by actual inspection on the operating table. The conclusions to which he has been impelled by sheer weight of evidence demand our attention and enforce our belief.

In the diagnosis of a gastric ulcer the author relies upon two things, the history of the illness and the radiographic examination. There is only one way of establishing the existence of an ulcer beyond dispute. It is to see it. X rays will often render the ulcer visible before the withdrawal of the "curtain of the anterior abdominal wall." As to the symptoms, there is a rhythm which is characteristic of gastric ulcer, another significant of duodenal ulcer, and a sort of rhythm of activity alternating with apathy, with a period lasting over weeks or months. Punctuality in the onset of pain or relief from it is of diagnostic import. In this series of cases, duodenal ulcer was encountered much more often than gastric ulcer, and Sir Berkeley Moynihan maintains that the latter is seldom within 2 inches of the pylorus and so does not commonly give rise to pyloric stenosis. Narrowing in this region is the result of extension of duodenal ulceration, a process which may go beyond the pylorus into the stomach itself, where a malignant change may supervene. It is possible at this stage to come to some conclusion of value concerning that difficult decision as to the efficacy of medical methods of treatment at our disposal. Medical treatment rarely leads to sound healing and demands such enduring care on the part of both patient and physician, that it becomes too irksome as a practical measure for those who must take part in the ordinary intercourse of the world. Sir Berkeley Moynihan, in cases where the only possible operation was a jejunostomy, has been able to watch the alteration in X ray appearances from time to time. He finds that healing, as evidenced by change of shadow outline, is always a matter of many months and in some cases of years. Neither is the disappearance of the niche, as seen by barium meals, always proof of healing. This fallacy was demonstrated by E. Hollander.[2] Many gastric ulcers resemble those intractable leg ulcers which repeatedly break down and persist until the end of life. It is without exaggeration to say that the medical mortality from perforation and hæmorrhage is vastly greater than that incidental to surgery, which in a very high percentage of patients leads to a permanent cure. In Sir Berkeley Moynihan's large personal series, there has been no operative death since 1912. There is one other argument brought forward to support the surgical attitude in the treatment of gastric ulcer, the belief that cancer arises in the simpler lesion. This does not carry the weight of the considerations set forth above, for a very competent group of pathologists deny the frequency of malignant degeneration on firm histological grounds. Cancer, according to them, does sometimes originate in the margin of an ulcer, but quite rarely.

However this may be, surgery seems definitely to have established itself as the only effective treatment for gastric ulcer. What should be the method of surgical attack is an almost equally vital question to decide. Opinion is not quite unanimous yet on this point. Sir Berkeley Moynihan has tried many procedures. Generally speaking, he has concluded that gastrojejunostomy is most widely applicable and effective in duodenal ulceration, whilst excision of the pyloric segment of the stomach with lateral implantation into the jejunum by the "no-loop" method, devised by himself, is almost ideal in the treatment of the gastric lesion.

◆

INSANITY ON ARRAIGNMENT.

Of the minor points arising out of the recent report of the Committee which has been considering the legal effects of insanity in criminal trials there was one—not covered by our recent summary—which has not had to wait long for illustration. A young man was found guilty of the murder of a woman in a taxi-cab in the Brompton-road. There had been a preliminary question of his fitness to plead to the charge. Dr. W. N. East, senior medical officer of Brixton Prison, expressed the opinion that the man was unfit to take his trial. Mr. Justice Avory, however, with some remarks upon the divergence between medical and legal views, instructed the jury that, if the man was able (as he seemed to be) to follow what was going on in court, they could say that he was fit to plead. The jury found him fit to plead, and the case proceeded, with the result already stated. We alluded to this case more in detail under the heading of Medicine and the Law, and need only note here that the divergence of opinion to which the judge referred was merely the notorious difference between legal and medical conceptions of insanity. Had the jury found the man unfit to plead, his subsequent treatment would have occasioned a further divergence of opinion which is worth examination.

---

[1] Gastric and Duodenal Ulcer. By Sir Berkeley Moynihan. Bristol: John Wright and Sons, Ltd. 1923. Pp. 48. 2*s*. 6*d*.

[2] Jour. Amer. Med. Assoc., 1923, lxxx., 29.

Before the stage is properly set for the drama of a criminal trial there are three important preliminaries. The first is the arraignment of the prisoner—i.e., the bringing of him *ad rationem*, to a reckoning, by reading the indictment to him. The second is his plea, which, with certain technical exceptions, is either "Guilty" or "Not guilty." The third, if he pleads "Not guilty," is the joining of issue between him and our Lord the King, that issue which the jury is summoned to try. But if the prisoner is insane, if the arraignment means nothing to him, and if he cannot make his plea to it, there is a deadlock. There may therefore be a preliminary issue as to his sanity. Upon his arraignment either the prosecution or the defence is allowed to raise the question of the prisoner's fitness to plead. Then if he is found insane by a jury impanelled for the purpose, so that he cannot be tried upon the indictment, the court must direct this finding to be recorded and the accused to be kept in custody till His Majesty's pleasure be known. This procedure is ordained by Section 2 of the Criminal Lunatics Act of 1800, an Act passed after the trial of HADFIELD for shooting at King GEORGE III. in Drury Lane Theatre. The point the jury has to decide is whether the accused is insane at the time of the arraignment, not at any other time. The test laid down by judges in the past is whether he is of sufficient intellect to comprehend the course of the proceedings so as to make a proper defence, to challenge a juror to whom he might wish to object, and to understand the details of the evidence. The result of a finding of insanity on arraignment is that the prisoner, who may be entirely innocent of the crime, is forthwith treated as if he had been found guilty but insane, and is sent to a criminal lunatic asylum. It is at this point that the medical and the legal views seriously diverge. The Medico-Psychological Association, emphasising the injustice to a possibly innocent man, suggests that in these cases a plea of "Not guilty" should be entered, and that the trial should proceed, arrangements being made for representation of the interests of the accused. The British Medical Association recommends that persons found unfit to plead should have a right under proper conditions to apply to a High Court judge for an order that the issue of fitness to plead should be re-tried. To this the report of the recent Committee replies that, if a man is insane, it is a burlesque to proceed with his trial: that the standing orders of the Prison Commissioners (which recommend that a prisoner be left to stand his trial unless there are strong reasons to the contrary) represent the present practice and are satisfactory; that a prisoner should not be found unfit to plead except upon the evidence of at least two doctors; and that from a finding of insanity upon arraignment there should be no appeal.

We are left, therefore, in the improper and indefensible position that in these cases a possibly innocent man—or rather a man deemed innocent by law because not yet found guilty—is put away, perhaps for life, in a criminal lunatic asylum. If his relatives complain, the legal answer seems to be that usually in these cases, if the man recovers and is tried, the result is a verdict of "Guilty but insane." This is an odd perversion of the doctrine of the presumption of innocence. It is perhaps worth adding that, as the trial proceeded in the taxi-cab case, a considerable volume of evidence as to insanity was adduced without effect. The same remark might be made of another case also tried lately at the Old Bailey, in which an unhappy woman was found guilty of murdering her four-months-old illegitimate child by strangling it, and afterwards throwing the body into a brook. It was proved that her father and aunt had been certified lunatics, that an uncle had also been confined in an asylum, and that the prisoner herself was mentally deficient. She was not insane, however, in the eyes of the law. This latter case was labelled in the press as one of infanticide. In a popular sense it was; technically it was not. It may be remembered that under the Act of 1922, which created the new legal offence of infanticide, a more lenient punishment can be awarded when a woman causes the death of her newly-born child, "but at the time of the act she had not fully recovered from the effect of giving birth to such child, and by reason thereof the balance of her mind was then disturbed." The fact that such an Act should have been necessary is in itself a condemnation of the legal treatment of insanity in criminal trials.

◆

STRAINS OF THE DIPHTHERIA BACILLUS.

SUBDIVISION within the species into varying numbers of serological strains is being gradually extended to embrace a very large number of pathogenic organisms. Sometimes the matter is of great practical importance in treatment, since sera potent against one individual may be useless against another. This holds particularly with the pneumococci, but is of much less importance with a toxin-producing organism, such as tetanus, which seems to produce the same toxin, neutralisable by one and the same antitoxin, whatever be its serological type. The matter stands similarly with regard to another toxin-producing organism, the diphtheria bacillus. It has comparatively recently become recognised that this organism, too, can be split into groups on the grounds of their agglutinability with single sera prepared from a number of single strains. Dr. W. M. SCOTT[1] has recently investigated this now well-established fact, with special reference to the status of those organisms which, though closely allied to the diphtheria bacillus, have been excluded from the pale by most human bacteriologists on the ground that they do not produce toxin. He has also studied the question of the special activity of one or other of these serological strains in epidemics. Dr. SCOTT has compiled eight agglutinating groups which include 184 of his total of 265 strains, leaving 81 strains still unidentified. This well exemplifies the complexity of such a grouping, since to include the whole of these strains under serological headings would necessitate the formation of a very unwieldy number of groups.

The most interesting fact which emerges from this classification is that the majority of bacilli obtained from actual cases of the disease fall into one set of groups, whilst in the "carriers and contacts" there is a marked shift of the distribution into another set, which latter occur only in a small minority of actual cases of the disease. Likewise the percentage of unidentified strains, which is only 13 in the acute cases, rises to 30 in convalescents, and 51 in the contacts and carriers. These facts can only mean, so it seems to us if we accept the usual carrier conception, that the serological type changes in convalescence or in transference to another host. It would be interesting to have included an analysis of the distribution of such bacilli in normal persons who have not been in special contact with diphtheria cases. It must, if this interpretation be true, also follow that where such a carrier infects a fresh subject the organism must revert to one of the serological groups which predominate in the acute disease. This matter is one of great importance in any consideration of the rôle of the carrier in diphtheria. Either these extraordinary mutations occur, or the importance of the carrier has been misconceived, or the observations are incorrect; and we have no reason for believing that the last alternative is the correct one. Dr. Scott includes within his group non-toxin-producing strains which cannot be excluded by ordinary morphological and cultural characters. If the agglutination characters of the bacilli are as labile as the forementioned considerations would suggest this does not seem quite justifiable. After reading his paper, and in view of Hartley's showing that all pathogenic diphtheria bacilli produce the same kind of toxin, we are more satisfied than ever that the only satisfactory final criterion of the diphtheria bacillus, not for clinical diagnosis but for practical bacteriological differentiation, is its ability to produce toxin.

Annotations.

"Ne quid nimis."

ALCOHOL INJECTIONS FOR NEURALGIA.

At a recent meeting of the Section of Otology of the Royal Society of Medicine Mr. Arthur H. Cheatle showed three patients who had sustained damage to the ear following the injection of absolute alcohol through the face for the cure of neuralgia. In two there was injury to the middle ear and in one to the auditory nerve. The first was a man aged 71, who had severe deafness and some discharge from the left ear immediately after the injection a year previously. He did not have pain, giddiness, or tinnitus, but there was temporary paralysis of the facial nerve. The second case was that of a man aged 72, who, following a similar injection two years previously, had severe deafness, tinnitus, and a slight discharge. There was no giddiness, pain, or facial paralysis. The neuralgia was cured. No doubt in this case the alcohol entered the Eustachian tube and reached the middle ear. Both these cases had a general anæsthetic for the operation, and Mr. Cheatle pointed out that if it were done under local anæsthesia, according to the custom of Dr. Wilfred Harris, the patient could give warning of anything wrong. The third case was that of a woman aged 22, who had complete deafness on the left side following the spirit injection under a general anæsthetic nine months previously. There was also immediate giddiness and paralysis of the sixth and seventh nerves. She had been very ill in bed for five months, and her neuralgia was not cured. Subsequently, the Gasserian ganglion was removed; this cured the pain, but entailed the loss of an eye. Apparently the spirit had reached the subarachnoid space and directly injured the sixth, seventh, and eighth nerves. In all the three cases the injection was carried out by experts. At the same meeting Mr. T. B. Layton described a case in which the injury produced on a middle-aged man by injection of alcohol for the same purpose was much more severe. He had lost the left eye, and on the right he had corneal ulceration; he spoke in a high falsetto voice, and he was very deaf. The left side of his face was paralysed. In all he had had ten injections, most of them in the Far East. Mr. Sydney Scott, the president of the section, said he had heard of such cases but had not seen any. He had used absolute alcohol for destroying the internal ear. As the spirit spread rapidly, it was necessary to use only a minimal quantity so that none was allowed to reach the middle ear. The measure was only carried out by him in extreme necessity. Sir William Milligan said he had not much experience of these injections, but he knew of cases in which they had done irreparable damage, some in which it had been necessary to remove an eye. Relief in some cases he knew of lasted from 9 to 18 months, but others gained no relief by it at all.

The avoidance of accidents when alcohol is injected for the cure of trigeminal neuralgia deserves close attention. Pricking the Eustachian tube should be a well-known danger to those accustomed to giving such injections. Under local novocaine anæsthesia the patient will always complain of a pain deeply situated in the ear if the needle reaches the Eustachian tube, and when this occurs the needle should be withdrawn about an inch and then pushed slightly forward. Novocaine probably does no permanent injury if injected into the Eustachian tube, and if the rule be scrupulously followed not to inject spirit until anæsthesia results from the preliminary novocaine, no harm will come. Thus to secure safety under general anæsthesia, novocaine alone should be injected in one spot only, and the patient allowed to come round sufficiently for testing the two sides of the face with a pin, while the injecting needle is left in situ. If the desired anæsthesia is found to have resulted, then the alcohol syringe is fitted on and the injection completed, a further whiff of general anæsthetic being given if thought desirable. If no anæsthesia has resulted from the novocaine, then no spirit should be injected, but a fresh search made for the nerve. Usually it is unnecessary to give much further anæsthetic for this. The practice of making a rapid injection in the direction of the foramen ovale under a general anæsthetic, and assuming that by doing so one has injected the third division of the trigeminal nerve, is to be rejected. The procedure is not by any means so easy that it can be done without care, but the nerve is there to be found if the operation be conducted with patience and deliberation, and there should be practically never any failure. In the third case described by Mr. Cheatle the catastrophe appears to have happened after the needle had penetrated the foramen ovale in the endeavour to inject the Gasserian ganglion under general anæsthesia, the sudden injection of a quantity of alcohol into the subarachnoid space causing widespread and permanent paralysis of cranial nerves. Had the injection been done a few drops at a time, after letting the patient come round partially from the anæsthetic, the operator would have been warned of danger by the appearance of nystagmus, vertigo, and commencing facial paresis. Then with the cessation of the injection the symptoms would almost certainly have passed off in a few minutes or an hour at most. The duration of relief from the neuralgia is, we would suggest, better than Sir William Milligan suggests. In an article on the technique of these injections contributed to our columns [1] last year Dr. Wilfred Harris states that freedom from the neuralgia may practically be guaranteed for 12 months if the nerve has been properly hit, and in the majority of his cases the immunity from pain was much longer, ranging up to 13 years in one case. Four and five years was a common period for the immunity to last in his experience. In the Gasserian injections there is no reason why permanent relief should not be expected, the anæsthesia obtained being as complete as that after Gasserectomy.

MEDICAL MILITARY PREPAREDNESS.

Military medicine will never flourish unless the medical student becomes interested in it during his years of training. In the November issue of the *Military Surgeon*, the first number entirely edited by Major E. E. Hume, U.S.M.C., an active service officer, the best way of training the medical student to understand the work of the military medical officer is discussed by Lieut.-Colonel H. H. Rutherford. He thinks this can be done, in spite of the already crowded time-table, if he can get specially good instructors, a very high-class text-book, and is allowed to pick only high-grade students for the course, which will occupy 240 hours in the early years and a spell in camp at the end of the last year. In the same issue Major L. H. Bauer, Commandant of the School of Aviation Medicine, sketches the training given to the reserve medical officers of the U.S. Air Service. They are divided into three classes—flight-surgeons, examiners, and specialists. These all belong to the outside profession; they are busy men, and while they must be instructed, it is most important that their time shall not be wasted; accordingly the first class are given two correspondence courses through two winters, with a short basic course of practical work in the summer. The first winter's course deals with the eye and ear, the heart, and neuropsychiatry; the second course develops these subjects further and takes the student over Air Service administration, all this by correspondence, but everything is gone over again, practically, in the summer basic course. It is felt that the reserve officer will now be a better practitioner than before, and, if he passes the examination after the first year, he will be allowed to make the physical examination for flying, and having passed after the second course will be rated flight-surgeon. Selected officers will have a six weeks' training at the Aviation School. Those who succeed will be qualified as examiners. The third class are research workers, physiologists, eye specialists, and the like, who will be called to act as instructors in the school. It is hoped that "by the time of another emergency" America would have flight-surgeons, physical examining units, and specialists ready to step in and aid in the rapid expansion of the Air Service. In a third article Colonel G. M. Blech, one of the founders of the Medical Officers' Reserve Corps, explains to young members, already highly educated doctors, why they should interest themselves in learning something of tactics, how much more useful that knowledge will make them in battle, and how easily the necessary knowledge may be acquired. The whole number is full of the need for preparedness.

INTERNATIONAL CONGRESS ON INDUSTRIAL HEALTH.

A group of Swiss medical men interested in industrial health questions met at Berne last October and constituted themselves as the Swiss Organising Committee for an International Congress on Industrial Health to be held at Geneva from July 18th–20th, 1924. The committee consists of Prof. W. von Gonzenbach (Zurich), Prof. W. Silberschmidt (Zurich), Prof. H. Zangger (Zurich), Dr. A. Rossi (Lugano), Dr. H. Carrière, Director of the Public Health Service, and Prof. H. Cristiani (Geneva), the last named being chairman. This first congress will deal with the following questions: industrial lighting and eyestrain; impure air in factories; the value of fatigue tests. The committee has asked prominent men of science who have given special attention to these questions to draw up reports on them, and three such reports will be presented for each question. The office of the committee is at the Institut d'Hygiène of the University of Geneva, and all persons wishing to take part in the congress should communicate with the committee at that address, from which further information may be obtained.

ACTINOMYCOSIS OF THE HEAD AND NECK.

In a recent communication to the Pacific Northwest Medical Association, Dr. Gordon B. New and Dr. Fred A. Figi,[1] of the Section on Laryngology, Oral and Plastic Surgery of the Mayo Clinic, illustrated the frequency with which actinomycosis of the head and neck escapes recognition. They gave the following statistics. During the decennium 1913–22 inclusive 157 patients with actinomycosis were examined at the Mayo Clinic. In 107, or 68·1 per cent., the disease involved the head and neck, but only seven of these patients were being treated for actinomycosis at the time of their admission to the clinic. The disease is much commoner in males than in females, 98 of the 107 cases being in males. The ages ranged from 9 to 66 years, but the majority of the patients were in early adult life. As regards the method of infection, 45 out of 80 patients, or 56·1 per cent. from whom information could be obtained, stated that they had not come into contact with the disease in animals. The remaining 35, or 43·7 per cent., had been more or less closely associated with the disease in animals before they developed symptoms themselves. In no case was there evidence of direct transmission from one person to another. The clinical picture of actinomycosis of the head and neck varies according to the virulence of the infection and the amount of secondary infection. The commonest symptoms are stiffness in the region involved, pain, and swelling. The jaw may begin to tighten and even become completely ankylosed. Pain is sometimes severe, or may be completely absent until the mass breaks down. In some cases dysphagia may be an early symptom, especially if the base of the tongue or anterior cervical region is involved. Sore throat, stiffness of the neck, and earache are occasional symptoms. The activity of the process varies from a slow indolent condition, which takes months or years to reach its full development, to a fulminating one of a few weeks' duration. The commonest type is that of an indurated mass which breaks down forming multiple superficial abscesses. The disease is liable to be mistaken, as was illustrated in the writers' series, for malignant growth, tuberculous adenitis, osteomyelitis of the lower jaw, thyroglossal duct sinus, subperiosteal abscess, and tuberculous thyroiditis. The most important factor in the treatment is early diagnosis. In advanced cases intracranial extension may develop or the chest may become involved. In addition to iodides, which are almost specific and should be used in progressively increasing doses, radium has proved beneficial by causing a breaking down of the granulomatous masses and clearing up the induration. Surgical treatment consists in opening up widely all pockets, packing them with iodoform gauze, and swabbing the wounds with iodine. Of 85 cases which could be traced by the writers, 60, or 70 per cent., were well five years or less after their discharge, 7 were dead, and 18 were still under treatment.

OPIUM AND DYSPNŒA.

The term dyspnœa is one which is difficult to define exactly, but it may be taken to mean a condition in which the normal sequence, rhythm, and character of the acts of respiration are disturbed, whether subjectively or objectively. In the healthy subject, the normal control of respiration lies in the activity of the respiratory centre of the medulla. This centre is regarded as being capable of automatic activity and of sending rhythmic efferent impulses to the muscles that perform the movements of respiration. The activity of the centre is known to be affected by four influences which are independent of volition—namely, (1) the pressure of CO_2 in the blood supplied to the centre, (2) the H-ion concentration of the blood supplied to the centre, (3) the pressure of oxygen in the blood supplied to the centre, and (4) the afferent impulses reaching the centre, which may come from the higher centres, as shown in the effects of volition and emotion. Many investigators have worked on the problems presented by these several factors, and their results show that disturbances of the respiratory mechanism can result from (1) alteration in the CO_2-content of the blood supplied to the respiratory centre—increase in this content causes increased breathing, with acidæmia and raised CO_2 pressure; (2) alteration in the fixed acids in the blood, so that increase in the acids causes increased breathing, with acidæmia and lowered CO_2 pressure; and (3) alteration in the oxygen in the blood supplied to the centre, so that deficiency causes increased breathing, with alkalæmia and lowered CO_2 pressure. Oxygen-lack causes mainly increase in the frequency of breathing, while increased CO_2 pressure and increased fixed acids cause mainly increase in the depth of breathing.

Among the investigations reported on clinical cases of cardiac dyspnœa, each of these three types of chemical change has been found, plus dyspnœa due simply to mechanical causes, as œdema of the lungs. The whole subject was discussed by the Royal Society of Medicine on broad lines at a recent meeting of the Section of Therapeutics when Dr. Claude Wilson read a paper which we published last week. Dr. Wilson divides cardiac dyspnœa clinically into two distinct types: (*a*) Ordinary breathlessness as an immediate consequence of exertion, and (*b*) paroxysmal dyspnœa, subdivided into Cheyne-Stokes breathing and cardiac asthma, for the treatment of which latter type he recommends the use of opium. The indications for such treatment would appear to be borne out on physiological grounds by the data collected by Prof. F. R. Fraser, who introduced the subject in a comprehensive review of recent research in this field. Prof. Fraser quotes the investigations of many workers on differing clinical types of cardiac dyspnœa, and comes to the conclusion that, if the present explanation of the causes of dyspnœa is correct, then any treatment that is to affect the fundamental cause of the dyspnœa—that is to say, oxygen deficiency through stasis—must be directed towards improving the efficiency of the circulation. Administration of oxygen can only be useful when the arterial blood is deficient in oxygen. The rapid shallow breathing of cardiac dyspnœa is peculiarly ineffective in correcting the disturbance, as it permits of stasis in the bases of the lungs and deprives the respiratory movements of much of their value in aiding the circulation. The administration of morphia causes slowing of the respiration, with the result that, clinically, the circulation of the patient would seem to be stimulated and his general condition improved. Thus morphia apparently does more than simply check a symptom. In the treatment of paroxysmal dyspnœa with progressing œdema of the lungs, not only do the respiratory disturbance and distress diminish, but the œdema of the lungs may clear. If such paroxysms, with or without the development of œdema, are due to an exacerbation of the failure of the left ventricle, as seems most likely, then the essential cause of the dyspnœa will be the same as in simple cardiac dyspnœa—namely, oxygen-lack at the centre. This will result in lowering of the carbon dioxide pressure and alkalæmia, and since the dyspnœa continues, the centre must be acting at a lowered threshold to H-ion concentration. This is the conception of Haldane in the condition of oxygen-lack in healthy people. Morphia depresses the centre, so that it reacts at a raised threshold. The effect of treating cases of dyspnœa with morphia would therefore be to raise the threshold so that the centre reacts only to a higher H-ion concentration than before. This would have the effect of restoring the carbon dioxide pressure throughout the body and in the medulla to a more normal level. Prof. Fraser emphasised the need of carefully ascertained facts in the study of this condition, and concluded a valuable paper by laying down an important axiom. The use of drugs in order directly to affect the dyspnœa with benefit to the patient cannot be clearly understood until the conditions of the centre and the afferent impulses, and the actions of such drugs on the centre and on the afferent impulses, are elucidated.

POST-GRADUATE MEDICAL EDUCATION.

For some years past the need for greater facilities for post-graduate instruction has been recognised in this country, and various attempts have been made to remedy the defect. The Fellowship of Medicine is doing excellent work in providing access to the clinical teaching of the various London hospitals and in arranging a number of lectures for post-graduate students, while the West London and the Prince of Wales's hospitals are devoting all their clinical material to post-graduate teaching. But while these efforts do fill a very definite place, they are chiefly of use for the general practitioner, or for those who have only a very limited time at their disposal. Training for the specialist is still inadequate. E. P. Lyon[1] gives an interesting account of the way in which the problem is being solved in the University of Minnesota. The chairman of a committee on post-graduate instruction investigated how men became surgeons, urologists, oculists, and so forth.

> "He found, taking the good ones, that the chief method that has been used in the past and that is in use now is that they should serve as assistants in a good clinic for two, three, or more years. The doctor calls his helpers assistants; but from the young men's standpoint, they serve their assistantship for the purpose of becoming efficient in the speciality. Now our idea is that those young men be regarded as students and not as hired men. If you go to the Mayo Clinic or the University Hospital you will see young men working there. They will look to you like assistants, and they are assistants; but we take a different view regarding them. We say they are not the servants of the clinic, but primarily students. We call them Fellows. As soon as you make that slight transition in regard to your assistant, you have made a great difference in your attitude toward him and in his attitude toward his work. You lay out a man's programme not with reference, primarily, to how he can best help you, nor how he can best contribute to the efficiency of the hospital or clinic, but how you can best help him . . . You would hesitate to send an assistant perhaps to the anatomical or pathological laboratory, for three or six months and pay his salary; but we do not have any hesitancy in sending these men, if that is what they need."

Here we notice a vital difference between the method used in the University of Minnesota and that in vogue in any of the British medical schools, and the Mayo scheme might be worthy of the consideration of those responsible for post-graduate instruction on this side of the Atlantic.

OZÆNA AND DIPHTHERIA.

Dr. R. Kawano,[2] of the Vienna State Institute for Serum Therapy, alludes to the investigations of Beck and Brodt, who in a paper read before the second annual meeting of German oto-rhino-laryngologists, stated that in 32 out of 36 cases of ozæna they found diphtheria bacilli present, and in only five out of 30 cases of non-fœtid atrophic rhinitis. According to these investigators, the fœtor in ozæna apparently depended on the presence or absence of diphtheria bacilli; in other words, it was absent when the examination for diphtheria bacilli was negative. They also found that patients with ozæna had a relatively high antitoxin content in their blood as compared with patients suffering from atrophic rhinitis, and regarded this as a sign that the ozæna patient had had at some time an attack of diphtheria. On the other hand, Dr. Kawano, on examination of 65 cases of ozæna, found bacilli of the diphtheria group present in the nasal discharge only eight times, or in 12 per cent. Moreover, in not a single case were they true virulent or non-virulent diphtheria bacilli, but only pseudo-diphtheria bacilli. Even these pseudo-diphtheria bacilli were not absolutely identical with one another, but consisted of different representatives of the group, as was proved by experiments on animals and agglutination reactions. The supposed relationship of the fœtor of ozæna to pseudo-diphtheria bacilli was therefore open to doubt. The high antitoxin content of the blood in ozæna patients found by Beck and Brodt is regarded by Dr. Kawano merely as a coincidence. There are cases of ozæna with a low antitoxin content, as well as cases with a high antitoxin index, just as occurs in normal persons. There are, therefore, no grounds for supposing that ozæna patients must necessarily have had an attack of frank or latent diphtheria. Dr. Kawano also found that the changes produced by the action of diphtheria toxin on the mucous membrane of the nose and turbinate bones differed histologically from those caused in the rabbit's nose by the production of experimental ozæna, which bears a considerable resemblance to the lesions of human ozæna.

VACCINATION BY THE MOUTH.

THE idea of attempting to immunise animals by the buccal route is no new one. Pasteur essayed it in his experiments on anthrax in 1880, but the results obtained were not encouraging. In the interval various rather sporadic attempts at vaccination by this route have been forthcoming, but interest in the matter languished until stimulated again by Besredka's work on typhoidal infections, which we have already noticed in previous issues. A critical survey of the present position of the subject is given by Prof. A. Calmette in the October issue of the *Annales* of the Pasteur Institute, and is worthy of being consulted by all who are interested in this matter. After surveying the physiology of the intestine in reference to its microbic flora, he passes to a consideration of the different conditions in which oral vaccination has been claimed to be useful. These include infections so widely differing as the typhoids, dysenteries, cholera, Malta fever, tuberculosis, diphtheria, plague, and septic infections. The chief interest, however, centres around the use of oral vaccination in typhoid and dysentery. For the former the method has been tried in France in two human epidemics. In each of these cases the subsequent incidence of the disease in those who were vaccinated by the mouth compared very favourably with the incidence in those vaccinated in the ordinary way by the T.A.B. vaccine ; in neither case, however, were the conditions sufficiently well controlled to enable exact deductions to be made. The possibilities of this method of immunisation has perhaps even greater interest in connexion with bacillary dysentery, in which disease attempts to inoculate on the lines familiar in typhoid have notably failed, on account of the great toxicity of killed cultures of these organisms and the violent reactions which their injection provokes ; hence, if the oral route were found satisfactory it would be a very great gain indeed. Experiments on animals have been encouraging, and the human experiments of Nicolle and Conseil, which we have previously noted, are promising, but the method has yet to be tested on a large scale. Calmette concludes that the method is only, as yet, in the early days of its trial, and, especially with regard to the typhoidal diseases, he utters a warning against the possibility of the hurried abandonment of current methods whose efficiency has been proved, in favour of others, easier of application, but as yet of doubtful value.

INCUNABULA.

WHAT are incunabula ? The original meaning of the word is swaddling clothes, then it came to mean "origins" or the early stages of anything, and finally it was applied by the Germans with the particular meaning of early printed books. "Incunabula Medica: A Study of the Earliest Printed Medical Books, 1467–1480,"[1] takes its title from the presidential address delivered by Osler on the occasion of his election for the second time as President of the Bibliographical Society in 1914. The address as printed is not the address as delivered by Osler, but has been expanded by the addition of some bibliographical details obtained by Mr. Scholderer, assisted by Dr. Francis and Dr. Malloch. The book also contains a list of medical works printed before 1481, edited by Mr. Scholderer, two indices, the one of authors and books and the other of printers and places, together with 16 facsimile plates of pages from early printed books. There is a learned and charming preface from the pen of "A. W. P.," who, we imagine, must be Mr. A. W. Pollard, giving an account of Osler's connexion with the Bibliographical Society ; he served as President for seven years. Mr. Pollard is Keeper of the Printed Books in the British Museum and Hon. Secretary of the Bibliographical Society, and we gather from the preface that he is responsible for the shaping of Osler's address for printing. Issued under such auspices it is no wonder that the book as a whole is a real treasure for book-lovers, while the format, the printing, and the plates are worthy of the high standard of the Oxford University Press. Osler's address is the very man himself, learned, cultured, and written both as regards matter and manner in a way which would have delighted Richard of Bury, the famous book-loving Bishop of Durham. It deals with 67 medical writers, whereas Mr. Scholderer's list contains some 218 entries, although these, of course, are not all separate authors. Osler's conclusion is that "one cannot say that, for the first twenty-five years of its existence, printing did much, if anything, to free the profession from the shackles of mediævalism. Not until the revival of Greek studies did men get inspiration from the true masters of science."

Every medical man interested in medical history should read this book and every book-lover too, while as a cognate study we recommend a little book, not too well known, called the "Wanderings and Homes of Manuscripts," by that finished scholar and humanist, Dr. M. R. James, Provost of Eton. Books are not everything, but good books represent the ordered arrangement of the experience and mental output of many generations, and to use the words of the above-mentioned Richard of Bury in his allocution to books, they "are the wells of living waters, which father Abraham first digged, Isaac digged again, and which the Philistines strive to fill up."

THE PANDEMIC OF INFLUENZA IN INDIA IN 1918.

Dr. E. S. Phipson,[1] health officer of Simla, devotes his London M.D. thesis to the consideration of the pandemic of influenza in India, with special reference to the city of Bombay, of which he was recently the assistant health officer. After a review of past epidemics he describes the genesis of the 1918 outbreak. Apart from influenza the latter half of 1918 was unusually free from epidemic disease ; the incidence of plague was the mildest for 20 years, and the failure of the monsoon had caused a subnormal incidence of malaria. On the other hand, the stock of food was relatively low, the rainfall was subnormal. Prices were everywhere abnormally high, and the war had greatly depleted the medical staff, which at the best of times was inadequate for the enormous population. The first phase of the epidemic occurred in June and lasted barely four weeks, during which time the epidemic cost Bombay over sixteen hundred lives, at least a million working days, and an incalculable amount of discomfort, expense, and inconvenience. The second phase began after about an interval of two months on Sept. 10th, reached its height on Oct. 6th, and subsided in the second week of November. It differed from the first phase by the far greater frequency of complications. Broncho-pneumonia, which tended to assume a markedly toxæmic type, was responsible for the majority of deaths, and was as fatal to strong adults as to young children, and the old and debilitated. The mortality from influenza in Bombay City during the second phase, though very much less than that in India as a whole or in certain provinces such as the Central Provinces and Delhi, was 14,678, which was equivalent to 13·3 per 1000 of the estimated population or considerably more than three times the mortality occurring in the urban populations of England and Wales during the three epidemic waves of 1918–19. The combined mortality for all the hospitals in Bombay City was 34·21 per cent., but as only the worst cases and members of the poorest classes were admitted, this figure could not be regarded as an index of the case mortality in the general population ; 36·2 per cent. of the deaths occurred among persons aged 20 to 40, the highest mortality—61·6 per 1000 of the community—being among low caste Hindus and the lowest mortality—8·3 per 1000—among Europeans.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LI.—TREATMENT OF CHRONIC COLITIS.

A WRITER on chronic colitis is in the outset dismayed by the fundamental difficulty of definition. The term "colitis" can be employed when unequivocal evidence can be advanced of ulceration of the large bowel as in, inter alia, dysentery, tuberculosis, malignant disease, and infection by the *B. coli* and other pyogenic organisms in the condition known as ulcerative colitis. But most cases of what is generally known as chronic colitis cannot be attributed to any specific infection, whilst post-mortem evidence of any pathological condition of the bowel is lacking. To the last criticism one can only reply that the inflammation is of a catarrhal character.

Hypersecretion of Mucus.

In addition to the specific infections and malignant disease already mentioned, there are mechanical causes for irritation which alter the lumen of the bowel, such as ptoses, kinks, strictures, adhesions, and the pressure of external tumours which may lead to hypersecretion of mucus. To these must be added such irritants as scybala in chronic constipation, as well as the means adopted for relief, whether purgatives or ill-advised and unsuitable douches. Other familiar possibilities are intestinal parasites, subacute infections of the alimentary canal, and sepsis from teeth, nasal sinuses, tonsils, or pelvic viscera. Uric acid and other irritants which are excreted through the intestinal mucous membrane have similarly been blamed in this connexion,

When the well-recognised causes have been excluded there remain as a distinct group cases of primary colitis. To such a group a large variety of names has been appended, among which may be mentioned mucous colitis, muco-membranous colitis, mucous disease, intestinal neurosis, mucous colic, mucous croup, colitis pseudo-membranacea, membranous enteritis, myxoneurosis coli, myxorrhœa nervosa, tubular diarrhœa, muco-membranous colopathy. These names have clearly been coined either from a desire to indicate some ætiological belief or to emphasise some dominating symptom.

Symptoms.—Whatever disagreement exists as to the exact cause and nature of this condition there is fairly universal recognition of a symptom-complex. This includes a long history of constipation or of alternating constipation and diarrhœa; the passage of mucus in great or small quantity and in discrete jelly-like lumps or in the form of long membranous "casts"; the occurrence of abdominal pain; and the presence of a large variety of motor, sensory, and mental symptoms, some of which are attributed to auto-intoxication and most of which are conveniently, if unscientifically, lumped together as "neurasthenia." It is largely these symptoms which offer full scope for dissension, for the organicists maintain that they are the effect of some physical disability, whilst the supporters of a "neurosis," even admitting the possible influence of some infection or other physical cause, contend that it is the nervous system which is essentially at fault in responding with unreasonable vigour to a trivial stimulus. There is much to be said on both sides.

Routine Examination.

The first factor in treatment is a thorough investigation. This platitude may be true enough of any condition, but it receives special emphasis in this connexion, for nobody approaches the treatment of a case of chronic colitis without the hope that he may be dealing with a secondary colitis, the cause of which may be eradicated. The gratifying success which sometimes attends the removal of a chronically inflamed appendix with subsequent lavage through a cæcostomy or appendicostomy fistula is a tempting invitation to incriminate the appendix in many cases. But this diagnosis must be established as far as is possible by a careful survey of the symptoms; for unless the appendix is really the cause of the colitis its excision will not ameliorate the intestinal symptoms, and will in addition lower the general health on account of disappointment and of the psychic trauma which any laparotomy may produce.

Further, it should not be forgotten that a general examination may prevent the mortification of treating symptomatically some condition which demands a drastic reconstruction of one's ideas. Twice I have seen an example of rectal crises in which the dominating complaint was the passage of mucus with tenesmus, and three times a copious flow of mucus from the rectum through the pressure of a pelvic abscess; in all these cases "colitis" had been presumed. Above all, the sigmoidoscope should be employed as a routine; a local condition of the rectum or pelvic colon which must receive local treatment, or even a neoplasm may otherwise be overlooked.

Treatment of Mucous Colitis Proper.

1. *Dietetic Treatment.*—With one exception every dietetic régime has aimed at the inclusion of bland substances with little residue. Von Noorden, on the other hand, deliberately selected such articles as Graham bread and fruits with coarse skins and large seeds, with the idea of combating the constipation from which all these patients have long suffered. But by the time the patient comes for treatment she has already found that even the most drastic purgatives have lost their efficiency; the gut is in a spastic condition and any attempt to alleviate the constipation by irritating diet only aggravates it.

Selection of Diet.—According to the urgency of the case the following foodstuffs will be permitted in an ascending scale. Slightly mineralised non-effervescing waters—e.g., Evian, whey, vegetable soups, gruels, spaghetti or macaroni, milk puddings, purées of vegetables, fish and chicken, rusks, plain boiled meat or birds, purée of fruits. Combe's régime, in which a lacto-farinaceous diet predominates, is closely followed. Apart from its non-irritating character it will have some effect on the intestinal flora. In colitis the stools are usually alkaline; a diet low in protein tends to establish a milieu unfavourable to the growth of the anærobic (putrefactive) organisms.

2. *Treatment of the Bowels.*—Purgatives must be strictly prohibited with the sole exception of occasional small doses of castor oil. Psyllium seeds, agar, and liquid paraffin should be given even if, as is generally the case, they have all been utilised in the past and abandoned. In addition, olive oil injections are at once instituted. This treatment, if persisted in, is of the greatest value, both as offering a real cure for constipation and in improving the state of the colonic mucous membrane. After a little instruction these injections can be self-administered. From 8 to 10 oz. of washed olive oil warmed to 100° F. should be introduced into the rectum at a low pressure—a douche can being held or suspended only a foot above the level of the patient who lies in the knee-chest or left lateral position. The oil is retained all night, a sanitary towel being worn to prevent leakage; in the morning the bowels should be comfortably emptied. These injections must be continued nightly for at least a fortnight, and are then gradually reduced, as the bowels are found to act without assistance, until eventually only an occasional injection is required.

Whilst I emphasise the very great value of oil enemata, other methods of intestinal lavage may be admitted if skilfully performed and if the fluid employed is unirritating. The waters of Plombières and Chatel Guyon (among others) are unexceptionable, but strong sulphur waters should be rigidly forbidden. Rarely astringents may be necessary, in which case tannigen or tannalbin will be found most suitable.

3. *Relief of Pain and Flatulence.*—Belladonna is invaluable; probably all sufferers from mucous colitis are vagotonic. This drug may usefully be employed in pill form with menthol and valerian—

e.g., ext. belladonn. gr. $\frac{1}{4}$, menthol gr. $\frac{1}{2}$, ext. valerian gr. $1\frac{1}{2}$, pulv. valerian gr. i. Hot applications—e.g., compresses of flannel wrung out in hot water—will always prove comforting.

4. *Reduction of Putrefaction.*—Mention has been made of the influence of food in this connexion. Of intestinal disinfectants I cannot speak with any confidence. Lactic acid, however, is often valuable, but as patients with colitis cannot tolerate milk, a pure culture is preferable to a soured milk. Vaccine therapy is rarely admissible, based as it is on so complicated a bacteriology as that of the intestinal tract.

5. *General Treatment.*—When spa treatment leads to good results it is not easy to apportion the credit due to the climate, the routine discipline, and the suggestive effect. Yet climate is certainly of some importance. I have had the humiliation of experiencing failure after reproducing faithfully and in every detail a treatment which had been remarkably successful in Lausanne. Patients with colitis are very intolerant of cold, and advice to be warmly clad in flannel and to wear an abdominal binder should be insistent. The benefit of a few weeks in bed is explained not only by the rest but by the constant warmth. Enteroptosis is generally present, but as usual it is difficult to estimate the extent of its effect. It is certainly a contributory factor to constipation, and benefit from treatment by a suitable abdominal support is unquestionable. Whether anæmia is present or not it is well to give a course of intramuscular injections of cacodylate of iron, sodium glycerophosphate, and strychnine. Exercise must be graduated according to the inclination and physical capacity of the subject, but only open-air exercise should be encouraged. Massage, especially of the abdomen, may be of value but should be stopped if pain is produced. Galvanism has often a sedative effect on the intestinal spasm and the abdominal nervous system in general.

6. *Surgical Treatment.*—Were one satisfied, first of all that the colon itself was diseased, and secondly that it is in any case rather a superfluous organ, one might be more encouraged to consider ileosigmoidostomy or more formidable surgical procedure, of which I have had no personal experience.

7. *Treatment of the Nervous System.*—This is too vast a subject for consideration here. Unfortunately, the majority of patients develop a mental outlook which, if it has not reconciled them to a life of complete invalidism, has at least prepared them to make the worst of a bad job. So they tend to persist in a mode of living which is only too likely to perpetuate the disability—want of exercise, of fresh air, of interests and of occupation. The disappointment of previous failures and the lack of confidence engendered by the contemplation of contradictory views as to the ætiology of their condition do not contribute to an enthusiastic coöperation in what must necessarily be a prolonged undertaking. Inasmuch as the psychical handling of a patient means individual study, it would be tedious to indulge in generalities. But one thing may be mentioned. Although a conscientious adherence to details must be secured, too many sufferers have had their attention so intimately drawn to their excreta as to become monomaniacal. Let the patient understand from the outset that the task of examination must be left to others.

8. *Treatment of Acute Attacks.*—Occasionally the accumulation of large quantities of inspissated mucus leads to an attack of very severe abdominal pain for which absolute rest in bed is imperative. Moist warmth is applied to the abdomen. The diet is reduced to plain Evian water and water-gruel made with crème d'orge, arrowroot, or rice for two days. An injection of morphia and atropine is given for relief of the enterospasm. A large, warm, olive oil enema immediately followed by a pint of warm water is slowly administered. Two hours later evacuation of the mucus will be completed by the injection of two pints of water at 99° F. containing half a drachm of pure oleate of soda.

(FROM AN OCCASIONAL CORRESPONDENT.)

CONFERENCE OF OHIO HEALTH COMMISSIONERS.

THE State of Ohio comprises a rural population of six millions, divided amongst 88 counties. The public health organisation of this community is very young, as may be judged from the fact that the annual conference of health commissioners held from Nov. 19th to 24th was only the fourth in its history. Ideally each county and each town of 5000 inhabitants or more should be in the special jurisdiction of a health commissioner. Actually there are 42 county commissioners and 26 city commissioners employed as full time public servants, while a large number of doctors in addition give a part of their time to public health work. The health laws of the State provide that all these men shall attend the annual conference at the public expense, and there was, therefore, a good audience gathered at Columbus to hear the distinguished speakers who had been invited to read papers. These included Surgeon-General H. S. Cumming, of the United States Public Health Service; Profs. A. W. Freeman and W. H. Frost, ot the Johns Hopkins School of Public Health; Dr. Haven Emerson, professor of public health at Columbia University; Dr. E. R. Hayhurst, professor of preventive medicine at the Ohio State University; Dr. Luisly Williams, and Dr. W. H. Park, as well as other speakers of international fame.

Coöperation of General Practitioner and Health Commissioner.

The most significant lesson of this conference, and one that any European observer could not have failed to remark, was the extent to which the whole medical profession of the State is mobilising itself behind the projective measures of preventive medicine. The president of the State Medical Association was present and pledged the unlimited support of his organisation. The Columbus Academy of Medicine entertained the commissioners at their own house with many cordial and fraternal expressions of goodwill. Moreover, it was clear that the two large campaign measures which have been planned for the coming year will stand or fall by the loyalty with which the profession as a whole supports them. This is clearly an integral part of the policy of the State Director of Health, Dr. John E. Monger, himself a practising physician, determined, so he says, to return to that calling, and one of the methods by which he appears to have succeeded in convincing the doctors of this State that social medicine is not necessarily medicine that has been socialised.

The Cure and Prevention of Diphtheria.

The provision of free antitoxin to all cases of diphtheria is a legal obligation of each health commissioner. Until recently the price of serum had been a good deal higher than just profits for the manufacturer need have dictated. The State Department of Health had arranged to purchase on a large scale at a reasonable rate and the main subject to be discussed was the method of distribution. In the larger cities, as for example in Cleveland, the serum is kept in ice-chests at every police-station. In the country it has sometimes been distributed through the pharmacists and sometimes given to the private practitioner, who must account for its use (thus providing a useful check on the reporting of suspected cases). Both these methods are open to the objection that the serum is frequently not preserved in an ice-chest. A better method seemed to be to keep the whole stock in the office of the Health Commissioner, where it may always be reached in a few hours.

The discussion on the prevention of diphtheria was ushered in by an interesting paper from Dr. W. H. Park, president of the American Public Health

Association and director of the New York City Health Department Laboratories. Dr. Park described the use of the Schick test and toxin-antitoxin immunisation in New York. There it is hoped to immunise this year about 100,000 school-children and some 20,000 children of pre-school age. The response of the public after four years of educational and prophylactic work is distinctly more cordial. The whole work has been carried on by eight doctors, eight nurses, and eight assistants, and the results are shown in the following table, which was obtained from Dr. Park.

Year.	Total cases.	Total deaths.	Deaths per 100,000 population.
1919	14,000	1239	22
1920	14,100	1045	21
1921	15,000	891	16
1922	10,000	876	15

In 1923, if the rates continue for the last six weeks as for the first 46 weeks, there will be about 8000 cases with some 550 deaths, or a rate of less than 10 per 100,000. Dr. Park suggested that the increased incidence during the first two years of the campaign might be due to improvement in reporting cases as a result of the extra attention to the subject of diphtheria. It will be seen that the death-rate has been cut in half, although not more than one-third of the children have been immunised, and no compulsion whatever has been exercised. The Ohio Department of Health has adopted as its slogan, "No child in Ohio need die of diphtheria." Actually some 1000 die yearly from this disease. With 169 health commissioners at work, strongly backed by the whole medical profession and armed with toxin-antitoxin to be supplied by the State, we should see a reduction in mortality even more rapid and more striking than that in New York.

Regular Physical Examinations.

The movement for a "nation-wide health examination campaign" has been sponsored by the National Health Council for some years now. The American Medical Association has also warmly endorsed this movement, as I have indicated in a previous letter. Dr. Haven Emerson, the chairman of the committee of the A.M.A. Council on Health and Public Instruction, introduced the subject with a paper in which he divided the public health movement into three eras: the era of police and quarantine from 1700 to 1900; that of the voluntary health organisations, beginning with the present century; and the present era of health examinations and popular health instruction, which brings the whole public into active endeavour towards the suppression of disease. He showed how all modern health movements, infant hygiene, school hygiene, anti-tuberculosis, &c., are all dependent upon frequent contact between the individual and his physician. The result may be typified by the tuberculosis work in New York clinics. Whereas formerly it was rare to see a new patient who was not in an advanced stage of the disease, last year 70 per cent. of the patients coming to 31 tuberculosis clinics in that city were not tuberculous at all. It is now the rare exception to see a case for the first time at an advanced stage. He suggested that the physician should examine apparently healthy individuals not less often than laid down below.

In the pre-natal period..	4 times.
,, first 2 years	20 ,,
From 2–5 years old	Every 6 months.
,, 6–15 ,, ,, ...	Once a year.
,, 16–25 ,, ,, ...	Once in 2 years.
,, 25–60 ,, ,, ...	Once a year.

The public needs to develop a conscience in this matter. At present many people who would be chagrined if their roof were to leak and make a spot on the dining-room ceiling are not at all ashamed if their child's heart leaks. The professional organisations cannot advertise themselves, the need for regular examination must be taught by the voluntary associations and by health officers, but the profession needs to equip itself for this kind of work, for which it has been inadequately trained, and in which it has too little experience.

After a discussion, in which several speakers representing the medical association supported the movement and emphasised the importance of thoroughness and care in making the examinations, Dr. Hayhurst announced the plans that have been made for launching this campaign in Ohio.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

GRANTS TO HOSPITALS AND CONVALESCENT HOMES.

A meeting of the President and General Council of King Edward's Hospital Fund, for the purpose of awarding grants to the hospitals and convalescent homes for the present year, was held on Dec. 18th, the Prince of Wales being in the chair.

Lord Revelstoke (hon. treasurer) in reporting the amount received for general purposes by the Fund to Dec. 3rd, said that this time last year he had expressed the hope that the income to be derived from the munificent legacies of Lord Mountstephen and Sir Thomas Sutherland would form the nucleus of a permanent increase in the distribution. The Fund had already received a large part of this increased income. The total income from all investments had reached £145,000 this year, as against £114,000 in 1922. On the other hand, ordinary legacies had decreased, although for the past 12 months they still reached the substantial figure of £47,000. The net result was that the Fund was able to distribute £235,000, or £15,000 more than the amount distributed a year ago. The ordinary income from subscriptions and donations had been well maintained, owing largely to an anonymous donation of £6,500 received in May. The estimates also included the amount which the Fund hoped to receive from its largest contributor, the League of Mercy. There was every hope that the sum of £235,000 would be provided very nearly, if not quite out of the current income of the year.

Sir William Collins, in making the annual statement on behalf of the League of Mercy, said that so far as they could tell from the subscriptions at present received, a sum of £14,000 would be handed over to the King's Fund before the end of the year. This would make a total sum of £353,000 handed over to the Fund since the foundation of the League. Adding the grants made to hospitals outside London, the total came to £407,682.

The Chairman of the Hospital Economy Committee (Mr. Leonard L. Cohen) presented the report of the Committee on

Recovery Branches of London Hospitals,

the general conclusions of which were: that, in view of the advantages to the patients, the development of recovery branches deserved encouragement, subject to the proviso that before a branch is established those responsible for its finance should realise that the apparent cheapness resulting from the low cost per bed at the branch was largely illusory; that its establishment was a form of hospital extension and must be budgeted for as such; and that no form of extension should be undertaken without particularly careful consideration both by the hospital and by the King's Fund, until the restoration of voluntary hospital finance had been completed.

Dr. H. Morley Fletcher seconded the adoption of this report, and the motion was carried unanimously

The Chairman of the Distribution Committee (Sir Cooper Perry) presented the report of the Committee on the

Distribution to Hospitals

(including recovery and convalescent branches). This stated that a new principle had been adopted this year in drawing the distinction between the distribution to hospitals and the distribution to convalescent homes. The grants to convalescent or recovery institutions attached to particular hospitals of London were now included with the grants to the parent hospitals, and the separate distribution to convalescent homes was confined to institutions which were not branches of a hospital. The new procedure had arisen out of an inquiry by the Hospital Economy Committee into the relation between hospitals, homes of recovery, and convalescent homes. Lord Cave's Committee had suggested that the provision of auxiliary hospitals on the outskirts of cities for cases no longer requiring constant medical or surgical supervision might prove an economical method of increasing hospital accommodation, and the hospitals which had already established recovery branches were anxious that the King's Fund should recognise the difference between these branches and ordinary convalescent homes. In determining the amount of the combined grant regard to the extent to which the work at the branch approximated to hospital work on the one hand, or to purely convalescent work on the other hand, had been taken into consideration. The amount placed at the disposal of the Distribution Committee for allocation amongst hospitals and their recovery and convalescent branches at the present distribution was £233,000. The amount distributed last year at the ordinary distribution was £215,000 to hospitals and £3385 in separate grants to recovery and convalescent branches. In June last the King's Fund made a final distribution of £115,000 out of the proceeds of the Hospitals of London Combined Appeal, £150,000 having already been distributed in August, 1922, and £100,000 in October, 1922. The Distribution Committee's report on the whole of this special distribution of £365,000 had been published in the annual report of the King's Fund for 1922. A sum of £5000 which had since been received from the Combined Appeal was included in the present ordinary distribution. The number of hospitals applying for grants out of the ordinary distribution was 116, as against 112 in 1922. The need of maintenance grants continued to be the first consideration, and the Distribution Committee had therefore again limited the grants in aid of schemes of capital expenditure to cases where the work was particularly urgent and was within a reasonable distance of being carried out. The total amount of such grants recommended this year was £30,100, as against £26,500 in 1922. The total grants to maintenance out of the ordinary distribution amounted to £202,900, as against £188,500 in 1922 to hospitals, and £3385 to their branches.

Several of the schemes to which the Fund had made grants in the past were still deferred owing to financial difficulties, and the Distribution Committee recommended that the following grants should be renewed: City of London Hospital for Diseases of the Heart and Lungs, £1000 to improvements; East Ham Hospital, £500 to rebuilding; French Hospital, £100 to improvements; General Lying-in Hospital, £4000 to rebuilding; Hornsey Cottage Hospital, £500 to extension; London Lock Hospital, £3500 balance of grants to reconstruction of the Harrow-road Hospital; Queen Charlotte's Lying-in Hospital, £3100 to new out-patient department and other improvements; Royal National Orthopædic Hospital, £1000 to extension of out-patient department; St. Monica's Hospital, £60 to improvements; St. Thomas's Hospital, £3750 to extension of nurses' dining-room, and £1000 to improvements.

*List of Awards.**

Lord Somerleyton (hon. secretary) presented the list of awards as follows:—

	£
Acton Hospital (of which £500 to deficit on extension, in accordance with the scheme submitted to the Fund) ..	700
All Saints' Hospital	100
Baby Clinic Hospital (Kensington)	25
Beckenham Cottage Hospital (of which £1000 to extension, in accordance with the scheme submitted to the Fund)	1,200
Belgrave Hospital for Children	1,200
Blackheath and Charlton Hospital	150
Bolingbroke Hospital (of which £1000 to erection of new ward block, in accordance with the scheme submitted to the Fund)	2,000
British Hospital for Mothers and Babies, Woolwich (of which £500 towards the building of the amalgamated hospital, in accordance with the scheme submitted to the Fund)	1,000
Central London Ophthalmic Hospital	600
Central London Throat and Ear Hospital (of which £200 to provision of X ray equipment, in accordance with the scheme submitted to the Fund)	300
Charing Cross Hospital	4,500
Chelsea Hospital for Women (including Convalescent Home at St. Leonards) (of which £1000 to new nurses' home, in accordance with the scheme submitted to the Fund)	1,850
Cheyne Hospital for Children	200
City of London Hospital for Diseases of the Heart and Lungs (Victoria Park) (including Convalescent Home at Saunderton)	3,550
City of London Maternity Hospital	1,000
Clapham Maternity Hospital	300
Dreadnought Hospital (Seamen's) (including Sanatorium at Liphook, and Convalescent Home at Cudham) ..	3,550
East End Mothers Lying-in Home	600
East Ham Hospital	100
East London Hospital for Children (including Convalescent Home at Bognor)	3,200
Elizabeth Garrett Anderson Hospital (including Recovery Branch at Barnet)	1,650
Eltham and Mottingham Cottage Hospital	25
Evelina Hospital (of which £250 to reduce debt) ..	1,250
Finchley Memorial Hospital (of which £250 to scheme)	550
Florence Nightingale Hospital for Gentlewomen (of which £100 to reduce debt)	350
French Hospital	300
General Lying-in Hospital (of which £50 to improvements)	650
German Hospital	300
Grosvenor Hospital for Women	550
Guy's Hospital (of which £1000 to provision of central power station)	11,500
Hampstead General and North-West London Hospital (of which £500 to reduce debt)	3,000
Hendon Cottage Hospital (of which £250 to extension of ward block, in accordance with scheme to be approved by the Fund)	500
Hornsey Cottage Hospital (of which £500 to extension, in accordance with the scheme submitted to the Fund)	650
Hospital for Consumption, Brompton (including Sanatorium at Frimley)	1,250
Hospital for Diseases of the Throat (of which £1000 to reconstruction, in accordance with the scheme submitted to the Fund)	1,200
Hospital for Epilepsy and Paralysis (of which £1000 to extension of out-patient department, in accordance with the scheme submitted to the Fund)	2,750
Hospital for Sick Children	5,000
Hospital for Women (Soho-square)	1,000
Hospital of St. John and St. Elizabeth	750
Infants Hospital (of which £100 to reduce debt and £200 to remodelling of basement)	800
Invalid and Crippled Children's Society Hospital (Canning Town)	400
Italian Hospital	300
Jewish Maternity Home	25
Kensington, Fulham, and Chelsea General Hospital ..	25
Kensington Dispensary and Children's Hospital ..	25
King Edward Memorial Hospital (Ealing)	600
King's College Hospital (of which £500 to improvements)	8,000
London Fever Hospital	350
London Homœopathic Hospital (including Convalescent Home at Eastbourne) (of which £250 to reduce debt)	1,800
London Hospital (including Recovery Branch at Reigate)	14,650
London Lock Hospital (to maintenance of Harrow-road Hospital)	600
London Temperance Hospital (of which £1000 to new nurses' home, in accordance with the scheme submitted to the Fund)	3,000
Maternity Charity and District Nurses' Home, Plaistow	200
Medical Mission of the Good Shepherd Babies' Home (Hoxton)	25
Metropolitan Ear, Nose and Throat Hospital	25
Metropolitan Hospital	3,500
Middlesex Hospital (including Convalescent Home at Clacton)	7,500
Middlesex Hospital Cancer Charity	900
Mildmay Memorial Hospital	400
Mildmay Mission Hospital	1,000
Miller General Hospital for South East London (including Convalescent Home at Bexhill)	3,600
Mothers' Hospital of the Salvation Army	325
Mount Vernon Hospital (Fitzroy-square and Northwood)	1,000
National Hospital for Diseases of the Heart	350
National Hospital for the Paralysed and Epileptic (including Convalescent Home at Finchley)	3,700
Nelson Hospital (South Wimbledon) (of which £500 to deficit on extension, in accordance with the scheme submitted to the Fund)	1,000
Northcourt Hospital and Home for Sick Children (Hampstead) (in consideration of the fact that curable cases are admitted)	50

---

* The Distribution Committee draw attention to the fact that it must not be assumed that the reduction or absence of a grant implies dissatisfaction.

	£
North Islington Infant Welfare Wards	25
Norwood and District Cottage Hospital	450
Paddington Green Children's Hospital (including Convalescent Home at Slough)	850
Passmore Edwards Hospital for Wood Green, &c.	50
Poplar Hospital for Accidents (including Convalescent Home at Walton-on-the-Naze) (of which £500 to new nurses' home, in accordance with the scheme submitted to the Fund)	650
Prince of Wales's General Hospital (including Convalescent Home at Nazeing) (of which £2000 to reduce debt, and £1,000 to extension, in accordance with the scheme submitted to the Fund)	6,050
Queen Charlotte's Lying-in Hospital (including Convalescent Home at Kilburn (of which £250 to reduce debt)	1,550
Queen Mary's Hospital for the East End (including Convalescent Home at Theydon Bois) (of which £2000 to new out-patient department)	5,700
Queen's Hospital for Children (including Convalescent Home at Bexhill) (of which £750 to debt and £250 to additional nurses' accommodation, in accordance with scheme to be approved by the Fund)	4,750
Royal Dental Hospital of London	250
Royal Eye Hospital	750
Royal Free Hospital (of which £1,000 to new nurses' home, in accordance with the scheme submitted to the Fund)	6,000
Royal Hospital, Richmond	650
Royal London Ophthalmic Hospital	3,000
Royal National Orthopædic Hospital (including Country Branch at Stanmore) (of which £1,000 to extension of country branch, in accordance with scheme to be approved by the Fund)	4,500
Royal Northern Hospital (including Royal Chest Branch in City-road, Recovery Branch at Southgate, and Convalescent Home at Clacton) (of which £1000 to new nurses' home, in accordance with the scheme submitted to the Fund)	9,000
Royal Waterloo Hospital for Children and Women (including Convalescent Home at Whippingham)	2,575
Royal Westminster Ophthalmic Hospital	700
St. Andrew's Hospital (Dollis Hill)	150
St. Bartholomew's Hospital (of which £1000 to new operating theatres, in accordance with the scheme submitted to the Fund)	10,000
St. Columba's Hospital	350
St. George's Hospital (including Recovery and Convalescent Branch at Wimbledon) (of which £500 to extension of out-patient department)	6,900
St. John's Hospital, Lewisham	600
St. John's Hospital for Diseases of the Skin (of which £50 to furnishing of nurses' home)	350
St. Luke's Hospital for Advanced Cases (of which £500 to acquisition of new premises, and their adaptation in accordance with the scheme submitted to the Fund)	700
St. Mark's Hospital	400
St. Mary's Hospital (of which £250 to electric lifts)	6,000
St. Mary's Hospital for Women and Children, Plaistow (of which £500 to deficit on new nurses' home, in accordance with the scheme submitted to the Fund)	2,000
St. Monica's Home Hospital	100
St. Peter's Hospital for Stone (of which £100 to reduce debt)	350
St. Saviour's Hospital for Ladies of Limited Means (Osnaburgh-street)	100
St. Thomas's Hospital (of which £1000 to reduce debt)	9,500
Samaritan Free Hospital for Women (including Convalescent Home at Amersham)	1,325
Santa Claus Home	50
South-Eastern Hospital for Children (Sydenham) (of which £750 to deficit on new out-patient department, in accordance with the scheme submitted to the Fund)	1,500
South London Hospital for Women	1,250
Stoke Newington Home Hospital for Women (of which £100 to new operating theatre)	150
Streatham Babies' Hospital	25
University College Hospital	7,000
Victoria Hospital for Children (including Convalescent Home at Broadstairs) (of which £750 to deficit on new physio-therapeutic department and nurses' accommodation, in accordance with the scheme submitted to the Fund)	2,950
Walthamstow, Wanstead, and Leyton Children's and General Hospital	600
West End Hospital for Nervous Diseases (of which £500 to improvements, in accordance with the scheme submitted to the Fund)	2,000
Western Ophthalmic Hospital	250
West London Hospital (of which £500 to reduce debt)	5,000
Westminster Hospital (of which £5,000 to improvement of existing hospital, in accordance with the scheme submitted to the Fund)	7,500
Willesden General Hospital (of which £1000 to extension as general hospital, in accordance with the scheme submitted to the Fund)	2,500
Wimbledon Hospital (of which £500 to deficit on new nurses' home, in accordance with the scheme submitted to the Fund)	850
Winifred House Invalid Children's Convalescent Hospital Home	25
Woolwich and Plumstead Cottage Hospital (see special grant below)	25
Total	£231,500

Special Grant.—Woolwich and District War Memorial Hospital Building Fund (to provision of general hospital, in accordance with the scheme submitted to the King's Fund), £1,500.

Sir John Bland-Sutton seconded the motion, which was put and carried unanimously.

The chairman of the Distribution Committee, Sir Cooper Perry, than presented the report of the committee on the

Distribution to Convalescent Homes

not attached to particular hospitals in London, which stated that the sum available for distribution was £2000; the amount distributed to such convalescent homes in 1922 was £1615; grants to the recovery and convalescent branches of hospitals (which amounted to £3385 in 1922), it was pointed out, are now combined with the grants to the parent hospitals. The number of applications eligible for consideration amounted to 40, as against 41 last year.

List of Awards.

Major Harold Wernher (hon. secretary) presented the list of awards to convalescent homes not attached to particular hospitals as follows:—

	£
All Saints' Convalescent Home, Eastbourne	200
All Saints' Convalescent Home, St. Leonards	50
Baldwin Brown Convalescent Home, Herne Bay	25
Beau Site Convalescent Home, Hastings	25
Brentwood Convalescent Home for London Children, Brentwood	25
Brooklands Home (Invalid Children's Aid Association), Worthing	75
Bushey and Bushey Heath Children's Convalescent Home, Bushey	25
Children's Convalescent Home, Beaconsfield	25
Children's Cottage Hospital (in consideration of convalescent cases), Cold Ash, Newbury	25
Children's Home Hospital, Barnet	25
Clevedon Sanatorium (Invalid Children's Aid Association), Broadstairs	50
Convalescent Home for Poor Children, St. Leonards	100
Convalescent Police Seaside Home, Hove	100
Edgar Lee Home (Invalid Children's Aid Association), Willesden	50
Florence Emma Home (Invalid Children's Aid Association), Dover	25
Friendly Societies' Convalescent Homes, Dover and Herne Bay	25
Hamilton House (Invalid Children's Aid Association), Seaford	50
Highgate Convalescent Home for Children, Highgate	50
Home for Invalid Children, Brighton	25
London and Ascot Priory Convalescent Home, Bracknell	100
London and Brighton Female Convalescent Home, Brighton	25
Mental After-Care Association Homes, Fairlight	150
Metropolitan Convalescent Institution, Bexhill, Broadstairs (Children) and Walton	100
National Sunday School Union, Bournemouth	25
St. Andrew's Convalescent Home, Folkestone	75
St. Andrew's Convalescent Hospital, Clewer	25
St. John's Home, Kemp Town (Brighton)	50
St. Luke's Home (Children) (in consideration of convalescent cases), Woodley (Reading)	25
St. Mary's Convalescent Home, Birchington	25
St. Mary's Home for Children (in consideration of convalescent cases), Broadstairs	50
St. Michael's Convalescent Home, Westgate	50
St. Nicholas' Home (Church of England Waifs and Strays), Pyrford	50
Seaside Convalescent Hospital, Seaford	100
Suffolk Convalescent Home, Felixstowe	50
Surgical Home for Boys (in consideration of convalescent cases), Banstead	25
Thomas Turner Convalescent Home for Children (Church of England Waifs and Strays), Broadstairs	50
Tilford Convalescent Home for Children, Farnham	25
Victoria Home for Invalid Children (in consideration of convalescent cases), Margate	25
Total	£2000

Prof. Winifred Cullis seconded the motion which was put and carried unanimously.

The Chairman of the Ambulance Cases Disposal Committee (Sir William Collins), in making a statement on the present position of the inquiry, said that the committee had now completed the oral evidence; the draft report was almost ready for consideration. He hoped the report would be presented to His Royal Highness before the new year was far advanced.

The Prince of Wales then read the following message from the King: "I am highly gratified that the Fund is this year enabled to increase its distribution from £220,000 to £235,000; also that the difficulties facing the voluntary hospital system are being steadily overcome by the methods adopted and advocated by the Fund. I sincerely trust that continued success will attend the work of the council and committees."

Remarks by the Prince of Wales.

Continuing, the Prince of Wales said that the King's Fund was taking another stride forward. The distribution was being increased by £15,000. For the last two years it had been £220,000; this year it was £235,000. Nearly the whole of this was provided from income received during the year, in spite of the fact that legacies were considerably less than in 1922. The increase in income, which had more than balanced the fall in legacies, was chiefly due to the dividends from the bequests of Lord Mountstephen and Sir Thomas Sutherland. But the Fund had also been greatly helped by an anonymous donation of £6500. The novel feature in the report of the Distribution Committee was the new method of dealing with the recovery and convalescent branches of hospitals. The question of recovery branches came up for decision this year because of the inquiry by the Hospital Economy Committee, and the report was an example of the way in which the King's Fund, as Voluntary Hospitals Committee for London, was steadily working through that admirable text-book on Voluntary Hospital Finance, the report of Lord Cave's Committee.

On matters that did not directly affect the Distribution Committee, the other committees would report to the council at the annual meeting in the spring. But there has been an interesting development of the work of the Revenue Committee. Two subcommittees have been appointed. One, under the chairmanship of Lord Burnham, was to assist, partly by general propaganda in aid of the work of the King's Fund and the hospitals; partly by enlisting the help of members of the professions of science, art, literature, law, &c.; and partly, by continuing from time to time some of the activities of the educational auxiliary which did such good work for the Combined Appeal. The other, under Major Wernher, was to assist both the King's Fund and the hospitals to increase their revenue in any other ways not already covered by some existing agency. Besides a nucleus drawn from the Revenue Committee, Lord Burnham's Committee, so far, contained the following members, most of whom were not otherwise officially connected with the King's Fund, but who have shown, through the Combined Appeal or in other ways, their desire to give personal assistance in connexion with their respective professions: Art, Prof. W. Rothenstein; drama, Mr. Dennis Eadie; education, Sir William Beveridge and Dr. Ernest Barker (University of London); Mr. George Smith and Miss M. D. Brock (secondary schools); Mr. J. W. Samuel and Miss C. M. A. Coombs (elementary schools); law, Sir Reginald Acland, K.C.; literature, Mr. W. Pett Ridge and Mr. C. David Stelling; music, Mr. A. J. Hadrill; science, Prof. W. T. Gordon.

On the side of definite propaganda a leaflet, with a foreword by Mr. Pett Ridge, answering questions about the present financial position of the hospitals of London, had already been issued. One of the general objects of propaganda was to bring the hospitals before people, not only or even chiefly as institutions appealing for subscriptions, but as a very important factor in our social organisation, doing essential work both for the sick poor and for the health of the whole community, and to inculcate in the mind of the public generally a greater sense of responsibility for the regular and systematic support of the hospitals on these grounds. The object was to assist the hospitals and the other central agencies, not to compete with them. The central agencies now included the new Hospital Saving Association for organised contributions from employers and employees. Another new piece of work, undertaken at the request of the Voluntary Hospitals Commission, was an inquiry by a Special Committee, with Sir William Collins as chairman, into the question of hospital accommodation for accident cases.

The Prince of Wales, having briefly acknowledged a vote of thanks, the proceedings terminated.

ANNUAL MEETING OF PRESIDENTS OF THE LEAGUE OF MERCY.

On Dec. 19th the Prince of Wales, as Grand President of the League of Mercy, presided over the annual meeting of presidents of the League at St. James's Palace, when he read the following message from the King: "The Queen and I desire to convey to the presidents, vice-presidents, members, and officers of the League of Mercy our warm appreciation of their sustained interest in this great and successful movement. More than a quarter of a century ago, King Edward, himself a firm believer in the voluntary system, instituted the Fund that bears his name, and, two years later, the League of Mercy; and, though during this period many changes have taken place in the hospital world, I feel that this system still commands the confidence and sympathy of all classes."

Continuing, the Prince of Wales said that looking at the statistics of 113 London hospitals it would appear that in the year 1922 the only source of ordinary revenue which showed a marked increase was that of payments made by patients, amounting to £490,000, or £70,000 more than in 1921. Such payments, together with various rival contributory or provident schemes offering prospective advantages, were not without influence on such a central collecting agency dependent on disinterested personal service as the League of Mercy. It was, however, gratifying to learn, on the authority of the Voluntary Hospitals Commission, in their report upon contributory schemes, that most hospitals rely upon the charitable instinct of the public, and maintain the principle that the necessitous poor and the medically urgent must have the first call upon the resources of the hospital. Other rival schemes, such as ballots and similar competitions, contrived to raise funds for charities, had become popular, and had elicited a warning from the London County Council that, in the case of some of them, a considerable percentage of their contributions, which are ostensibly given for charity, finds its way into the pocket of the professional organiser. No such charge could be levelled against the League of Mercy, since all contributions received by its members and paid in through the vice-presidents and presidents went, without any deductions whatsoever, to the maintenance of the voluntary hospitals. He had received the gratifying intimation that the British Charities Association had decided to entrust to the League of Mercy for distribution by it the sum of £1000 in advance derived from their hospitals competition.

Sir Frederick Green, the hon. treasurer, in his report said that the total of the collections this year was in the neighbourhood of £20,500, about £800 less than in the previous year. They hoped to be able to give £14,000 or £15,000 to King Edward's Fund for division among hospitals, and about £5000 to extra-metropolitan hospitals.

TUBERCULOSIS.

The Tuberculosis Campaign in Lancashire.

THE annual reports of the central tuberculosis officer for Lancashire have in the past been animated by a spirit of organised hustle, and the last report, which is for the year 1922, is no exception to this rule. This is the more creditable as there is at present a tendency to lapse from that spirit of constructive reform which was such a driving force at the end of the late war. Rationing of expenditure has been imposed in Lancashire as elsewhere, but owing to economies and fall in prices, the tuberculosis service has been extended and improved in several respects. The institutional accommodation has been increased from 678 beds at the end of 1922 to 772 in October, 1923. A recent survey of the incidence of tuberculosis in Lancashire has brought out striking differences in the distribution and mortality of pulmonary tuberculosis in various parts of the county, and this investigation, like a similar investigation recently carried out in Denmark, has emphasised the gregarious character of this disease. In 1922 there were 1626 "contacts" examined in their homes or at dispensaries, and in 79 cases definite tuberculosis was discovered. This ratio of 4·86 per cent. is much higher than any random sampling of the ordinary population would produce, and again we see the gregarious element of the disease demonstrated. An eloquent testimony to the tact and efficiency of the Lancashire tuberculosis officers is the improvement in early notification. In 1918, in as great a proportion as 18 per cent. of the deaths from tuberculosis, the disease had not been notified before death. In 1922 this was the case in only 8 per cent., the period 1918–22 showing a steady improvement in this respect. Omissions and delays in notification may, to a certain extent, vary in frequency in different localities with the efficiency of the tuberculosis staff, and the fact that in Lancashire only 8 per cent. of the tuberculosis deaths occurred before notification is a convincing proof of the smooth coöperation of the tuberculosis staff with the general practitioners in the county. Out of 4059 new cases ("contacts" excluded) examined in 1922 by the tuberculosis officers, 3116, or 76·7 per cent., had been referred to the dispensaries by general practitioners and other medical officers. In 1921 this ratio was only 68·9 per cent. A study of the results of sanatorium treatment and a comparison of it with domiciliary treatment shows very clearly that the prognosis is far better for the former. Thus, of 981 sanatorium cases and 728 non-sanatorium cases in the early and intermediate stages and sputum-negative, commencing treatment in the period 1914–18, it was found that only 16 per cent. of the sanatorium patients and 42·6 per cent. of the non-sanatorium patients had died by the end of 1922.

The Ultimate Results of Nephrectomy for Renal Tuberculosis.

In the *Schweizerische medizinische Wochenschrift* for Nov. 29th Prof. F. Suter, of Basel, has published the results of inquiries made in the winter of 1920–21 as to the fate of 204 patients who had undergone nephrectomy for renal tuberculosis between 1896 and 1920. Only seven of these patients could not be traced. In 20 per cent. tubercle bacilli could not be found in the urine, and in at least 70 per cent. of the male patients the genital system was also tuberculous. Only in a few cases was nephrectomy in bilateral disease attempted, but there were several in which the non-tuberculous kidney was at last temporarily damaged, as shown by the presence of albumin in the urine from this kidney. Of the 197 patients who could be traced, 138 were still alive, and 59 were dead. The mortality was considerably higher for men than for women, being 35·6 per cent. for the former and only 22·3 for the latter. This difference was evidently chiefly due to the presence of disease in the genital system of the men; in 81 per cent. of the male patients who died, there were signs of combined urino-genital tuberculosis at the time of operation. The operation mortality was only 2·5 per cent. (five deaths within the first six weeks of the operation). Of the 138 survivors, 82 showed complete recovery, and 35 showed recovery with some permanent defect such as a contracted bladder. The remaining 21 patients had not recovered completely. One of the most striking observations emerging from this investigation is that many patients are very long in dying after nephrectomy for unilateral tuberculosis; among the patients who died from disease of the remaining kidney, the average duration of life after the operation was five and a half years. In the absence of post-mortem examinations, it was not always possible to say whether these deaths were due to persistence of the bladder tuberculosis and nephritis in the remaining kidney or to tuberculosis in this kidney. Prof. Suter concludes that permanent recovery can be effected by nephrectomy in 60 per cent. of all cases of unilateral renal tuberculosis.

The Prognostic Significance of Cavities in Pulmonary Tuberculosis.

It has recently been stated in Germany that cavitation almost invariably means the patient's death within a short time, and that it is most rare to find cavities in persons who have recovered from pulmonary tuberculosis and who have died from some other cause. To throw further light on this matter, Dr. K. Lydtin,[1] of Prof. Romberg's clinic in Munich, has investigated the ultimate fate of 2500 consumptives treated in hospital in the period 1912–20. There were 716 who died in hospital, and among them there were about 650 who showed cavities at the necropsy. There were also 121 patients who showed definite clinical or X ray evidence of cavities, and who yet left hospital alive. Only 79 of these 121 patients could be subsequently traced, and it was found that 66 had died, and only 13 were still alive. These figures give considerable support to the gloomy views expressed in 1921 at the German Tuberculosis Congress in Elster by Dr. Graeff, who suggested that there was little use in sending patients with cavities to sanatoriums unless some preliminary operative procedure, such as a thoracoplasty, had been undertaken.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the principal health statistics of six counties for 1922:—

County.	Estimated population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality		Maternal mort. in childbirth.
							Legit.	Illegit.	
Bedfordshire ..	207,916	17·9	12·2	1·0	1·2	2·5	63	111	3·2
Staffordshire ..	710,378	23·0	12·3	0·9	1·1	3·1	84*		3·8
East Sussex ..	253,246	15·6	11·8	0·8	1·5	1·9	52*		4·6
Norfolk	316,976	19·7	12·9	0·9	1·6	—	63	111	—
Lincolnshire (Parts of Lindsey)	254,567	21·1	12·9	1·2	1·2	2·4	71	138	4·1
Hampshire ..	394,665	19·4	11·3	0·8	1·3	1·9	52*		3·6

* Undivided infant mortality.

A line denotes that the information is not given in the report.

Bedfordshire.

Prof. Henry Kenwood believes that for a still further substantial reduction in the infant mortality-rate we must rely on fuller measures of ante-natal work, and he reports that the county scheme, under which the midwives are subsidised to act as ante-natal health visitors, has worked smoothly during 1922. There are still too few maternity hospitals and homes in the county, and the need for a dental service for expectant and nursing mothers is great. The shortage in water-supplies dating from 1921 is still felt in some villages. Dr. Kenwood lays stress on the advantages of earth-closets over the privies and pail-closets usually provided, and shows how easily the latter can be adapted for the use of dry earth and thus rendered more sanitary. The report contains the usual complaint of the dearth of houses and the consequent impossibility of renovating unfit houses. Dr. Ronald T. Herdman submits a separate report as school medical officer. He points out that the raising of the school-leaving age to 14 has created a need for better seating accommodation for the elder scholars, especially the girls, many of whom are found to be stooping and round-shouldered. It is deplored that parents often do not see the need for the provision of spectacles, unless the sight is very defective. This especially applies to the boys, who are expected to take up outdoor work and to do little reading after they leave school. Ear disease is not common among the Bedfordshire school-children, although an examination of 138 leavers showed that 8 had actual discharge. Of the remainder, 6 had a hole in the drum and 23 showed scars, but in most of these there was either only a slight or no defect of hearing. The school entrants have as many bad teeth as formerly, but at the age of 8 there is a marked improvement since the work of the school dentist began. The school dentist, Mr. F. S. Cooper, says the parents are gradually learning about the aims of conservative dentistry. Owing to an insufficient staff, the dental work is mainly confined to children up to the age of 10 years.

---

[1] Zeitschrift für Tuberkulose, 1923, xxxix., 1.

Staffordshire.

Dr. W. D. Carruthers reports that there are now 224 trained and only 66 "bona-fide" midwives practising in the county. Since the Midwives Act came into force 110 midwives have been removed from the roll by the action of the supervising authority. Midwives attended about 80 per cent. of the total births in the county, and sent for medical help on 1992 occasions during 1922, compared with an average of 547 for the five years 1905–09. Of 43 severe cases of ophthalmia neonatorum 3 died from other causes, in one case the sight of the left eye was lost and that of the right eye damaged, and in another case the child lost the sight of the right eye, while the remaining 38 recovered without damage. The county council continue their policy of providing midwifery training for suitable candidates on the understanding that when trained each midwife will practise in a definite area for three years. The income will be subsidised up to £120 per annum if she agrees not to select her cases. In the rural districts the County Nursing Association supply the midwifery service. During the year this Association has sent 13 women to be trained as nurse-midwives. Up to the present no maternity homes have been provided, but use is made of the "Mrs. Legge" Memorial Home at Wolverhampton. The county council have fixed a scale for the recovery of fees for medical attendance under the Midwives Act, 1918. The repayment of the whole fee is not claimed unless the weekly income of the family, after deducting 3*s.* 6*d.* for each child under 14 years of age, exceeds 45*s.* The county health visiting scheme provides for 18 combined school clinics and infant welfare centres in the populous areas around Wolverhampton, Walsall, and Stoke. The attendances of expectant mothers were 504, as compared with 378 in the previous year. Dr. Carruthers reports considerable activity in the improvement of sewage disposal schemes and the prevention of the pollution of the rivers.

East Sussex.

Dr. Alex. G. R. Foulerton reports that 1288 houses were completed during the year, 569 under housing schemes and 719 by private enterprise. In view, however, of the serious overcrowding and the cessation of building during 1914 to 1919, existing conditions are not satisfactory, and but little relief has been given by the additional houses provided. The total number of infants born in the county area (exclusive of Hove) during 1922 was 3464. Of these, 2582 confinements were attended by midwives, in 80 per cent. of cases alone and in 20 per cent. acting as maternity nurses. The Maternity and Child Welfare Committee have provided subsidised lying-in accommodation at the Brighton Hospital for Women for 42 cases, and the Crowborough Cottage Hospital for one case. The county council's health visitors have coöperated closely with the East Sussex Nursing Federation. Dr. Foulerton lays emphasis on the great importance of a proper dietary including fresh vegetables and the right kind of fat in preventing tuberculosis, and instances the experience of this country and other countries both during and since the war in support of this view. The continuous fall in the death-rate from pulmonary tuberculosis in East Sussex since the Armistice was interrupted by a slight rise in 1922.

Norfolk.

Dr. J. T. C. Nash reports a considerable advance in the number of new houses erected in 1922. Only 7 new houses, however, were erected in King's Lynn, and unfit houses are still occupied in that borough. Many of the district medical officers of health comment on the fact that the houses provided under municipal schemes are beyond the means of agricultural labourers and others whose earnings do not exceed 30*s.* a week. The lack of new houses of low rental makes it difficult for the sanitary authority to deal effectively with cottages which have become structurally dangerous or are in need of extensive repairs. In the county of Norfolk, in contrast to most other districts, the majority of the births are still attended by doctors. Out of 6248 births only 1353 were attended by midwives alone. Out of these 1353 confinements the midwives sent for medical aid in 238 cases. The Norfolk Nursing Federation exists for the purpose of training, supplying, and supervising nurses, and receives grants from the county council. There are now 83 affiliated nursing associations in the county. The nurses of these associations are used by the county council as health visitors, except in those districts where their three whole-time health visitors work. Dr. Nash draws attention to the need of the encouragement of breast-feeding. While 87 per cent. of the infants under 1 month were breast-fed, 22 per cent. of the infants between 1 and 3 months old and 33 per cent. of those between 3 and 6 months were not breast-fed. There was no shortage of water in Norfolk during 1922.

Lincolnshire (Parts of Lindsey).

Dr. R. Ashleigh Glegg says that the health service of the county is incomplete in certain directions. A maternity home is needed at Scunthorpe. The building formerly used as council offices by the Frodingham Council would be suitable for the purpose. Home-helps are needed during the confinement period. The policy of providing midwives in country districts by grants-in-aid to district nursing associations should be extended. As regards tuberculosis, earlier notification is needed; the provision of hospital accommodation for acute and advanced cases is necessary; better arrangements should be made for after-care and employment after the sanatorium treatment, and the extension of district nursing for advanced cases treated at home is another need. As regards venereal diseases, Dr. Glegg advocates an additional clinic at Gainsborough, some form of notification and legislation to compel treatment until cure is effected. Dr. Glegg draws special attention to the Cleethorpes educational and publicity campaign initiated by the enthusiasm of Mr. Foster, the cleansing superintendent. This campaign has reduced the amount of refuse to be collected "through householders developing a health conscience and burning decomposable refuse."

Dr. Annie T. Brunyate, the maternity and child welfare medical officer, reports that the health-visiting scheme improves as the increasing number of district nurses who act as health visitors extend its operations to outlying areas. There are still large tracts of country, especially in the Wold area, where there are no midwives and no provision is made for the skilled nursing of the mother at her confinement. The amount of dried milk distributed below cost price was less in 1922 than in 1921, partly owing to the revival of industry in Scunthorpe and the ironstone area, but chiefly owing to Government action in cutting off the supply for children over 12 months of age. The effect of this latter step was found to be harmful, but real injury to the health of a considerable number of young children was averted by the (voluntary) Child Welfare Association finding the money to continue the supply on the old lines. Dr. Brunyate thinks that owing to the reduction of the agricultural wage it will be necessary to provide more milk in country areas if the standard of health of children of large families is to be maintained. The dental treatment provided under the county council scheme is greatly valued by the mothers; free dentures are very rarely provided under this scheme, and it is hoped that in the future the care committees will be able to give more assistance for necessitous cases.

Hampshire.

Dr. Robert A. Lyster is not pessimistic as regards the effect of expenditure on tuberculosis schemes. He points out that a comparison between the triennium 1906–08 with the triennium 1920–22 shows a fall in the general death-rate of 4 per cent. and a fall in the death-rate from pulmonary tuberculosis of 25 per cent. The lack of early notification constitutes the chief obstacle to progress. He expresses regret as to the delay in the provision of a county sanatorium. The work in connexion with maternity and child welfare centres flourishes; the number of centres is now 56. There are only two medical officers. This work costs the county council but little, £300 being voted annually towards the finances of the centres, in addition to trifling amounts towards rent and the necessary travelling expenses of the medical officers and nurses who attend. The inspection of midwives is carried out chiefly by the superintendent of the Hampshire County Nursing Association (to which the county council makes a grant for the purpose). As the result of inspections, 17 midwives were reported during 1922 to be unsatisfactory in some respect and received the necessary warning. The provision of midwives for every part of the county has received much consideration from the county health committee, and as the result the county council has been recommended to make an additional grant of £600 a year to the County Nursing Association on the understanding that the Association will provide midwives in every part of the county not already dealt with. Dr. Lyster comments forcibly on the deception of the public by the trade use of such terms as "egg substitutes" or "egg powders" for preparations which consist of baking powder mixed with colouring matter and starch and in no way resemble eggs in food value.

SCHOOL MEDICAL SERVICE.

Cheshire.

OVER 23,000 individual children were examined during the year, and including those examined by the two school oculists and the school dentist, 11,579 children were referred for treatment. Of these, 64 per cent. completed treatment. During the year the rate-aided operative treatment of enlarged tonsils and adenoids was suspended as part of the economy campaign. Dr. Meredith Young points out how no one who knows the position of the working classes to-day can doubt that there are very many cases where it is quite impossible for the parents to pay even a shilling or two towards an operation of this kind, and he expresses the hope that this form of treatment may be resumed quite soon. Dental disease was recorded in 6 per cent. of those inspected by the assistant medical officer. The school dentist referred 80·3 per cent. of the 6603 whom he inspected for treatment. The large discrepancy between these findings is explained by the fact that the assistant medical officers refer for treatment only the cases where three or more teeth are carious or where sepsis is present; also the dentist's examination is a more searching examination by means of probe and mirror, which goes to show how important is the dentist's inspection. One dentist for the whole of Cheshire seems now inadequate.

One of the assistant medical officers, Dr. W. J. McIvor, reports that he found round shoulders often masking lateral deviation or scoliosis in as many as 1·6 per cent. of the children, "which figure, although far short of that found in secondary schools, suggests that the seeds of deformity are laid early. . . . In some schools the older children are forced to occupy seats made for far younger children, and consequently sit in a regrettably crouched attitude, there being a scarcity of seats of suitable type, while at the same time in other schools in the same area, where the attendance has decreased, there is a surplus." Dr. McIvor suggests that a transfer of seats from one school to another might be made. The prevention of developmental defects, such as spinal curvature, flat-foot, and myopia, is an important branch of school hygiene.

County of Stirling.

During the period from August 1st, 1922, to July 31st, 1923, the total number of children medically examined, including the 16-year-old group, was 10,202, which number comprises 1925 special examinations. Roughly, one-third of the school population was examined. There is one whole-time and one part-time dentist employed for the whole county. The part-time dentist is employed only in the borough of Stirling. Here he found 816 children requiring attention, of whom 128 refused treatment. To get the remainder treated necessitated 1118 visits of the school nurse. In the county it was found that 90 per cent. of the children inspected required treatment, and Dr. Thomas Adam emphasises the necessity for extending treatment to children over 8½ years of age. The total number inspected was 7291, of whom 1249 received treatment, considerably more than double the number treated last year. The increase is attributed to the fact that the education authority have reduced the fee for treatment to 1*s.* from 3*s.*

Dr. Margaret Rutherford, one of the assistant medical officers, writing on employment of children out of school hours in one of the more populous areas of the county, reports: "In spite of the fact that no child apparently suffers from employment, it is to be deprecated that so many of these children are employed for more than 18 hours a week—e.g., one boy who is employed by a dairyman and by a butcher works 40 hours a week, and another boy employed as a cigarette carrier at the railway-station, works 37 hours a week." Twenty-eight of the 95 children examined in this connexion were under the age of 12. Four of them were employed as lather-boys in barbers' shops. The number of children suffering from skin disease was considerably higher than in the previous year. Impetigo was the prevalent disease, and Dr. Adam reports that he recommended the abolition of the school lavatory towels in several instances, "as there is no doubt that in a great many cases infection is conveyed by the use of these towels." Impetigo is, after all, a disease spread by dirty conditions, and though the communal towel is undoubtedly a vehicle of infection, the towel itself is surely a necessity for practical cleanliness. It would in the long run probably have been cheaper to increase the number of towels, but it requires great determination and diplomacy to educate public opinion to appreciate this.

Aberdeen.

The report of the school medical officer, Dr. George Rose, last year dealt in detail with the very insanitary condition of certain of the schools. It is interesting to read that there has been a "straightening up" in general hygiene in the Aberdeen schools, although much has still to be done. Dr. Rose again returns to the need for spray baths. "The baths have not materialised, but there has been a troubling of the waters," and he exhorts the town council, seeing that the expense of swimming ponds is so great, to concentrate on baths where school-children might have a bath once a week during school hours, and adults have the like privilege in the evening. "Many of our townsmen follow occupations which are grimy and dirty, and it is but fair that those who do our unpleasant but necessary work should be afforded the possibility of making themselves clean at a small cost. . . . Accustom a child to a clean body and the habit will continue through life." We hope that Dr. Rose's arguments will prevail.

A comparison of war and pre-war heights and weights showed that the physique of the older school-children had not suffered from the food rationing, nor by the replacement of pre-war articles of diet by substitutes. The question as to whether the scarcity of milk during the war had injured the babies born at that time, Dr. Rose goes on to say, was the only question that awaited an answer. "That question can now be answered in the negative, for the heights and weights of the past school year show no practical difference from those of pre-war times. Our children have passed through the war scathless. They have no arrears of malnutrition to overtake or to be a mortgage on their health and energy in the future, as is the case among the children of Central Europe." There are only two blind children of school ages belonging to Aberdeen, and these are being educated at Craigmillar in Edinburgh. A class for stammerers has been started. Indeed, Aberdeen appears to have a true conception of the meaning of school hygiene, and in practical application of the term is going ahead steadily. Dr. Rose's reports are always good reading, and he is generally at pains to explain to the authority his reasons for any new step he contemplates. His exposition of the methods for ascertaining the degree of mental defect by intelligence tests is clear and comprehensive.

With reference to the proposals of certain eugenists for the prevention of mental deficiency, arguing that the benefit of the individual should have first consideration, he writes: "There is enough to be done in the carrying into effect of the provisions of the Mental Deficiency and Lunacy Act that provides for the protection of the feeble-minded female and for the restraint, instead of punishment, of the feeble-minded criminal, for these provisions have been comparatively ignored. Let others dream of Utopia. Our time and energy would be better spent in keeping our own doorstep clean."

MENTAL HOSPITALS SERVICE.

IN the annual report of the *Devon Mental Hospital* for 1922 it is recorded that the laboratory has been reopened, and that an operating theatre is under consideration. It is also pointed out that the hospital needs a dental room, verandahs, continuous baths, and ward letter-boxes. The diet has been improved, but is still open to criticism in view of the prevalence of tuberculosis, both the rate of incidence and the death-rate from this disease being considerably higher than the average for British mental hospitals. It is mentioned that the nurses are encouraged to make notes on their cases, these notes being incorporated in the clinical records; the practice may be found of value both to the nurses themselves and to the medical officers.

The *Bucks County Mental Hospital* was overcrowded during the early part of last year, but the return of 142 out-county patients to Oxford has left it in comparatively easy circumstances. Nevertheless, the hospital appears to be understaffed; there are only two medical officers to 609 patients, and the Commissioner observes that the ratio of nurses to patients is unusually low. The maintenance-rate has been reduced to 17*s.* 6*d.* per week.

It was feared at one time that the accommodation at the *Inverness District Asylum* would prove inadequate for the needs of the district. It has, however, remained sufficient, owing, it is stated, to the decreasing population of the Highlands, and further, to a policy of boarding-out suitable cases under single care. Many of the able-bodied patients have been employed for some years on building a reservoir, which is now nearing completion.

The report of the Inspector-General of the Insane, *Victoria* (*Australia*), for 1921, has for some reason not seen the light until 1923. It is a vigorously worded document, demanding numerous reforms of a nature with which we are familiar in England. The chief difficulty is represented by old and unsuitable buildings; one of these is likely to be given up altogether. Although in some respects Victoria appears to be worse off than England in accommodation for the insane, one feature of their organisation is an admirable one which is likely to be followed universally in the course of time, and that is the provision of large and totally independent "reception houses," where recent cases only are received, including voluntary boarders. For our own information it is worth noting that a high proportion of totally irrecoverable cases are sent to these places, including general paralytics, senile dements, and epileptic congenital defectives—patients who should be sent direct to an asylum. The sole function of the reception house is the study and treatment of recent and doubtful cases. Even among these, further subdivision is desirable—separate wards, for instance, are needed for noisy patients. The meaning of this is that there are no limits to the adequate and individualistic treatment of mental disorder; "classification" means a great deal more than the asylum architect of the last century ever dreamt of, and perhaps more than is contemplated in some of the rebuilding schemes of the present day.

The report of the Inspector of Hospitals for the Insane, *Queensland*, presents little more than a brief recapitulation of the main figures in the accompanying statistical tables, and it is therefore difficult to gauge from it the outlook of those responsible for lunacy administration in that State. No suggestion is made that facilities for voluntary treatment are desirable. Three "reception houses" exist, where patients are classified and receive preliminary treatment, but one of these has been closed, the reason for this step not being divulged. A commendable arrangement in regard to the nursing staff has been made, certain nurses who have qualified after five years' training being sent for two years to a general hospital, where they may obtain the State general hospital nursing certificate, thus qualifying for the higher posts in the mental nursing service.

The Services.

ROYAL ARMY MEDICAL CORPS.

Temp. Capt. L. C. Martin relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. A. R. Moodie to be Maj. (Prov.).

Capt. E. A. P. Brock (R.A.M.C.), to be Divisional Adjutant 46th (N. Midland) Div., vice Maj. J. R. Yourell, R.A.M.C., who vacates that appt.

ROYAL AIR FORCE.

W. Parsons is granted a short service commn. as a Flight Lt.

FIFTH ITALIAN RADIOLOGICAL CONGRESS.—The Fifth Congress of Medical Radiology, which was recently held in the rooms of the Palermo University, under the Presidency of Prof. G. Scaduto, was remarkable for the great number of medical and technical radiologists taking part. The transactions opened with a paper by Prof. Gortan (Trieste) on Pneumoradiography, and especially on Radiography of Cerebral Ventriculi, illustrated by radiograms showing the technical and clinical details. Prof. Boidi-Trotti (Turin) followed on the X Ray Diagnosis of the Urinary Apparatus, supporting his argument with notes of a large number of cases, and a discussion followed. More than 120 communications were presented to the congress. Profs. Milani, Palmieri, Porro, and Gregori dealt with X ray diagnosis of the alimentary system, and Profs. Balli, Uffreduzzi, Perussia, and Siciliano with exploration of the urinary apparatus. The therapeutical branch of the subject was dealt with by Drs. Attili, Milani, Rossi, Mendoleri, Heuser, Prusciano, Ponzio, and Spinelli. During the congress an exhibition of radiological apparatus was held. At the general meeting of the members the following officers were elected or confirmed in their positions: Chairman, Prof. Bertoletti (Turin); as assistant chairman, Prof. Balli (Modena); as secretary and treasurer, Prof. Ponzio (Turin); and as editor of the *Review*, Prof. Perussia (Milan). The sixth congress will be held in April, 1925, in Trieste, under the presidency of Prof. Massimiliano Gortan, chairman.

FOOT-AND-MOUTH DISEASE.

To the Editor of The Lancet.

Sir,—The Minister of Health, in a recent after-dinner speech, invited coöperation of medical and veterinary science in respect to the present grave epizootic of foot-and-mouth disease. The morbific agent being as yet not isolated, empirical experience may not be without utility. Mine I now offer has, at least, the merit of being practical; for when under orders by telegram I was "smashed" by a Government scared (in view of medical theories of the period) by my successful propagation of variola vaccine in 1891, I was left without menial servants and morally but not officially (no successor having been appointed) in charge of over 100 calves—the property of the censorious Government. Amongst these foot-and-mouth disease appeared. My medical staff, diminished from day to day by necessary transfer from my condemned establishment, gallantly joined me in cleansing and feeding the animals. This, confirmed by further experience acquired in after years in conditions less Gilbertian under a more enlightened Government, showed me that, with care as to feeding with soft food, constitutional symptoms are rarely severe and recovery results; that conducted with care as to supposed infective matter isolation is efficient, and aerial conduction is improbable; that whilst, in absence of knowledge, it is necessary to disinfect (or better, destroy) dung and urine of the infected, the presumable chief media of spread are the discharges of the mouth and hoofs; that the morbific agent is favoured if the site of deposit be moist and, at least under a tropical sun, is virile but a short time; that judging by a single case witnessed the disease in man is trivial.

If there be any truth in the above, it follows that the only interest as to an infected animal is that it be correctly segregated, and, that being arranged, the important part of further preventive measures is the scrupulous searching for, and destruction of, widely scattered infective matter. This implies inquiry as to the origin and daily history of the animal, holding in mind that whilst fields may be in varying degree in parts contaminated, concentration of infection must be expected not solely in byres and within farmhouse precincts, but in paths leading to them and, indeed, wherever the animal had been driven. Railway cattle wagons and their approaches should be especially suspect.

How to meet the requirements of disinfection under such conditions doubtless has been duly met by the Agricultural Department, within farmhouse precincts, by customary methods; but where paths, earthen floors, and scattered and possibly infected straw fragments beyond such areas are concerned, I believe strongly in the use of flaming. In 1899 I made, in the interests of plague prevention, simple bacteriological experiments on discharge—stained earthen floors, with heat produced by kerosene gas compressed in cylinders, which showed this mode could compete with the use of perchloride of mercury solution. In 1903, in the presence of foot-and-mouth disease, I found a more suitable portable apparatus to be a slightly modified Lucal burner which, at small expense, projects a flame of intense heat under absolute control. This in practice gave full satisfaction. At my request, Lieut.-Colonel (then Captain) S. R. Christophers, proved the utility of the apparatus by complete bacteriological experiments. In the absence of a recognised microbe, *B. coli communis* was utilised by him.

The chief effort of the Agricultural Department has been the slaughter of animals at the net cost of £1,161,000. It would seem it has relied too long upon a method that would be justifiable solely at the commencement of an epizootic, in the absence of isolation accommodation and of inspecting staffs; but a stage must by this time have been reached in areas where this first step has been unsuccessful, where it would now be profitable to erect rapidly cheap isolation shelters with impervious platforms at central points, served by staffs vested with compulsory powers of inspection and furnished with motor lorries for transport of animals thither. A system of slaughter pursued beyond the limits thus suggested must result in concealment by owners and, consequently, the object in view be defeated.

I am, Sir, yours faithfully,
W. G. King,
London, N.W., Dec. 18th, 1923. Colonel, I.M.S. (retd.)

THE FUTURE OF THE TUBERCULOSIS CAMPAIGN.

To the Editor of The Lancet.

Sir,—Many who gladly acknowledge the success of the tuberculosis campaign in the past are only too conscious of the greatness of the task before us, and are wondering whether our present methods will suffice to bring us the ultimate success that all hope for.

The question arises, then, what is the world needing in relation to tuberculosis, and on what lines is that need to be met? Are we to concentrate our efforts primarily on the cure of the individual by sanatorium methods? This, of course, would be quite reasonable were our knowledge no more fundamental than that of our forefathers. Such a course, however, would never rid us of the scourge of tuberculosis. The conquest of typhoid, malaria, and small-pox, &c., was attained by working on much broader lines than the mere treatment of individual cases. Has not the time arrived for working on broader and more fundamental lines in relation to tuberculosis? We do rightly in offering the best conditions to the individual to enable him to conquer his disease; and all engaged in sanatorium work can point to cases which for all practical purposes are cured. An article on "Sanatorium Treatment Contrasted with Home Treatment," by Dr. G. L. Cox,[1] is of interest as a demonstration of prolongation of life resulting from the former. Let us then "hold fast that which is good." Sanatorium treatment, particularly with the addition, in suitable cases, of artificial pneumothorax or extra-pleural thoracoplasty, is of tried and proved and established benefit, which no wave of pessimism should deprive us of. Yet the great general question remains untouched. The same may be said of other excellent measures—e.g., the institution of farm colonies, training colonies, and village settlements. Even when we add more definitely preventive measures to our list, such as segregation of infective cases, with its necessary limitations, and educational efforts among healthy and diseased, we still feel that we are doing little more than playing with a situation of vast magnitude and terrible seriousness.

What, then, is the urgent need of our time? We require to get rid of tuberculosis by robbing the bacillus of suitable soil for its development. In other words, a scheme of general anticipatory immunisation is our only hope. This becomes the more evident as we realise that even should our present methods (including the provision of pure milk, and so forth) at length suppress the disease; we should soon lose the degree of immunity that we now enjoy, and become the most susceptible nation on earth, till exterminated by epidemics of acute tuberculosis. We require, then, to replace the haphazard and therefore dangerous means of immunisation that now prevail (through receiving unmeasured doses of living bacilli into our bodies), by methods of immunisation scientific and effective, and withal safe. The greatest national need, then, is a universally applicable preventive remedy applied early in life which will increase the degree of active immunity that we now enjoy. Is tuberculin (whether Koch's, Dreyer's, Nathan Raw's or anyone else's), such a remedy? In the light of Sir Robert

---

[1] British Journal of Tuberculosis, January, 1923, p. 27.

Philip's experience, with perseverance in the percutaneous use of the older tuberculins, we judge that much can be done curatively and presumably preventively. Sir Robert Philip now definitely recommends the adoption of the preventive use of tuberculin. Dr. Nathan Raw advises the same course. Apart from declared results, the suggestion seems reasonable. Can we sit still and do nothing in regard to so pressing a matter? Has not the time come for a commission appointed by the Ministry of Health to make the requisite inquiries and recommendations so as to guide the profession at this juncture? The ramifications of the tuberculosis scheme throughout the land provide the only organisation existent capable of making a concerted effort on the lines indicated. The tuberculosis dispensary, already so valuable, would find a new raison d'être in the provision of that active immunity which is the crying need of the hour.

I am, Sir, yours faithfully,

Sheffield, Dec. 20th, 1923. R. M. FENN.

OPIUM IN CARDIAC DYSPNŒA.

To the Editor of THE LANCET.

SIR,—Dr. Claude Wilson in your issue of Dec. 22nd writes: "I cannot doubt that morphine must frequently have been used in these circumstances [cardiac "asthma"], . . . but apparently very little has been placed upon record." This he concludes from "an extensive though hardly an exhaustive search through the literature of the subject." In the *Practitioner*, 1869, iii., 342, as recorded by Dr. J. D. Rolleston, *St. George's Hospital Gazette*, xvii., Nov. 8th, 1909, I made known the invaluable aid of subcutaneous morphia (which I have found to be better than "opium") in cardiac and uræmic *dyspnœa* ("asthma" is a term belonging to a totally different clinical series). On turning to three popular text-books at hand—Osler, Fagge, and Price—I find its virtues in this agony duly insisted upon. So precious is it that I have hoped that if any words of mine should survive, it would be that he recommended subcutaneous morphia in cardiac dyspnœa (in the first instance against the protests of his colleagues).

I am, Sir, yours faithfully,

Cambridge, Dec. 20th, 1923. CLIFFORD ALLBUTT.

THE TREATMENT OF PYREXIAL TOXÆMIAS WITH ANTIPYRETICS.

To the Editor of THE LANCET.

SIR,—Since Sir Archdall Reid [1] and later other observers have advocated the above treatment I have used the same methods in five different cases with the striking results given in the following short résumé.

1. A case of puerperal fever occurring on tenth day; midwife's case, in which I was called in to suture perineum; wound healed primary intention, but fever of 102° F. and pulse-rate 120 on date mentioned. No physical signs except malaise; antipyretic treatment ter die. Result, temperature normal in 48 hours; no further trouble.

2. A very debilitated woman with physical signs strongly suggestive of pulmonary tuberculosis, but sputum negative. Temp. 102°–104° F., pulse 130; condition grave. Same treatment; normal temp. in three days; no further pyrexia and gradual return to health except, of course, the physical signs in chest still remain, though to a less marked extent.

3. Case of puerperal *B. coli* pyelitis with high fever (up to 104·2° F.) and unaccompanied by rigors; flooded with alkalies, as so strongly advocated by Mr. Frank Kidd, my late chief at the London Hospital, and antipyretic treatment, p.r.n. In this case I reduced the temperature on one occasion by 6° to normal in four hours with simply 10 gr. of aspirin. Profuse sweating occurred, followed by refreshing sleep. The alkali treatment, of course, in this case was of primary importance, but here the promotion of free sweating with accompanying reduction of temperature was a most useful adjunct, the skin acting as an accessory kidney in the elimination of toxins.

4, 5. Two cases of adult lobar pneumonia; crisis in two days: respiratory distress for one day only. These two cases were remarkable for the absence of the distress so often seen in adult lobar pneumonia. In the first case the patient was sitting up in bed in two days working out football competitions, and his wife pooh-poohed the idea of pneumonia, though his right lower lobe presented all the classical physical signs of that condition. The second case when first seen had a temp. of 104·4° F., with delirium, and, as before stated, in 48 hours the temp. was normal and all anxiety passed. The lung condition, of course, goes through the ordinary process of resolution, but any treatment which banishes the distressing respiratory embarrassment which is so prominent a feature of this serious condition is well worth a trial.

For the use of your readers who are not familiar with Sir Archdall Reid's proposals as to treatment I may state that they are the exhibition of an antipyretic powder, as follows:—

Pulv. ipecac. co., gr. v.
Aspirin, gr. x.
Phenacetin, gr. v.

I myself have not strictly adhered to the above formula, sometimes incorporating quinine as well as the other drugs. No ill results follow (stimulants are given p.r.n., especially after the profuse sweating that occurs). The elimination of toxins in the sweat seems to be the secret of this treatment, and it is one that is well worth a trial in all forms of pyrexial toxæmia, being simple, inexpensive, and efficacious.

I am, Sir, yours faithfully,

Exeter, Dec. 15th, 1923. CHARLES H. CARROLL.

---

[1] THE LANCET, 1921, i., 1211.

THE SHORTAGE OF NURSES.

To the Editor of THE LANCET.

SIR,—With reference to a letter in your issue of Dec. 15th on the shortage of nurses, I should like to say how strongly I agree with Miss Gertrude Cowlin in concluding that to establish a subsidiary nursing service would result in a poor nursing service for the community. In Russia this method has been in practice for many years, being the system adopted at the same period that Florence Nightingale propounded our present system in England. I had the opportunity of seeing the results—i.e., the care of acute illness by women totally unfit and untrained to carry out skilled nursing, the "Na-na"; and the qualified or fully trained nurses performing duties which would usually be confined to the medical profession in this country. The system has served to create, with the "Feldshers," men and women who undergo a short medical course of two years, terminated by examination, a subsidiary medical service, which has led to the majority of the poorer members of the community receiving no really skilled treatment, either medical or nursing. The present commissar of health, realising that the existing system does not provide the best outlook for the people, has invited help from British nurses to establish in Moscow a training school for Russian nurses under the English system.

I am, Sir, yours faithfully,

MURIEL A. PAYNE, S.R.N., A.R.San.I.

Woodford, Essex, Dec. 17th, 1923.

EDINBURGH ROYAL INFIRMARY.—At a meeting of the League of Subscribers, Sheriff Crole, member of the Infirmary Board, stated that the finances of the infirmary were now in a sound position. The expenditure for the past year amounted to £119,810, an increase of only £50 over the previous year, although the number of patients treated had greatly increased. Considerable economies had been effected, but efficiency had in no way been impaired. The cost per bed per annum was now £133 11*s.* 4*d.*, representing a decrease of £3 2*s.* 11*d.* from the previous year's figure. The total ordinary income had increased to £110,150 from £99,171. The voluntary contributions amounted to £68,721, an increase of £3009 for the year. This, he said, was another triumph for the voluntary system of hospital maintenance. The proposal to add two small wards to the ear, nose, and throat department, at a cost of about £12,000, will shortly materialise, and an extension in connexion with the X ray department is contemplated. Although the number of people who received treatment was large—15,043 in-patients and 46,693 out-patients—there was a waiting list of 17,000 to 18,000, and extension was urgently needed.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a Congregation held recently the following degrees were conferred:—

M.D.—A. W. Uloth, Pembroke; E. H. R. Altounyan and E. Wordley, Emmanuel.

M.B. and B.Ch.—E. Tagoe, Christ's.

M.B.—R. N. P. Wilson, Pembroke; G. H. Caiger, Caius; and C. Dunscombe, Downing.

At recent examinations the following candidates were successful:—

Third Examination for Medical and Surgical Degrees.

Part I., Surgery, Midwifery, and Gynæcology.—E. V. Beale, King's; F. M. Collins, Pembroke; H. V. Coverdale, R. Cove-Smith, and W. H. Craib, Caius; G. J. V. Crosby, Christ's; D. E. Cuffey, Pembroke; J. R. B. Dearden, John's; V. W. Dix, Trinity; J. H. Doggart, King's; R. B. Fawkes, Queen's; W. H. Gervis, Caius; R. A. Highmoor, Clare; J. W. Hope Simpson, Trinity; R. Jackson, Downing; J. P. W. Jamie, Emmanuel; W. A. Lister, Trinity; H. R. Matthews, Corpus Christi; G. A. Metcalfe, Jesus; H. D. N. Miller, Down; S. M. Milner, King's; E. G. Morris, Clare; J. Ness-Walker, John's; C. E. Newman, Magdalene; G. G. Penman and A. D. Porter, Pembroke; E. A. B. Pritchard, King's; R. H. T. Rea and R. L. Rhodes, Caius; W. L. Roberts, Clare; R. A. M. Scott, Emmanuel; W. G. Scott Brown, Corpus Christi; F. A. H. Simmonds, Emmanuel; L. V. Snowman, Down; G. L. Thompson, Trinity; G. K. Thornton, Corpus Christi; K. W. Thorp, Caius; F. C. O. Valentine, Magdalene; S. Vatcher, Trinity; A. L. Walker, Pembroke; R. K. Wilson, Trinity House; F. R. Winton, Clare; and H. Yates, King's.

Part II., Principles and Practice of Physic, Pathology, and Pharmacology.—J. C. Ainsworth-Davis, Christ's; L. J. Bendit, Queen's; N. E. Chadwick, John's; W. H. Craib, Caius; F. E. Graham-Bonnalie, Christ's; G. T. Henderson, Caius; E. G. Holmes, Christ's; J. W. Hope Simpson, Trinity; R. Jackson, Down; L. P. Lockhart, Caius; C. A. Lupton and R. J. Lythgoe, Trinity; T. K. Maclachlan, Pembroke; F. H. Mather, Sidney Sussex; G. A. Metcalfe, Jesus; G. C. Millis, Queen's; E. S. Page, House Selwyn; R. J. V. Pulvertaft, Trinity; B. E. Schlesinger, Emmanuel; M. H. Webb Peploe, Trinity; R. H. White, King's; R. K. Wilson, Trinity House; and G. M. Brown, Girton.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on Dec. 19th the Vice-Chancellor, Mr. H. J. Waring, being in the chair, Dr. Eleanor M. Scarborough was appointed as from Jan. 1st, 1924, to the recently-instituted readership in Pharmacology tenable at the London School of Medicine for Women. She has held resident clinical appointments at the Elizabeth Garrett Anderson Hospital and at the Royal Free Hospital. In October, 1919, she was appointed demonstrator in pharmacology at the London School of Medicine for Women, and since 1921 she has been assistant lecturer in that subject at the school. Prof. Hugh MacLean was awarded the William Julius Mickle Fellowship (of the value of £200) for 1924 in respect of the work which he has carried out during the past five years in experimental medicine. This Fellowship is awarded annually by the Senate, under the terms of the Mickle bequest, to the man or woman who, being resident in London and a graduate of the University, has done most to advance medical art or science within the preceding five years and has therein shown conspicuous merit.

At examinations held recently the following candidates were successful:—

M.D. Examination.

Branch I., Medicine.—John V. C. Braithwaite, Guy's Hosp.; Rhys T. Lewis, Univ. Coll. Hosp.; Montague Maizels, Guy's Hosp.; Merell Philippa Middlemore, London Sch. of Med. for Women; and Manek Jamshedji Panthaky, King's Coll. Hosp.

Branch III., Psychological Medicine.—Mary R. Barkas (University Medal), St. Mary's Hosp.

Branch IV., Midwifery and Diseases of Women.—Sybil G. Mocatta (University Medal), St. Mary's Hosp.

Branch VI., Tropical Medicine.—Trevor L. Bomford, St. Bart.'s Hosp.

M.S. Examination.

Branch I., Surgery.—Hugh J. McCurrich, Bristol University and St. Bart.'s Hosp.; and Alan C. Perry, London Hosp.

UNIVERSITY OF SHEFFIELD.—The following students have recently passed the Final Examination for the degrees of M.B., Ch.B.

George Ritson Bailey, Lancelot Harry Copping, Thomas Ronald Forsythe, Cyril Handley Greaves, Carl Myers, John Emmet Tannian.

UNIVERSITY OF MANCHESTER.—At examinations recently held the following candidates were successful:—

Final M.B. and Ch.B. Examination.

New Regulations.

C. N. Aldred, William Broadhurst, J. F. Bromley, Bessie E. Cook, R. W. Fairbrother (distinction in Obstetrics), Madge E. Heywood, Bertha Kahn, L. W. Kay, A. C. Kelly, V. F. Lambert, W. B. McKelvie, Marjorie M. O'Dea, R. W. Parker, Marjorie Robinson, Kate B. Scott, Agnes Seaston, H. F. Shaw, Marjorie Thompson, Sarah Walker, Jane M. Wilde, and Marjorie Youatt.

Obstetrics and Surgery.—R. S. Adam, Margaret A. Bromhall, W. C. V. Brothwood, T. A. Brown, J. A. Crowther, Mary S. Davies, T. E. Davies, Reginald Ellis, Leo Fay, C. R. Fielding, A. G. Forbes, Anne H. Glancy, J. W. Graham, Philip Gregory, Edward Holmes, Winifred L. Horton, J. N. Hudson, Phyllis Kaufmann, David Kemp, Hilda M. Linford, F. R. Lockhart, Samuel Pope, L. J. Prosser, Albert Riley, Eileen Sheehan, Dorothy Simmons, John Sims, G. S. Smith, A. R. Somerford, James Troup, H. M. Turner, Charles Wilcocks, and Geoffrey Williamson.

Obstetrics.—J. H. Anderson, Solomon Bernstein, Madge E. Edwards, P. G. Johnston, Alice M. Orrell, R. F. Stubbs.

Forensic Medicine.—C. E. W. Bower and Gladys F. A. McLean.

Hygiene and Preventive Medicine.—C. E. W. Bower, Charles Eccleston, Gladys F. A. McLean, W. M. Roberts, H. C. Smith, and Eric Whiteside.

Third M.B. and Ch.B. Examination.

Pathology.—Louise Aronovich, H. K. Ashworth, Marion L. Bainbridge, C. H. Bamford, A. R. Barber, J. R. Beal, Pieter Bester, R. H. Blackburn, *N. W. Bolton, Lilian Bond, G. H. H. Booth, Kathleen M. Boyes, Lillie M. Burton, Marguerite E. Cliff, T. K. Clifford, John Crook, T. A. Danby, A. A. Davis, N. E. Delaney, L. F. Evans, Mary Evans, J. D. Farquhar, Barnett Fink, S. J. Firth, Riad Girgis, Dorothy Guest, T. S. Hanlin, Zaky Hanna, Mary Harburn, F. S. Hawkins, Barnett Hirsh, G. D. Hithersay, J. L. Holt, *R. L. Holt, John Hunt, E. P. Hyde, May Johnson, Walter Johnson, G. W. Jones, J. T. C. Keddie, J. H. Kitson, C. T. Marshall, W. D. Mitton, S. L. Mucklow, Archer Pearson, Harry Pigott, R. H. Poyser, *Joan Robinson, M. R. Sagar, N. F. Seed, Raphael Shaffer, W. H. Shepley, A. D. Shubsachs, W. S. Slater, Agnes G. Smiley, *F. H. Smirk, Graham Stenhouse, Jane B. Stubbs, J. K. Thomas, Jacobus Viljoen, J. C. Wilson, and Reginald Wood.

* Distinction in Pathology.

Pharmacology.—R. S. Abraham, Agnes M. Bodoane, Gerald Bradley, Gladys Brocklehurst, J. F. Caithness, D. E. Francis, Zaky Hanna, L. C. Peringuey, Mary I. Prentice, Francis Reynolds, Evelyn I. M. Sheppard, W. C. D. Walmsley, and R. T. Wimmer.

UNIVERSITY OF GLASGOW: NOMINATIONS TO FELLOWSHIPS.—The following awards have been made by the Senate:—

Faulds Fellowship in Medicine: Dr. John M. Johnston. Senior Arnott Prize, Physiological Physics: David P. Cuthbertson, B.Sc., and Herbert H. Pinkerton (equal). Junior Arnott Prize, General Physics: William A. Mackey. James Macfarlane Bursary: William A. Mackey and William F. Greer (equal). Lorimer (Medical) Bursary in Botany: William A. Mackey. Lorimer (Medical) Bursary in Physics: John M. Brewster. Mackintosh Bursary in Mental Science: Max Gorfinkel. Walton (Medical) Bursary: James Morrison. Brisbane (Medical) Bursary: Alan A. MacDougall, M.A. Dr. Thomas Gibson (Medical) Bursary: Annie B. Price. Joseph Coats Memorial Scholarship in Pathology: Dr. Sarah H. Nelson. Frederick William Penman Memorial Scholarship in Pathology: Dr. Sarah Nelson. Arbroath (Medical) Bursary: Herbert H. Pinkerton. Monteith (Medical) Bursary: John Chalmers. Rainy (Medical) Bursary: James Wemyss. Gardiner (Medical) Bursary: David F. Anderson. Andrew Weir (Medical) Bursary: Gavin McCallum.

A house in the neighbourhood of Glasgow University has been gifted to the Students' Welfare Scheme by Mr. J. M. Robertson, of Glasgow. It is to be used as "a professor's house, hostel, or other university purpose calculated to preserve the amenity of the neighbourhood."—The University Library has been left a legacy of £500, free of legacy duty, by the late Mr. J. F. Orr, writer, of Glasgow.

UNIVERSITY OF EDINBURGH.—The University Court, on Dec. 17th, received the offer of £50,000 from the Rockefeller Foundation Trustees for the fuller equipment of the medical teaching and research facilities. This munificent gift is to be devoted specifically to the establishment of a clinical laboratory in connexion with the Royal Infirmary and to complete the endowment of the Professorship of Surgery on a full-time basis. The Trustees have offered, in addition, an annual grant of £1750 for a period of not less than five years, to meet certain salary charges in clinical medicine and clinical surgery. The need for extension in the Edinburgh Medical School has been acutely felt in recent years, particularly in regard to post-graduate teaching, the extension demanding both space and money. While space still remains a problem, the Rockefeller gift should enable the University to enjoy in the future an even higher reputation than it does at present; nor will the additional advantages be merely academic, in no less degree will the patients benefit from them. The proposals for coöperation in the University's plans of rearranging the departments of medicine and surgery were presented to the Rockefeller Trustees by Dr. Richard W. Pearce, the Director of the Division of Medical Education of the Rockefeller Foundation, and the Trustees authorised Dr. Pearce to assist in the realisation of these plans as far as financial coöperation with the Foundation was involved. Before the offer can be formally accepted the permission of the managers of the Royal Infirmary must be obtained for the construction of the necessary buildings. Negotiations will doubtless be opened immediately.

At the graduation ceremonial, held in the M'Ewan Hall on Dec. 14th, the following degrees were conferred :—

Doctor of Medicine.

*Robert C. Begg (in absentiâ), Ronald M'Donald Cairns, Ethel Cassie (*née* Wiseman), †Alexander Dower, Francis Ernest Gunter, William Thompson Hall, Alexander Joe, Isaac H. Lipetz, Andrew M'Farlane (second-class honours), *Douglas Alexander Miller (second-class honours), David H. Russell, and *Claude W. Stump.

* Awarded Gold Medal for thesis. † Commended for thesis.

Doctor of Philosophy.

In the Faculty of Medicine.—Henry Dryerre.

Bachelor of Medicine and Bachelor of Surgery.

James B. Adamson, Harry Allan, Frank Allardice, Ian R. Anderson, David Arnott, James N. Banks, David M. Bertram, Camaralzama C. Boudou, Edmund R. Boyd, Joseph Braithwaite, Jessie R. Brash, Edward H. Brindle, John C. R. Buchanan, Andrew Bury, John M. Caie, Margaret D. Cairns, Kathleen S. Campbell, Roy F. Campbell, James T. D. Clark, James L. Connacher, John G. Cormack, James W. Cromarty, Ewen G. Dalziel, Alexander W. Davidson (second-class honours), John Davidson, James P. Davie, Hendrik A. N. Dippenaar, William G. Dobson, Isabel M. A. Doeg, Leslie G. Drury, Robert H. Dunlop, Lister M. C. Duthie, Robert W. Eason, Margaret G. Falla, William Foote, William M. Ford-Robertson, Walter M. Forster, William C. Fothergill, Donald A. Fraser, John F. Fraser, Eric M. R. Frazer, Laurence S. Frost, Maurice Gelb, George M'K. Gibson, Sydney Gill, Alexander Gillies, Alexander C. Gillies, David Gold, Margaret H. Gordon, Allan D. Gould, Ralph W. Graham-Yooll, Lionel P. Greson, Alexander B. Guild, William F. Hamilton, Herbert C. Haslam-Fox, Leo E. Henderson, Charles V. Hendry, Hieronymus Hoffmann, Ellis G. Hunter, Louis Jaffit, Eric W. C. Jobson, Willian Jones, Morton Kahn, Isabella Kerr, Jenny C. King, Walter H. Kluge, Annie G. Learmouth, John G. Leebody, Alexander Leishman, Robert V. Liddell, Elizabeth M. Lindsay, Robert Lockhart, Graham Louw, David B. Low, Robert I. M'Alley, William N. M'Arthur, Joseph Maccabe, George H. M'Cafferty, Sydney J. M'Cafferty Andrew W. M'Cay, Peter A. M'Credie, Donald Macdonald John D. Macdonald, Robert Macfiggans, Jane Clarke M'George, Janet M'Lean Mackay, David T. Mackie (second-class honours), John B. Mackie, Catherine J. Maclaren, Ian H. Maclean, Samuel R. Macmillan, Duncan A. B. Macnicol, George S. Marr, Ebenezer B. Mercer, Hugh Miller, John Milne, George W. Monro, John V. Neilson, Alexander S. Nicol, James T. B. Nicoll, Bryce R. Nisbet, George Ormiston, Violet Oswald, James R. H. Pasqual, Douglas G. Paterson, William D. Paterson, Ian A. M. Paton, Milorad Petrovitch, Walter J. R. Pickles, Robert K. Porteous, Geoffrey Priestman, Percival V. Pritchard, Walter H. B. Ramsay, William Ramsay, Jeanne V. Rees, Richard E. B. Rees, John J. Robb, George Robson, Alfred Rosenbloom, Robert J. Rosie, Margaret G. Ross, Hyman L. Rubin, Cecil G. A. Salvesen, Robert E. W. Sandison, Alexander Scott, Jocelyn M. S. Scovell, John A. Shaw, Andrew Simpson, George W. Simpson, Ann F. G. Smith, Cornelius R. Smuts, Neil R. Smuts, William R. Sprunt, John P. Stewart, Frank M. Stuart, Thomas R. M. M. Sutherland, William R. Terry, Felix F. du Toit, Thomas S. Torrance, Frank Towers, Elsie M. Walker, Edwin D. M. Wallace, Hugh K. Watson, John H. Watson, Frederick H. Webb, Alexander B. Williamson, Winifred Wood, and George W. Yule.

The Ellis Prize in Physiology has been awarded to Dr. May L. Walker.

Royal College of Surgeons of Edinburgh.—At a meeting of the College held on Dec. 19th the following candidates, having passed the requisite examinations, were admitted Fellows :—

Albert C. Abbott, Thomas G. D. Bonar, Hendrik J. P. Bruwer, Gerrard Burnett, Thomas L. Clark, Robert M. Dannatt, Ernest C. Fahmy, Griffiths J. Hughes, William Ibbotson, Hubert S. Jacobs, Thomas P. McMurray, James H. Rawlinson, Creina Shepherd, Charles H. Thomas, Henry E. Y. White.

Sinnatamby Thambipillai having passed the requisite examination was admitted a licentiate of the College.

University of Dublin, School of Physic, Trinity College.—At examinations held recently the following candidates were successful :—

Final Medical Examination.

Part II., Medicine.—Wentworth A. Taylor (passed on high marks), Patrick K. Dixon, Joseph E. Eliason, John M. Mounsey, Henry Isaacson, Israel Marin, Jan Andreas du Toit, Etienne R. Hafner, Jack A. Levitt, John S. Glasgow, William L. W. Smith, Robert E. Fausset, William F. Whaley, Douglas L. Hemmingway, Gladys Weatherill, Kathleen E. Hill, Alfred J. Beckett, John M'Clelland, Francis C. B. L. B. Crawford, Charles W. J. Ingham, William D. Speedy, Dermod H. F. Milmo, James V. Williams, Pieter C. du Plessis, Anthony B. Monks, Albert V. Wood, and Margaret O'Neil.

Surgery.—Patrick K. Dixon, George F. T. Saunders, Robert L. C. Fisher, Morris Cohen, N. E. H. P. Williams, William L. W. Smith, John L. Stuart, John J. Laing, James E. Deale, Cecil J. M'Quillan, John M'Clelland, Henry W. L. Dale, Louis Harris, Martha Reid, Rudolf Schaffer, Charles W. J. Ingham, James J. O'Grady, Frederick G. Brown, Jack M. Gordon, Isobel G. Smith, Johannes H. Stals, Philip P. van der Merwe, Kathleen E. Hill, James A. MacDonald, Henry Isaacson, Hans J. Hugo, Isabella H. Speedy, Eileen A. Boyd, and Jan Andreas du Toit.

Midwifery.—Desmond K. Lyons, John K. S. Thompson, Otto G. Wilde, George A. Cowan, John R. Bradshaw, and George Robinson (all of whom passed on high marks), Lewis C. Brough, James S. Armstrong, Simon Wigoder, Louis E. J. Werner, John A. MacDonnell, John N. Atkinson, John H. Bowyer, Wilfred H. Anderson, Robert E. Steen, Dorothy J. Booth, François J. Swanepoel, James W. Wallace, Lionel S. Levitt, Cornelius J. N. Loubser, Kenneth F. Mackenzie, Leslie M. Whitsitt, James L. Marshall, Joseph Morris, John L. F. Steele, Jerreth Horwich, William A. Dickson, Charles J. du Plessis, Godfrey W. Garde, Robert Warnock, John D. Watson, William A. Redmond, Eileen Brangan, Norah M. Gilcriest, Paul N. H. Labuschagne, Richard L. G. Proctor, Israel Strasburg, Herbert Birney, Alexander L. Dobbyn, Raymond J. G. Hyde, Bertha H. Lawler, Paul D. Piel, Herbert W. Strong, Lucy E. R. Pigott, Dorothy I. Henry, Howard St. George McKenny, Robert G. F. Thompson, George D. Rankin, Ralph A. Webner, Robert W. Harte, Louis P. Sayers, and Angel Valentine B. Crawford.

Final Dental Examination.

Dental Surgery and Pathology ; Dental Mechanics and Metallurgy ; Orthodontia.—John C. M. Shaw, John H. B. Tuke, Frances E. Bailey, Thomas R. Wall, James A. N. Dickson, and Maureen Claire Mulhern.

Royal College of Physicians and Royal College of Surgeons in Ireland Conjoint Examinations.—At examinations held recently the following candidates were successful :—

Third Professional Examination.

Sybil Atkinson, Abraham Clein, C. W. Coffey, W. Gilbert, J. Graff, J. P. Hederman, T. T. Joyce, Kathleen Keirans, E. H. McGinty, E. G. H. McNally, J. J. McSharry, A. H. Mackay, G. A. Moorhead, P. J. Mulcahy, J. C. Murphy, W. G. Myers, J. O'Neill, C. A. O'Riordan, T. S. Osborne, J. Rafferty, J. F. Scales, E. Whelan, and D. G. White.

Final Professional Examination.

Francis J. N. Carney, Andrew E. Clements, Michael H. Dobbyn, Francis D. Fitzpatrick, William G. C. Fitzpatrick, Henry I. Hawkes, Rosaleen H. Hoskin, Kathleen O. M. Kennedy, Catherine M. King, George A. Little, John J. Marlborough, Sarah Matson, Francis McConnell, Edward A. McManus, John J. O'Donnell, James O'Donnell, William O'Neill, Vincent J. O'Toole, Herbert C. Patterson, Gilbert F. Plant, Patrick B. Ryan, Jonathan Unsworth, and Samuel P. Wallace.

Diploma in Public Health.

Thomas K. Reddin and John J. Ryan.

Royal College of Surgeons in Ireland.—At recent examinations the following candidates were successful :—

Final Fellowship Examination.

Charles Cooper, Joseph C. Gillespie, Margaret Holliday, Norman P. Jewell, Robert J. May, Richard W. Power, and Frederick H. Whyte.

Final Dental Examination.

Robert H. England, John I. Hughes, Henry F. B. Kelly, Valentine McCarthy, Kevin V. O'Farrell, and James F. Pegum.

West of Scotland Foreign Service Medical Club.—This Club, which consists of members of the medical profession resident in the West of Scotland, who were overseas on service during the war, held its fifth annual dinner in the Grosvenor Restaurant, Glasgow, on Dec. 18th, the President, Colonel A. Dryden Moffat, M.D., in the chair. There were present as guests of the evening, Dr. Thomas Finlayson Dewar, President of the East of Scotland Foreign Service Medical Club, Dr. William F. Gardiner, secretary of that Club, and Prof. Archibald Main, D.D., of the University of Glasgow.

The late Sir John Walton Browne.—Sir John Walton Browne, who died on Dec. 19th in his 79th year, was consulting surgeon to the Belfast Royal Hospital and to the Ulster Hospital for Children, and was well known as an eye, ear, and throat surgeon. He was the son of the late Dr. S. Browne, R.N., formerly Mayor of Belfast, was educated in his native town, in London, Dublin, and Vienna, and graduated in Arts at the Royal University of Ireland in 1863, taking his medical degree four years later. For some time he had a general practice in Belfast before becoming surgeon to the Belfast Ophthalmic Hospital and lecturer in ophthalmology at the Queen's University of which he was a senator. He was at one time president of the Ulster Medical Society, of the North of Ireland Branch of the British Medical Association, and of the Ophthalmological Section of the British Medical Association when that body held its annual meeting at Belfast in 1909. He was knighted on the occasion of the King's visit to Belfast in 1921.

Sir Robert W. Philip has been appointed an Honorary Physician to His Majesty in Scotland, in the room of the late Dr. David W. Finlay.

Small-pox in England and Wales.—Eighty-nine cases of small-pox were notified in the sanitary districts of England and Wales during the week ended Dec. 15th, the counties affected being Derbyshire, Gloucestershire, Middlesex (Wood Green), Notts, and Anglesey (Amlwch).

We regret to announce the death, on Dec. 21st in Dublin, of Sir Lambert Ormsby, a late President of the Royal College of Surgeons in Ireland, who held the rank of Lieut.-Colonel as Consulting Surgeon to the New Zealand Expeditionary Force.

Cheaper Insulin.—Messrs. Burroughs, Wellcome, and Co. announce that on and after Jan. 1st, 1924, insulin will be supplied by them at the reduced price of 12*s.* 6*d.* per phial containing 100 units (10 doses) in 5 c.cm. A similar announcement by Messrs. Allen and Hanburys and the British Drug Houses, Ltd., was noted in our columns last week.

Welsh National School of Medicine.—The Board of Trustees of the Rockefeller Foundation at their meeting last week agreed to make a donation of £14,000 to assist in the development of the medical unit of the school. The money is to be devoted to the building of laboratories, the provision of part of the initial equipment, and the improvement of clinical facilities for the medical unit at the Cardiff Royal Infirmary.

Metropolitan Hospital Sunday Fund.—The annual meeting of this Fund was held at the Mansion House under the presidency of the Lord Mayor of London on Dec. 19th, when the report showed that the collection for the year amounted to £93,892, or £6997 less than the previous year's total. The collections in the places of worship amounted to £43,167, or £5449 less than in 1922. Donations also showed a decrease. Hospital Sunday, 1924, was fixed for June 22nd.

Remuneration of Insurance Practitioners.—Meetings of the Court of Inquiry have been arranged for Friday, Jan. 4th, and Monday and Tuesday, Jan. 7th and 8th, at 10.30 a.m., at the Ministry of Health. These meetings will be open to the public and the press. The Court will hold such further meetings as may be necessary. Approved societies wishing to submit evidence to the Court are asked to communicate with the secretary, Mr. R. H. Crooke, Ministry of Health, Whitehall, S.W. 1, enclosing a statement of the nature of the evidence which they wish to give.

Mental After-care Association.—This Association for poor persons convalescent or recovered from institutions for the insane is urgently in need of funds to carry on and extend the work. Last year over 944 persons were assisted, the majority of whom have done well. The prevention of relapse is one of the chief objects of the Association. Contributions will be gratefully received by the secretary, Miss Vickers, Church House, Dean's Yard, Westminster, London, S.W.

Queen's University Club, London.—A dinner of the club, followed by a musical programme and dance, was held on the evening of Dec. 13th at the Criterion Restaurant, Piccadilly. The members and guests, of whom there were over 100 present, were received by Dr. and Mrs. J. J. Redfern, of Croydon. Membership, without nomination, was declared open to those eligible as past and present students of Queen's University, Belfast, on payment of entrance fee and subscription before March 1st, 1924, to the Hon. Treasurer, Mr. R. A. Kerr, 17, Wimpole-street, London, W. Full particulars may be obtained from the Hon. Secs., Mr. W. McK. H. McCullagh, 152, Harley-street, W., and Dr. E. G. B. Calvert, 17, Wimpole-street.

North-West of England Obstetrical Society. The Presidential address to the Society was delivered by Prof. Blair Bell, in the rooms of the Liverpool Medical Institution on Dec. 20th last. The subject was Investigations into the Use of Lead in the Treatment of Malignant Disease, and was dealt with from its chemical, biological, and pathological aspects. Prof. Blair Bell told how his attention had been drawn to the possibilities of lead in this direction from a consideration of the action of the metal upon the chorion epithelium of the young embryo, a tissue which he regarded as a half-way stage between normal and malignant growth. But lead poisons not only chorion epithelium but also testis, ovary and nerve tissues, all being structures rich in phosphatide substances. The discovery that malignant growths were rich in phosphatides in proportion to their activity held out the hope that they too might be vulnerable. With the help of an able and distinguished band of colleagues, Prof. Blair Bell set himself to work out exactly the biological and toxic properties of lead, and certain new and valuable facts were discovered. The effect on the heart's action, the interference with kidney function, and the changes in the red blood cells were carefully studied in their earliest phases, with corresponding advantage to the clinician in enabling him to gauge his doses with safety. Particular stress was laid on punctate basophilia in the red cells and diminution in the amount of the urine. With increasing knowledge, toxic symptons were becoming infrequent. The chemistry of the interaction of lead salts and the phosphatides was a difficult and complicated subject, and the effect of lead on pure lecithin, for instance, very hard to estimate. The evidence went to show that the mixed phosphatides found in the body were precipitated. The actual preparation of lead employed was a colloidal solution of lead stabilised by the addition of calcium. In practice this is injected intravenously, but it is hoped that a compound with cod-liver oil, used intramuscularly, may prove an efficient substitute. Previous to the meeting a few cases had been shown of inoperable cases of malignant disease, spheroidal-cell cancer of the breast, sarcoma with almost complete destruction of the scapula, and others, all apparently cured.

Medical Society of Climatology and Hygiene of the French Riviera.—The annual banquet was held at Nice on Dec. 16th and was attended by a large number of doctors practising in the district. Dr. M. Faure (Nice) urged the importance of giving publicity to the beneficial effects of the climate of the Riviera as opposed to exaggerated accounts of the available amusements. He pressed the need of attempting the extermination of flies and mosquitoes in order to extend the popularity of the Riviera into the summer, and instanced the success of the methods applied elsewhere. Dr. Borrel, of Strasbourg, gave a striking description of the good results of such methods in that city. Dr. Samways, of Mentone, contrasted French and English ways of improvements. The French ideals soared too high and often failed in their attainment from their sheer immensity, whereas the English preferred to begin more modestly and achieve something definite, extending their plans as success followed.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday, Dec. 31st.—10 a.m., Mr. Maingot: Surgical Pathology. 2 p.m., Mr. Simmonds: Surgical Out-patients. 2.30 p.m., Dr. Saunders: Medical Wards.

Tuesday.—11 a.m., Dr. McDougal: Electrical Department. 12 noon, Dr. Burrell: Chest Cases. 2 p.m., Mr. Sinclair: Surgical Out-patients.

Wednesday.—10 a.m., Dr. Saunders: Medical Diseases of Children. 2 p.m., Dr. Owen: Medical Out-patients. 3 p.m., Dr. Pernet: Skin Department.

Thursday.—10 a.m., Dr. Grainger Stewart: Neurological Department. 2 p.m., Mr. Bishop Harman: Eye Department. 2 p.m., Dr. Scott Pinchin: Medical Out-patients.

Friday.—10 a.m., Dr. Drummond Robinson: Gynæcological Operations. 2 p.m., Mr. Banks-Davis: Throat, Nose and Ear Department. 2 p.m., Mr. Sinclair: Surgical Out-patients.

Saturday.—9.30 a.m., Dr. Burnford: Bacterial Therapy. 10 a.m., Dr. Saunders: Medical Diseases of Children. 10 a.m., Mr. Banks-Davis: Operations on Throat, Nose and Ear.

Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departments.

Appointments.

Clausen, R. J., M.B., B.S. Lond., has been appointed Anæsthetist to Queen Mary's Hospital for the East-End, Stratford, E.

Coleman, C. J., M.D. Camb., D.P.H., Medical Officer of Health to the Holland, Lincs, County Council.

Galloway, R. L., M.B., Ch.B. Edin., Anæsthetist at the Salford Royal Hospital.

Grant, Marjorie A., M.B., Ch.B. Manch., Assistant School Medical Officer for Stockport.

Pope, H. B. M.R.C.S., L.R.C.P. Lond., Honorary Radiologist to Leeds Public Dispensary.

Renwick, Gordon, M.B., Ch.M. Sydney, Assistant Honorary Surgeon to the Royal Eye Hospital, Manchester.

Russell, G. Herbert H., L.D.S., Honorary Dental Surgeon to Leeds Public Dispensary.

Spinks, A. F. G., M.D., Honorary Physician, Maternity and Child Welfare, Princess Mary Maternity Hospital, Newcastle-upon-Tyne.

Thompson, G. K., M.B., Ch.B. Vict., to be Certifying Surgeon under the Factory and Workshop Acts for Sedbergh.

Jessop Hospital for Women, Sheffield: **Hall**, R. J. B., M.B., Ch.B. N.Z., Senior Resident Officer; **Fawcett**, A. W., M.B., Ch.B. Edin., and **Vickery**, C. E., M.B., C.M. Sydney, Assistant House Surgeons.

Manchester Royal Infirmary: **May-Atkinson**, Mrs. **Kate King**, M.B., Ch.B. Manch., Assistant Medical Officer to the Massage and Electrical Department; **Bryce**, A. G., M.D., F.R.C.S. Eng., Assistant Resident Surgical Officer; **Lund**, J. K., M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. Manch., Assistant Medical Officer.

University of Sheffield: **Morrell**, R. A., M.R.C.S., L.R.C.P. Lond., Lecturer in Radiology; **Wilkinson**, G., M.B., B.C. Camb., F.R.C.S. Eng., Lecturer in the History of Medicine; **Skerritt**, J. H., L.D.S. Eng., Lecturer on Operative Dental Surgery; **Barron**, D. C., M.D., Ch.B. Edin., Assistant Lecturer in Medicine.

Vacancies.

For further information refer to the advertisement columns.

Barnet, Wellhouse Hospital.—Asst. Res. M.O. £150.
Bournemouth, Royal Victoria and West Hants Hospital.—Res. H.S. £150.
Bradford Children's Hospital.—Hon. Asst. S.
City of London and East London Dispensary, 40, Wilson-street, Finsbury-square, E.C. 2.—Asst. Pharmacist. £200.
Galloway Royal Infirmary.—Jun. Res. M.O. £125.
General Nursing Council for England and Wales, 12, York Gate, Regent's Park, N.W. 1.—Examiners.
Hospital for Sick Children, Great Ormond-street, W.C.—Biochemist. £600. Res. Med. Supt. £300.
Hospital for Tropical Diseases, Endsleigh-gardens, N.W. 1.—H.P. £150.
Liverpool, Royal Southern Hospital.—Hon. M.O. Electro-therapeutic, &c., Dept., and Hon. M.O. Electro-cardiographic Dept.
Middleton-in-Wharfedale Sanatorium, near Ilkley.—Asst. Res. M.O. £350.
Nottingham Children's Hospital.—Res. H.S. £150.
Notts County Mental Hospital, Radcliffe-on-Trent.—A.M.O. £400.
Orkney, Parish of Eday.—M.O.
Reading, Royal Berkshire Hospital.—H.P. Also Third H.S. Each £150.
Royal Army Medical Corps.—Commissions.
St. Mary's Hospital, London, W. 2.—Med. Supt. £400.
Sheffield Royal Hospital.—Cas. O. £150.
Union of South Africa, University of the Witwatersrand.—Senior Lecturer in Anatomy. £450.
Warwick County and County Borough of Coventry Joint Mental Hospital.—Med. Supt. £1000.
Westminster Hospital.—S. and Ophth. S.; also Asst. Ophth. S.

Births, Marriages, and Deaths.

BIRTHS.

Bourke.—On Nov. 22nd, at Bhagalpur, India, the wife of Captain U. J. Bourke, L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., I.M.S., of a daughter.

Macleod.—On Dec. 20th, at Lexham-gardens, W. 8, to May Eleanor, wife of Captain D. N. Macleod, M.B., B.Ch. Camb., R.A.M.C., of a son.

Pellow.—On Dec. 17th, at The Hook, Kingsclere, Newbury, the wife of Dr. Pellow, of a daughter.

Smythe.—On Dec. 18th, at Dunkeld, St. Cross, Winchester, the wife of Gerald Smythe, M.D., of a daughter.

MARRIAGES.

Bulloch—Baker.—On Dec. 18th, at St. Augustine's Church, Queen's Gate, William Bulloch, M.D., F.R.S., LL.D., Goldsmiths' Company, Professor of Bacteriology in the University of London, to Irene Adelaide (*née* Peyman), widow of Alfred Augustus Baker.

Cheyne—Bayley.—On Dec. 15th, at the Parish Church, Stenton, W. Hunter Watson Cheyne, M.B., to Grizel, elder daughter of Mr. and Mrs. I. F. Bayley, Halls, Dunbar.

Place—Turner.—On Dec. 22nd, at St. Margaret's Church, Burnage, Thomas Byron Place, junr., L.D.S., eldest son of Thomas Byron Place, L.D.S., of Crewe, to Mary Turner, M.B., Ch.B., D.P.H., eldest daughter of the late Martin and Amy Turner, of Manchester.

DEATHS.

Browne.—On Dec. 19th, at his residence, Lismore, Windsor-avenue, Belfast, Sir John Walton Browne, M.D., LL.D.

Chappel.—On Dec. 15th, at Clevedon, Altrincham, George Pester Chappel, M.D.

Lovell.—On Dec. 16th, at Ashburnham-road, Hastings, Walter Frederick Lovell, M.R.C.S., aged 74.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

## MEDICAL AND SANITARY WORK WITH THE BURMA CORPORATION.

By J. P. Cullen, M.D. Lond., D.P.H.,
MEDICAL OFFICER TO THE BURMA CORPORATION, NAMTU, NORTH SHAN STATES, BURMA.

Medical and sanitary work undertaken by private companies and corporations in outposts of the Empire is little heard of by the public at large. The latter labour under the impression that such companies exist solely for the benefit of shareholders, and have no other aim than that of paying dividends, and some account of the work of the Burma Corporation in other fields than those appertaining to the extraction of silver and lead from what is possibly the richest silver-lead proposition in the world may be of interest.

Geographical and Climatic Features of the District.

The Corporation's areas, situated in the northern Shan States of Burma, on the boundaries of the tropical zone, are, roughly speaking, 600 miles north of the port of Rangoon, and some 50–60 miles from the Chinese province of Yunnan, which supplies a large proportion of the native labour employed. Namtu, the headquarters, lies in the valley of the Namtu river, at an altitude of 1750 feet above sea-level. The other centres of activity are scattered partly along the main line of the Burma railways and partly along the Corporation-owned branch line, with its terminus at Bawdwin silver-lead mine. Over a large area of country the Burma Corporation attends to the medical and sanitary requirements of about 20,000 inhabitants, comprising Europeans and natives of all descriptions and colour. Taken as a whole, the climatic conditions of this area are not unfavourable; but Bawdwin, for example, situated at an altitude of 3000 feet, is less trying than Namtu at 1750 feet above sea-level. The monsoon season starts about May, and in the early days the combination of heat and moisture creates a certain amount of lassitude which passes off with the continued rainfall. The invigorating cold weather from November to March supplies the necessary stimulus for the succeeding hot months. The rainfall averages 60–70 inches per annum.

Public Health in General.

The European staff of the Corporation are accommodated in wooden bungalows, some of which are mosquito-netted. Electric light and water are laid on to each house, and while the majority are provided with a conservancy system of sewage disposal, some are connected up with small septic tanks. With an increased water-supply all the houses will probably soon be on a water-carriage system, and one of the most objectionable and insanitary features of Indian life will thus be removed. Accommodation for native employees varies from stone barracks for the coolie class of worker to houses built of wooden framework with matting walls and galvanised iron roofs for the better class. These houses are provided with pit or pail latrines, the number of which are calculated according to the population using them.

Water-supply.—Namtu at present obtains its water-supply from surface springs. The water thus obtained is open to the objection that it may be contaminated, though owing to the remoteness of human habitations such risk is probably slight. A greater objection is its hardness, which, besides causing trouble owing to deposit of lime salts in the reservoir pipe lines, has been shown to be a cause of diarrhœa, owing to the large proportion of magnesium sulphate derived from a dolomite formation. A new water-supply tapped at its source, and capable of yielding 190,000 gallons per 24 hours, and giving on a basis of 40 gallons per head a sufficient supply for a population of 4000–5000 people is now under construction. At Bawdwin mine and the other centres the water-supply is free from any risk of contamination.

Hospital Accommodation.—Infectious Diseases.

The medical staff comprises eight doctors, five being stationed at Namtu and the remainder at outlying stations. At Namtu the sanitary staff comprises two sanitary inspectors and 92 sweepers, at Bawdwin one sanitary inspector and 27 sweepers, and at the other centres in proportion to their requirements. All the sanitary inspectors hold the certificates granted by the Indian Boards of Examiners, know the native habits, and do their work efficiently and tactfully.

The Corporation's main hospital, reserved for Asiatic and Eurasian employees, and also subserving the large Government areas of Panghai and Ehaung, can accommodate 84 patients. It was opened in April, 1923, and comprises

(1) an administrative block containing offices for the chief medical officer and his chief assistant, an X ray room (with apparatus provided by Messrs. Watson and Sons, London), and a pathological laboratory equipped with microscopes, dark-ground illuminating apparatus, Cambridge rocking microtome, Garrow's agglutinometer stains and reagents, &c. ; (2) medical and surgical wards and dispensary ; and (3) a well-equipped operating theatre. In addition, there is a small separate European hospital of four male wards and one female ward. In the near future it is intended to amalgamate these two hospitals in order to increase efficiency and lessen cost. Outlying districts of importance contain small hospitals capable of accommodating three to four patients until such time as they can be safely transferred by rail to the central hospital at Namtu.

Epidemics have been carefully considered by the Corporation and its sanitary advisers ; the conclusion finally arrived at has been the building of a temporary hospital capable of rapid enlargement at a spot five miles out of Namtu, the policy being to provide accommodation which can be rapidly enlarged by the engineering staff in case of emergency, which can be destroyed after use, and which, being of a temporary nature, will require little upkeep and not fall into ruin from neglect for a period of years.

Effect of Foregoing Measures on the Health of the Population.

If, as has been stated, "the enteric fever mortality is the best test of sanitary condition, caused, as it is, by specific fæcal contamination of soil and water," then the sanitary state of the Burma Corporation is satisfactory, for no case of enteric has occurred during the past year. Cholera, which swept these valleys in 1918 and has again been reported in the northern Shan States, has not visited these parts for five years. Plague occurred in four cases in 1922. Two recovered, one after excision of a bubo in the groin, the other after intravenous injection of iodine. All cases were verified by bacteriological findings, and contacts were inoculated and kept under surveillance. The most effective measures dealing with the rat pest were found to be periodical rat drives. Trappings and poisoning were found unsatisfactory. No case of small-pox has occurred during the past three years.

Peculiar and Prevalent Diseases.

Of prevalent diseases, malaria undoubtedly holds the chief place, and the statistics are swollen to large figures when the native population is included. The natives are recruited not for their mental acquirements but for their capacity for hard manual work ; they only visit hospital when too ill to work. During 1922, 17,687 cases of malaria attended the various hospitals and dispensaries, with 100 deaths, or a mortality of 0·5 per cent. Amongst the European population only 22 cases were admitted to hospital, with no deaths. One case of blackwater fever was recorded in an Indian ; he had previously suffered from the disease, and recovered. Repeated blood examinations failed to discover the malarial parasite in this case. An examination of the urinary sediment revealed, however, short chains of streptococci. During the year popular lectures, including demonstrations of the malaria parasite, of anophelene and culex larvæ, and of children with greatly enlarged spleens were given. Two large swamps were drained, and mosquito brigades were organised. Malarial prevention is, however, an individual as well as a communal problem, and with an ignorant population progress is slow.

Relapsing Fever.—During the year 1922, 13 cases with one death occurred, the patient in this instance being in a very debilitated state when admitted to hospital. All the cases were met with among Chinese coolies from Yunnan, who arrive badly infested with lice. A delousing apparatus has been set up at Bawdwin, and each batch of coolies as it arrives is now deloused. The procedure was unpopular at first, but the Chinese, handled with tact, have come to realise the benefits of the method, and now submit readily. Medical treatment of the active disease consists in one or at the most two injections of neo-salvarsan. That relapsing fever can assume the nature of an epidemic, accompanied by a high mortality and giving grave anxiety to health authorities, is shown by the report on relapsing fever in the Madras Presidency in THE LANCET of August 4th, 1923.

Beri-beri.—This disease has been met with among the Chinese labourers. During 1922, 68 cases with 19 deaths occurred. Most of the cases were sporadic, but in one instance of 19 coolies attacked within a few days six died. On investigation it was found that the men had contracted with another Chinaman to feed them, the sole article of diet being polished rice. Samples of this rice, on analysis for phosphorus content, gave figures near or below the limit fixed by legislation. An improvement of the contractor's diet scale and a lessening of his profits followed.

Disease Traceable to Work in Mines.

Miners' Phthisis.—The Bawdwin mine is, in mining language, a "wet mine" and therefore free from dust. No case of pneumokoniosis or miners' phthisis occurred in it during 1922. The prevalence of pulmonary tuberculosis in Burma and the northern Shan States is a matter, however, that sooner or later will require investigation.

Ankylostomiasis.—Only two cases of this disease were met with in 1922, the worm, of the usual Eastern type, being discovered during a routine examination of fæces and not responsible for the patients' ill-health.

Plumbism.—This condition gave rise to much discussion during 1922. The difficulty of preventive measures for use in dealing with an ignorant class of labour was finally solved by the erection of a gigantic flue, the largest in the world, at a cost of ten lakhs of rupees. All fumes from the smelter are now taken up this flue by powerful suction apparatus instead of polluting the atmosphere at the mouths of the furnaces.

Venereal Disease is rampant in the tropics and Namtu is no exception to the general rule. No European should be allowed to come out east without plain warning of the risks incurred by promiscuous sexual intercourse, and he should be instructed in early treatment as carried out in the army. Much misery may be saved by a little plain talking. A knowledge of the prevalence of V.D. sometimes leads to curious errors in diagnosis, and salvarsan and its derivatives are still too frequently employed as diagnostic agents. Two cases of quaternary syphilis in natives came under observation during the past year ; one was of well-marked tabes following on insufficient doses of 914 (four injections), the other of thoracic aneurysm, showing post mortem well-marked naked-eye signs of syphilitic aortitis, and on section a gummatous mesaortitis.

Vital Statistics.

Whilst no satisfactory system of birth and death registration is in vogue throughout the area and the figure of 20,000 for the population is open to the criticisms attached to all floating populations, a few statistics are appended which may be of interest. The general or crude death-rate is estimated at 17·5 per 1000, as compared with 21·45 for the province (1922 report), and over 30 for British India as a whole. Malaria claimed a death-rate of 5 per 1000, and dysentery 0·75 per 1000. The mortality rate for plague was 0·1 per 1000, as against 0·516 for the whole province.

General Comments.

For such work as has been accomplished the sole credit lies with the management and the board of directors of the Burma Corporation, who have spared no trouble or expense. Much still remains to be done—e.g., the problems of a census of vital statistics, prompt notification of epidemics to a central authority, prompt distribution of the information so obtained, the ferreting out of latent foci of disease in out-of-the-way native villages, stricter vaccination, Government encouragement of research, and the opening up of a very rich country in order to provide the necessary financial support. Locally, the difficulty which confronted munition workers during the war—that of retaining maximum efficiency with maintenance of bodily health—faces us and will no doubt be tackled soon. A constant problem is to diagnose correctly the first case of any epidemic disease, the occurrence of which would entail a serious loss of revenue to the Government and Corporation.

ROYAL INSTITUTION DISCOURSES.

BIOLOGICAL sciences are to be well represented in the coming session at the Royal Institution. After Sir William Bragg's Christmas lectures on "The Nature of Things" (which he is naturally treating from the physical standpoint) and the tribute that is to be paid by Prof. H. E. Armstrong to the late Sir James Dewar, the programme of the Friday lectures will be found to have many points of contact with the medical profession. Prof. Hugh MacLean, in his discourse on insulin proposes to show why the previous attempts to isolate it failed. As full a description of its value and mode of application as is compatible with a lay audience will be given, and emphasis will be laid on its toxic action and the consequent need for very strict care in its use. In another discourse Prof. Elliot Smith will expound his views on the evolution of the human brain, emphasising the part played by the cultivation of vision and discussing how the human brain attained its distinctive feature—namely, the power of learning by experimentation, and the power of appreciating and interpreting the meaning of things and events in the outside world. Dr. Jocelyn Thorpe is discussing "Colours, Stains, and Dyes," and will point out how restricted Nature is in her way of forming colours, and how she relies more on physical than chemical means, the reason being that in coloured carbon compounds it is only the unsaturated molecules, which are very liable to change, that exhibit colour phenomena. As illustrations he will take the colours of the butterfly's wing, and of the feathers of many birds which depend on an arrangement of hair-like filaments so set as to reflect the required colour. Lastly, Sir Frederick Keeble is taking "The Plant Commonwealth and its Government" as his subject, and will deal with the new work that is tending to show the close relation existing between the tissues of plants. As in Sir James Dewar's time, the club rooms of the Institution will be open every Friday evening to members and their guests, for the exhibition of objects of scientific, literary, and artistic interest. Incidentally, the weekly exhibitions held during the sessions are a curious illustration of how ignorant the average Londoner is of his London. Many who attend the Friday lectures are unaware of their existence, and outside professional men of science there are few who realise that the Institution is essentially a club with a scientific and general library comprising some 60,000 volumes as one of its attractions.

CALENDARS AND DIARIES FOR 1924.

A CONVENIENT block calendar for 1924 has been issued by the Anglo-French Drug Co. (238a, Gray's Inn-road, London, W.C. 1.). There is provided for each day throughout the year a sheet of white paper four inches square for written memoranda, and the stiff hinged cover provided preserves the privacy of the notes, and yet by means of a window permits the date to be constantly seen. A certain number are available gratis on application to the company.

BIRTH CONTROL AND THE MINISTRY OF HEALTH.

AT a meeting held on behalf of Walworth Women's Welfare Centre at 43, Upper Grosvenor-street, London, on Dec. 13th, Lord Buckmaster presiding, it was moved by Dr. Elizabeth Sloan Chesser, seconded by Dr. Binnie Dunlop, and resolved, nem. con., that "This meeting represent to the Ministry of Health that it is desirable that no official opposition should be raised to the giving of birth control advice at any welfare centre, the medical officers of which are willing to give such advice."

We understand that the present attitude of the Ministry of Health in regard to birth control is :—

1. That the maternity and infant welfare centre should deal only with the expectant or nursing mother (and infant) and not with the married or unmarried woman contemplating the application of contraceptive methods.

2. That it is not the function of an ante-natal centre to give advice in regard to birth control, and that exceptional cases in which the avoidance of pregnancy seems desirable on medical grounds should be referred for particular advice to a private practitioner or hospital.

A MODIFICATION OF THE RINGLEB CYSTOSCOPE.

THE component parts of this modified cystoscope are : (*a*) The sheath carrying the lamp, and, in the catheterising model, catheter channels with an Albarran lever ; (*b*) the telescope ; (*c*) the obturator ; (*d*) the ball-valved spigot. The examining and catheterising sheaths are similar to those of the Ringleb model, with the important difference that the valve chamber and clapet valve are dispensed with, a simple metal collar with a compression flange taking the place of the former, and the clapet valve being replaced by the ball-valved spigot to be described later.

The advantages claimed for this modification are : 1. A complicated mechanism is replaced by a simple one, which is much less likely to give trouble. 2. The sheath is shortened, with the result that the telescope is correspondingly shorter, thus allowing (for the lens system used in this model) of better definition and brighter illumination. 3. Sterilisation of the instrument is easier, for the valve chamber and clapet valve are apt to collect mucus, blood-clot, &c., in the wiring of the spring and the interstices of the chamber, and to achieve efficient sterilisation of these parts by boiling entails very careful heating of the sheath for fear of damage to the wiring, whereas the ball-valved spigot is readily taken apart and boiled. 4. The cost of production is appreciably diminished. 5. Friction of the clapet-valve against the distal end of the telescope, a potent source of wear and tear, is obviated.

The telescope is provided with the upright and right-sided genito-urinary lens system, a detailed description of which may be found in "The Theory of Optical Instruments," by Elmsley and Swaine. The obturator is a plain, solid, metal rod of the same diameter as the telescope, with a serrated knob at the proximal end to facilitate handling. It fills the space usually occupied by the telescope and is introduced with the sheath into the bladder. The reasons for the addition of an obturator are two-fold. In the first place, it obviates all unnecessary manipulation of the delicate optical component, the latter being introduced only after all the preliminaries have been completed and the bladder is ready for examination ; and secondly, the addition of a solid metal rod to the thin sheath gives the latter more weight, a factor facilitating gentle and painless introduction after the manner of a sound.

The ball-valved spigot is composed of two parts screwed together, the distal end being cylindrical and fitting into the proximal opening in the sheath, and the proximal end being olive-shaped externally to take an irrigator or syringe nozzle, as the case may be. A weak, non-corrodible spring presses a metal ball-bearing of appropriate size against the anterior socket. This ball-valve allows the inflow of fluid into the bladder under weak pressure, but effectively prevents any back flow.

The modification described is of especial value in the child's cystoscope.

The instrument is made by the Genito-Urinary Manufacturing Company, of 64, Great Portland-street, London, and is illustrated in their current catalogue.

JOHN ALBAN ANDREWS, *M.C.*, F.R.C.S. Eng.

EXPOSURE TABLE FOR COOLIDGE X RAY TUBES.

A CONVENIENT exposure table in card form for the use of radiologists and others has been issued by Messrs. Watson and Sons (Electro-medical) Ltd. (43, Parker-street, Kingsway, London, W.C. 2). On one side of the card exposures are given for double-coated films, and on the other for X ray plates. Use of this card will help to standardise technique so that the results of separate observers may be made comparable. The exposures are based on a subject of average weight ; any considerable variation will necessitate a slight increase or decrease of the exposures given. The cards, which are very highly glazed, will be replaced when damaged or worn free of charge by the makers.

A SCIENTIFIC INVESTIGATION INTO VEGETARIANISM.[1]

THIS book is written in a fine flowing typically French style, and, apart from technical errors, such as the use of the term "hydrates of carbon" for "carbohydrates," is well translated. The book may truly be described as full of meat, but it is meat rather overdone. With many of the author's arguments we feel bound to agree, and these are calculated to do good. But certain other arguments are less convincing—for example, "Every objection disappears before these three laws which sum up the most important teachings of general physiology : (1) a food is a substance suited for transmitting matter and cosmic energy to animal organisms, which are incapable of profiting by their contact with the common environment to gather energy therefrom ; (2) vegetables alone, being supplied with chlorophyll, are capable of creating foods and food energy, &c. . . . . they alone can renew the stock of matter and energy on which the animals draw ; (3) in a word, the true food, in its pure source, is inevitably vegetable."

Surely, the evils of meat eating (or "necrophagy," as the author calls it) are rather quantitative than qualitative. There is excellent chemical evidence that meat supplies the necessary amino-acids far more readily than do plant proteins. Prof. Lefèvre himself is no mean athlete, as is clear from his description of his mountaineering exploits. He appears to be one of those who can utilise plant proteins profitably, and if he is better on a "vegetalian" diet, he should certainly stick to it.

X. Y. Z., whose disgust we share, has omitted to enclose his card.

St. Paul's Hospital.—Dr. Leonard Myer informs us that the attendances at St. Paul's Hospital for Skin and Genito-Urinary Diseases are 60,000 a year for venereal diseases. The figure 20,000 mentioned last week (p. 1353) applied to the last year at the old hospital, with its limited accommodation.

Kolmer's Infection, Immunity & Biologic Therapy

New (3rd) Edition

This new (3rd) edition of Dr. Kolmer's work is in fact a *new work*. The chapters on precipitins, agglutinins, and complement-fixation have undergone heavy revision, including the recent investigations by Dr. Kolmer and his colleagues on complement-fixation in syphilis and a new method based on these studies. New chapters have been added on hemagglutinins, bearing especially on their relation to blood transfusion; on serum reactions in syphilis other than complement-fixation reactions; on allergy in relation to infection and immunity, clinical allergy, allergic skin reactions, treatment of human allergies and the Schick test. The chapters on vaccine and serum therapy have been very largely rewritten and non-specific protein therapy included. An important new chapter is that on biologic therapy of tuberculosis as well as that on blood transfusion, giving considerable attention to methods for transfusion.

Infection, Immunity and Biologic Therapy. Octavo volume of 1210 pages, with 202 original illustrations, 51 in colors. By JOHN A. KOLMER, M.D., Dr. P.H., D.Sc. (Hon.), Professor of Pathology and Bacteriology in the Graduate School of Medicine, University of Pennsylvania. Cloth, 60s. net.

Books sent, Carriage Paid, on Receipt of Price.

VALENTINE'S PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Valentine's Meat-Juice

In **Hospital** and **Private Practice** during **Epidemics** and **in their own persons** when ill, **Physicians** have demonstrated the **Value** of **Valentine's Meat-Juice** in **Sustaining** and **Strengthening** the weakened **Vital Forces.**

Pneumonia *and* Influenza.

Cavalier Dr. Enrico Ballerini, *Late Surgeon to the Hospital of Rome, Italy:* "I have used VALENTINE'S MEAT-JUICE in the treatment of patients and also personally after having been ill with Influenza, and I must say it is an excellent tonic in conditions of great organic weakness. I have prescribed it with the greatest satisfaction for convalescents and invalids restricted to a liquid diet."

Edward C. Seufert, M.D., *Professor Histology and Pathology, Illinois Medical College, Chicago:* "I have always been a user of the valuable preparation, VALENTINE'S MEAT-JUICE. The best results that I have obtained from it have been in Typhoid Fever and Broncho-Pneumonia of Children. I believe that the samples sent helped to save the child of one of my students at the College."

For Sale by European and American Chemists and Druggists.

ROBERTS & CO., 76, New Bond St., LONDON, W.

Age and worthiness

Although the two may not be necessarily related, we suggest that a firm having one hundred years' experience in the production of Medical Plasters, must, by all the rules of survival have proved, in this case, that Age *does* go with Worthiness.

Our plasters are well-known and used in many of the leading hospitals and institutions throughout the country.

May we send you full particulars and prices?

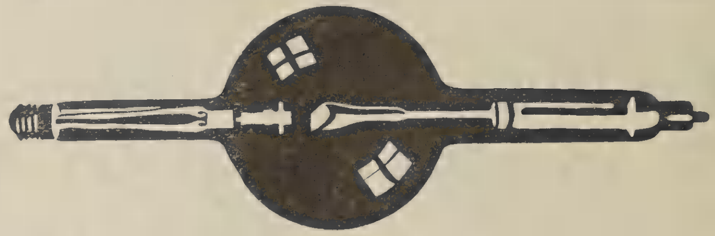
The Coolidge X-Ray Tube

Makes You Master of Your Apparatus



The Coolidge Tube is an instrument of scientific precision; an instrument of measured output and dependable performance.

When you employ a Coolidge Tube for any branch of X-ray work you remove a whole series of doubts and uncertainties. You eliminate a serious unknown factor. You replace rule of thumb by accurate scientific measurement.

The Coolidge Tube yields a measured quantity of rays of known penetration. It is constant under all conditions of voltage and current. It gives reliable performance for hours on end.

Uniformly perfect technique in radiography and accurate dosage in X-ray therapy are matters of course when a Coolidge Tube is used.

May we send you full particulars. All Types in Stock.

For Invalids and Convalescents

Horlick's Malted Milk presents the Proteids and Carbo-hydrates of Cereals and Milk in the proper ratio which affords a maximum of nutrition with a minimum tax on digestive effort. It materially assists the building-up processes by making good the wastage entailed by illness, accelerates the recuperation of the digestive and assimilative powers, thereby preparing the way to a resumption of a solid diet. Complete in itself and ready in a moment by briskly stirring the powder in hot or cold water only.

Liberal samples free to Members of the Profession.

The Management of an Infant's Diet

MELLIN'S FOOD contains 58.88 per cent. of Maltose.
MELLIN'S FOOD contains 20.69 per cent. of Dextrins.

A PROPORTION OF

MALTOSE & DEXTRINS

Best suited to the Carbohydrate needs of the average baby.

MELLIN'S FOOD contains 10.35 per cent. of Cereal Protein.

MELLIN'S FOOD contains 4.30 per cent. of Salts which consist mainly of Potassium Salts, Phosphatic Salts, and a small amount of Iron.

These facts should be considered in selecting a modifier of milk for infant feeding, for these facts indicate some of the reasons for the success of MELLIN'S FOOD which probably is unparalleled since the beginning of the study of the scientific feeding of infants.

HALITOSIS

(AS DEFINED IN THE CENTURY DICTIONARY)

(Hal-i-to-sis) N. N. L.

(L. Halitus—Breath :: Osis—Offensive)

Offensive breath, whether arising from diseased or neglected conditions of the teeth, mouth or nose or caused by disorders of digestion, respiration, the excessive use of tobacco, etc., may be readily overcome by the deodorizing properties of—

LISTERINE

Listerine is strictly antizymotic, it inhibits alike the acid fermentation of carbohydrates and the alkaline putrefactive processes of mixtures of meat and saliva, retained as debris about the teeth; hence, Listerine is antagonistic to the activating enzymes of fermentation so often the cause of Halitosis.

The volatile antiseptic constituents of Listerine-thyme, eucalyptus, gaultheria and mentha, combined with baptisia, boric acid, rectified spirits and water have a stimulating effect upon the stomach and in proportion to the dose, an action inhibitive to fermentation of its contents; hence, Listerine is often corrective of those disorders associated with the endo-development of gases and acid eructations. A large tablespoon of Listerine in a wine glass of hot water will afford immediate relief.

Intestinal Disinfection

No. 11.

MUCOUS AND OTHER FORMS OF COLITIS

Conditions of Colitis occur at all ages and lead to much suffering, ill-health and chronic invalidism. They are caused by a great variety of bacteria which owing to a loss of resistance on the part of the mucous membrane of the colon, maintain a chronic infection with inflammation of this portion of the intestinal tract.

Vaccine therapy is frequently tried in this condition with disappointing results, as it is pure chance if the causative organism is isolated from the host of bacteria present.

The rational treatment is obviously to administer an efficient germicide which will attack and destroy *all* the bacteria present. KEROL is the one substance which possesses this power and its administration has cured many a case of mucous colitis.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated) ; they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession

NEWARK

KEROL CAPSULES

A Simple, Durable Counter-Irritant

Musterole is an ideal counter-irritant. It can be applied to the chests of children in lieu of heavy and inconvenient poultices. It can be applied to the rheumatic joints of adults and to the skin over painful nerves. It is cleanly, efficacious and harmless.

Musterole contains oil of Mustard, camphor and menthol. It is a counter-irritant of mild degree, relieving pain and dispersing congestion. It plays the part of a poultice or fomentation over both of which it has the great advantage of simplicity and durability.

Thos. Christy & Co.,
4–12, Old Swan Lane,
London, E.C. 4.

MUSTEROLE

Are You Discouraged—

BECAUSE of those stubborn cases of maldevelopment, cretinism, retarded mentality, and epilepsy in children who come to

YOU for help ? Unless there are definite changes in the cerebral cortex, the child is undoubtedly suffering from a glandular derangement.

HAVE you ever wondered why some defective children respond well to thyroid, while in the majority of cases this same treatment has

FAILED entirely ? The thyroid, pituitary, and thymus glands are very intimately related in the causation of developmental dystrophies. It is therefore wise

TO use a pluriglandular treatment including all, rather than only one, of these principles.

SECURE the best results with the best pluriglandular formula.

RESULTS —permanent, beneficial results—have been obtained in many hundreds of cases, from " backwardness " to grand mal, by the use of

ANTERO-PITUITARY CO. (Harrower)

—containing anterior pituitary substance in generous dosage, thymus gland, and a small dose of thyroid.

A Helpful Adjunct to the Dietary in Fevers

OVALTINE

TONIC FOOD BEVERAGE

Contains Malt, Milk and Eggs, Flavoured with Cocoa.

IN the dietetic treatment of infectious diseases a suitable system of feeding is of the greatest importance. The gastric digestion, impaired by pyrexia and toxæmia is unable to tolerate the usual foods, and the patient's distaste for the ordinary forms of liquid feeding is notable.

"Ovaltine" added to milk furnishes an ideal liquid nutrient. The presence of "Ovaltine" renders the milk attractive to the palate, easily digestible and materially increases its nutritive power. The caloric value and chemical analysis of "Ovaltine" are shown below.

Protein, fat and carbohydrate are present in "Ovaltine" in properly balanced proportions and in a soluble and readily assimilable form. Experience in every day practice confirms that "Ovaltine" supports and increases the patient's strength in a most desirable manner.

Analysis.

Protein	14.2%
Fat	8.01%
Sol. Carbohydrates—	
Reducing Sugars	60.1%
Dextrin	7.8%
	67.9%
Insol. Carbohydrates	nil.
Ash	3.76%
Organic Phosphorus calculated as P_2O_5	1.18%
Diastasic Power	25° L.

The Administration of Ferrous Carbonate in a NASCENT state

THE efficiency of Blaud's Pill depends upon the reaction taking place in the stomach when the newly-formed ferrous carbonate is at once absorbed by the acid. For this purpose a means of keeping the alkaline carbonate and the iron sulphate separate until the stomach is reached has been found and takes the form of gelatin capsules divided into two compartments. These are called

BI-PALATINOIDS

THE LANCET says : "The employment of Bi-Palatinoids places the administration of exceedingly unstable compounds like ferrous carbonate, phosphate and arsenate upon a sounder and more scientific basis."

The Scientific Grants Committee of the British Medical Association instituted a research into the treatment of anæmia and chlorosis, under the supervision of a well-known physician. In his report the following appears : "So far as these observations go, they show that carbonate of iron in the form of the bi-palatinoid of Blaud Pills gave the best results compared with other preparations of iron containing an equivalent amount of the metal.

British Headquarters for
SCIENTIFIC ORGANOTHERAPY

Day by day, for fourteen years, these products have been stringently tested in the Crucible of the Clinic. As a result they are now the most extensively prescribed Endocrine preparations in Great Britain.

LYMPHOID COMPOUND.

A pluriglandular preparation with Spermin as its base and put up in soluble gelatine capsules. Widely prescribed, with exceptionally gratifying results, in Neurasthenia, Nervous and Mental Instability, Neuroses, Psychoses, Shock, Insomnia and in conditions resulting from glandular insufficiency, metabolic disorder, imperfect oxidation, impairment of nutrition, Fatigue and Exhaustion, and Impotentia.

LYMPH SERUM.

A pluriglandular product for hypodermic injection, the base of which is Spermin. Employed with great success in combating nervous disorders and in arresting, by compensation, organic degeneration. It has proved especially useful in the treatment of Locomotor Ataxia, Disseminated Sclerosis, Cerebral Degeneration, and Impotentia.

OVAMAMMOID COMPOUND.

A product of great service, the professional demand for which (as in the case of the other products) is extensive and constant. Put up in soluble gelatine capsules, and having for its base Ovarian Extract and Mammary Gland Extract of maximum activity, it compensates for Ovarian Insufficiency, combats conditions resulting therefrom, secures normal menstrual functioning and controls the disturbances of the menopause.

*** Also supplied in ampoules for Hypodermic injection.**

EUKINASE.

A scientifically prepared product containing the entire condensed duodenal juice in a dried state and in an active and unalterable form. It contains in a maximum degree of activity the digestive ferment Enterokinase and Secretin. This product is employed with gratifying results in the treatment of Duodenal Insufficiency and conditions arising therefrom, Constipation, Intestinal Indigestion, Pancreatic Insufficiency, Gastro-Intestinal Insufficiency, Infantile Diarrhœa and Fermentation, Diarrhœa of Adults, Steatorrhœa, Coprostasis, Dyspepsia, Flatulence, Nausea, Anorexia, Emaciation, and Glycosuria and conditions which have responded well to this product.

HÆMATOTHYROIDINE.

A trustworthy product employed successfully in the treatment of Exophthalmic Goitre. It is scientifically prepared from materials derived from the Serum (together with all the active principles extracted from the blood) of thyroidectomised horses.

EVATMINE FOR ASTHMA.

A dependable preparation supplied in ampoules for hypodermic injection, which contains, among its ingredients, Adrenin and Post Pituitary Ext. It secures complete control in Asthmatical Paroxysms in five minutes or less, usually after one injection and produces no adverse reactions. Free supplies for testing if desired.

TYPICAL LETTERS OF APPRECIATION FROM BRITISH MEDICAL PRACTITIONERS READ AS FOLLOWS :—

LYMPHOID COMPOUND.

"I am more than satisfied with your Lymphoid Compound. I have now prescribed it in 90 cases of Neurasthenia. The product has proved invaluable in my cases of Neurasthenia, Fatigue and Exhaustion, and Nervous Instability. It has not failed in a single case."

—M.R.C.S., L.R.C.P. (Lond.)

OVAMAMMOID COMPOUND.

"I have obtained such remarkably good results by your Ovamammoid Compound in my cases of Climacteric Disturbance, Dysmenorrhœa, and Menopausal Obesity, that I always prescribe it for such cases."

—M.B., Ch.B.(Edin.).

EVATMINE.

"I have been treating a very intractable case of Asthma with your preparation 'Evatmine.' The patient had been a severe sufferer for years, and the case had refused to respond to any other method of treatment. The patient obtained instant relief and a good night's rest after the first injection. Two further injections gave the same excellent result. It is six months since she had the last injection, during which time she has not had a single attack of asthma. Such a result is indeed remarkable."—M.D., B.Ch. (Edin.).

SUPPLIED TO PRACTITIONERS OR ON THEIR PRESCRIPTIONS ONLY.

THE BRITISH ORGANOTHERAPY CO., LTD., makes a speciality of meeting the constantly growing demand by Medical Practitioners for Pluriglandular products to their own formulæ (with or without the inclusion of Pharmacopœial adjuvants), for the treatment of individual cases. These compounds are dispensed from FRESH MATERIALS, at short notice, and at reasonable rates.

Interesting literature, monographs in respect to any phase of Modern Organotherapeutics, Suggestions for treatment and authentic clinical data sent on request.

SCHWEITZER'S

COCOATINA

(British Manufacture)

THE PERFECT BEVERAGE.

COCOATINA is the product of the finest selected Cacao beans, and is prepared by a process which effects the removal of the excess of fat and the neutralisation of the free acids, the final product being obtained in the form of an impalpable powder.

⁂

The elimination of the superfluous fat enables COCOATINA to be taken by persons who cannot tolerate ordinary Cocoa, whilst its neutrality and extreme fineness render COCOATINA perfectly miscible with water or milk.

SCHWEITZER'S
COCOATINA
The most nourishing and digestible of all beverages
BRITISH
SCHWEITZER'S
TRADE
MARK
COCOATINA
MANUFACTURE.
COCOATINA is sold in Great Britain in tins at 1s. 6d. and (three times the quantity) at 4s.
Wholesale only of FLETCHER, FLETCHER & Co., Ltd., Vibrona Laboratories, LONDON, N. 7

COCOATINA being free from tannin, does not prevent the digestion of animal food, as is so frequently the case with both tea and coffee.

⁂

COCOATINA, made with equal parts of boiling water and milk, possesses all the properties of an ideal food beverage.

⁂

Half-a-teaspoonful of COCOATINA is sufficient for a breakfast cup. A larger quantity is not only unnecessary and wasteful, but impairs the delicate aroma and flavour of the beverage.

The value of Schweitzer's Cocoatina has been fully recognised by the Medical Profession for over 50 years, and its claims have been endorsed by many of the most eminent authorities on dietetics. Schweitzer's Cocoatina is so highly Concentrated that half-a-teaspoonful is amply Sufficient for a breakfast cup.

Supplied in tins at 1/6, sufficient for 80 breakfast cups and (three times the quantity) at 4/-.

Sample tin free on application to **FLETCHER, FLETCHER & Co., Ltd., Vibrona Laboratories, Holloway, LONDON, N. 7.**

EVERY BATCH OF CATGUT IS
PASSED BY A CONSULTING BACTERIOLOGIST
BEFORE IT IS ISSUED

LONDON HOSPITAL CATGUT

Each box of sterile "Ultratan" Catgut for surgical work bears a label stating that "every batch of catgut is passed by a consulting bacteriologist before it is issued."

"Ultratan" Catgut is prepared at the London Hospital, and is in continuous use in the 15 operating theatres there.

It is claimed for
London Hospital Catgut:

1—Sterilisation commences immediately the intestine is split.
2—The tensile strength provides a wide margin of safety.
3—Every batch is passed by a consulting bacteriologist.

PORTRAITS OF HITTITE EMPIRE BUILDERS CARVED BY THEIR CONTEMPORARIES OF THE SAME RACE.—The ethnic affinities of the Hittites remain as yet unknown. Their personal appearance, as we see it on their own and on Egyptian monuments, is unlike that of any other people. Their facial type is neither Semitic nor Aryan, and while some authorities see in it, in some cases, certain Mongolian features, and, in others, indications of a proto-Greek type, both these suggestions are warmly contested. Individuals resembling the Hittites are common in Eastern Anatolia among the Armenians of the present day, and the name "Armenoid" has been given to the type, which seems to represent a well-defined ethnic group. Its seems likely that the Armenians may be the modern representatives of an old stock, and that the survival of the type may be due to life through long ages in remote mountain villages with little intermixture with other races. The Hittites are noticeable from their extreme brachycephaly and their high and narrow nose in a line with their retreating forehead. They bear a certain resemblance to the Jews. We have, as yet, no ancient Hittite skulls. The pure Northern Hittites of the accompanying illustration wear no hair on their faces; they generally have a pig-tail, and are short, thick-set and evidently very hardy. To some investigators the Hyksos, who descended upon Egypt towards the end of the 18th Century B.C., were the Hittites, while, to others, they were Syrians, who, pressed by the Hittite "push," were driven to the Nile valley. But all conclusions as to the origin, race and language of the Hittites are at present provisional.

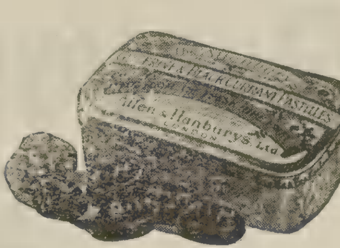
The 'Allenburys' PASTILLES

Glycerine and Black Currant Pastilles

Delicate in flavour. *Efficient in use.*

They are manufactured from pure glycerine and the fresh juice of choice ripe black currants by a special process which conserves the full value and flavour of the fruit. The 'Allenburys' Glycerine and Black Currant Pastilles have a demulcent and mildly astringent effect, most useful in allaying simple irritations of the throat. They dissolve slowly and uniformly, and have a delicious and slightly acidulous flavour.



Supplied in metal boxes containing 2 ozs., 4 ozs., 8 ozs. and 1 lb. respectively.

The 'Allenburys' Medicated Pastilles

may be relied upon to present the accurate amounts of the active ingredients and to be thoroughly effective in use. They dissolve slowly and uniformly, ensuring a thorough suffusion of the medicament over the mucous membrane. 81 varieties of the 'Allenburys' Medicated Pastilles are manufactured.

Descriptive Booklet and Price List sent on request to members of the Medical Profession.

Packed in original tin boxes containing [illegible] ozs., 8 ozs., and 1 lb. respectively.

FINEST NATURAL STIMULANT
for Anæmia, Debility and Convalescence

Ever since TINTARA, ferruginous, was introduced in 1871, it has been highly recommended by the Medical Profession in all cases where strength and nerve force have required building up. In anæmia, debility, neurasthenia and in convalescence after any illness, this full-bodied, generous wine, palatable as well as health producing, has proved itself the finest of all natural stimulants.

This is because Tintara is grown on the wonderful ferruginous (ironstone) soil and beneath the glorious sunshine of Australia and is absolutely pure and unmedicated. It contains no added spirit.

Burgoyne's
Tintara

Ferruginous.

THE LANCET says: "*This is a typical Australian red wine, full-bodied, and of rich colour. It approaches in character, comparing it with European wines, the Burgundy of France, and its analysis gives similar results. The grapes produced in Australia are of a luscious character, and accordingly the product is, as a rule, of a generous description. In our opinion these wines in regard to flavour are often more appreciated when slightly diluted with water. The taste then is mellow and quite non-acid, and resembles that of the similar French wines closely. Adding water, of course, means thinning the full-bodied wine down to one of a more delicate kind. Thin, delicate wines do not, as a rule, bear dilution well. The robustness of this wine is evidenced in the analysis. The mineral matters contained distinct quantities of both phosphates and iron. The wine is the genuine fermented product of the grape, and is thoroughly wholesome.*"

"TINTARA" BURGUNDY FERRUGINOUS can be obtained from all wine merchants in flagons or bottles. The "Burgoyne" flagon is equivalent in quantity to one and a half bottles, and the screw stopper facilitates its use.

Sample Bottle sent free in the United Kingdom, on receipt of professional card.

DESOUTTER BROS. L$^{\text{TD.}}$

MAYFAIR 4332. 73, BAKER ST., LONDON, W. 1

THE RECOGNISED LIGHT METAL LEG SPECIALISTS.

More Desoutter Light Metal Legs are being supplied to-day than all other makes put together.

"Vide Extracts from the Report of the Ministry of Pensions Committee of Inquiry on Artificial Limbs reproduced below."

" With regard to (*a*) the fitting of the metal bucket of the 'Desoutter' limb to the stump is a matter of personal skill and technical manipulation of the metal which is at present confined to one or two persons in Mr. Desoutter's own establishment in London."

"The Desoutter and/or other approved light metal limbs should be placed upon the Consolidated list, and should be made available for all new cases in which the surgeon recommends these on surgical or other grounds instead of the standard pattern wooden legs."

Please write for a Copy of the Report and full particulars of the Desoutter Leg.

7 Surgical Reasons why the Desoutter Leg is essential:

1. The patent vertical joint on pelvic band which allows free rotation of trunk of body.
2. The patent swivel stirrup on bucket by which the leg is supported centrally, and which allows perfect freedom for swinging the leg from side to side.
3. The hygienic perforated bucket finished in glazed enamel, ensuring health, coolness, and cleanliness for the stump.
4. Its lightness, demanding the minimum amount of energy from the wearer.
5. Its scientific design and construction, assuring the safety of the knee when walking.
6. The great personal care combined with our patented scientific method of fitting each leg.
7. Its perfect balance or distribution of weight—*i.e.*, the limb being very light below the knee joint greatly facilitates walking.

The lightest, strongest, and most comfortable leg made.

Average weight for above knee amputation 3½ lb.

DEAFNESS IN PRIVATE PRACTICE

RECENT letters received by Mr. Dent from Medical Men in private practice suggest that the following information concerning the nature and scope of the "**ACOUSTIQUE**" may be welcomed where an opportunity for a thorough personal investigation has so far not arisen.

There are 28 distinct types of the "**ACOUSTIQUE,**" each separately designed for a specific condition of ear trouble and capable of further minute adjustment in each case.

The selection of an appropriate type is based upon the personal information of the physician or indicated in his prescription.

Individual adjustment is subsequently made as a practical test suggests. For this purpose it is eminently desirable that a personal visit from the patient is arranged.

Many physicians prefer to be present during these tests and their presence is at once welcome and obviously helpful.

The "**ACOUSTIQUE**" is fitted with an exclusive NON-HEAD ATTACHMENT and is practically invisible.

Its unquestioned superiority and efficiency is indicated by its widespread acceptance by leading Aural Specialists, by whom it is exclusively prescribed both in private and hospital practice.

Mr. Dent will gladly send full information of the various types of "**ACOUSTIQUE**" and medical reports to any Doctor, and is at all times pleased to arrange for a personal demonstration of the "**ACOUSTIQUE**" either at 95, Wigmore Street, or at any of his branches, and will be pleased to consider any suggestions.

An exclusive speciality is the "**ACOUSTIQUE**" **STETHOSCOPE** which embodies all the virtues of the other types of "**ACOUSTIQUE**" and enables deaf members of the Faculty to continue their good work. Of this, a well-known heart Specialist, writing from Malta, says: "The "**ACOUSTIQUE**" (STETHOSCOPE) has been a godsend to me."

An appointment is desirable.

Our little Booklet, "MEDICAL PRESS OPINIONS," will be sent free on application and contains reprints of reports on "ACOUSTIQUE" by the—
BRITISH MEDICAL JOURNAL, LANCET, PRACTITIONER, MEDICAL PRESS AND CIRCULAR, EDINBURGH MEDICAL JOURNAL, GLASGOW MEDICAL JOURNAL, CLINICAL JOURNAL, GUY'S HOSPITAL GAZETTE, etc., etc.

On the suggestion of Hospital Practitioners at the recent **B.M.A. MEETING,** Mr. R. H. Dent has devised some new types of "**ACOUSTIQUE**" to meet the needs of Hospital Patients and others of limited means, at prices ranging from 3½ GUINEAS.

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.

SANTAL · MIDY

There is a marked absence of Gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permit its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-urinary Tract. The capsules contain 5 drops, and usually [illegible] to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Vivienne, Paris, and sold by most Chemists and wholesale Druggists throughout the world.

U.K. Agents: WILCOX, JOZEAU & CO., 15, Gt. St. Andrew St., W.C.2.

PYRAMID NIGHT LIGHTS

Into the World

Baby's change of environment is sudden and serious. It demands preparation and constant care. The soundest course is for the Mother to take **Cow & Gate Milk Food (Full Cream)** regularly before and after birth.

This Food, also sold in Half Cream, is proved by independent tests to be the most reliable form in which all the necessary elements can be assimilated. Prepared from the milk of selected English herds, softened and adapted to the feeblest digestion, it makes nursing the greatest maternal joy.

The Half Cream is most suitable for direct feeding to infants up to three months of age.

Each forms a complete and pleasing dietary.

THE SAFE ANÆSTHETIC

ETHANESAL

Ethanesal has been proved to possess the following advantages :—

(1) It is not irritating to the respiratory passages.
(2) After smell and taste are absent.
(3) Deep anæsthesia is unnecessary.
(4) Muscular relaxation resembles that produced under chloroform.
(5) There is very slight abdominal movement owing to the quieter respiration.

Antiphlogistine poultice, some hours after application to inflamed area. Centre is moist, where exudate has been drawn from the congested tissues. Periphery, covering normal surrounding tissues virtually dry.

This chart shows the Osmotic action of Antiphlogistine

DIAGRAM represents inflamed area. In zone "C" blood is flowing freely through underlying vessels. This forms a current away from the Antiphlogistine whose liquid contents therefore, follow the line of least resistance and enter the circulation through the physical process of endosmosis.

In zone "A" there is stasis, no current tending to overcome Antiphlogistine's hygroscopic property. The line of least resistance for the liquid exudate is therefore in the direction of the Antiphlogistine. In obedience to the same law, exosmosis is going on in this zone, and the excess of moisture is thus accounted for.

Antiphlogistine generates and retains heat upwards to 24 hours

Due to the chemical reaction which goes on during Osmosis between the c. p. glycerine of Antiphlogistine and the water of the tissues, Antiphlogistine keeps up a steady heat generation.

This sustained heat is invaluable; relieving congestion by increasing superficial circulation, stimulating the cutaneous reflexes, and causing contraction of the deep-seated blood vessels.

Used by hundreds of thousands of physicians the world over.

Antiphlogistine stands alone as a non-toxic, non-irritant abstractor of fluid exudates in superficial inflammations. It relieves deep-seated congestion by inducing superficial hyperemia, through its inherent hygroscopic property, and without irritation.

Let us send you our free booklet "The Pneumonic Lung." Address The Denver Chemical Mfg. Co., London, E. 3. Branches: New York, Sydney, Berlin, Paris, Buenos Aires, Barcelona, Montreal.
